more. Traditional power system quantities such as effective value, power (active, reactive, apparent), and power factor need to be numerically calculated from sampled voltage and current sequences by performing DFT or FFT algorithm.

Having in mind that voltage waveform almost insignificantly deviates from sinusoidal (typically $THD_V < 3\%$), we will focus only on current waveform.

We will review some basic definitions briefly. The RMS value of current is calculated according to the well-known formula:

$$\tilde{I} = \sqrt{\frac{1}{\mathrm{T}} \int_{t_0}^{t_0+\mathrm{T}} \left(i(t)\right)^2 dt} \tag{1}$$

where $i(t)$ represents instantaneous current, T is the period and t_0 is some arbitrary time. We can develop Fourier representation:

$$\begin{aligned} i(t) &= a_0 + \sum_{k=1}^{+\infty} \left(a_k \cdot \cos\left(k\omega t\right) + b_k \cdot \sin\left(k\omega t\right)\right) \\ i(t) &= i_0 + \sum_{k=1}^{+\infty} i_k \cdot \cos\left(k\omega t + \psi_k\right) \end{aligned} \tag{2}$$

where $i_0 = a_0$ represents DC component, $i_k = \sqrt{a_k^2 + b_k^2}$ amplitude and $\psi_k = \arctan\frac{b_k}{a_k}$ phase of the k^{th} harmonic. $\omega = \frac{2\pi}{\mathrm{T}}$ represents angular frequency.

The Fourier coefficients a_k, b_k can be calculated as:

$$a_0 = \frac{1}{\mathrm{T}} \int_{-\mathrm{T}/2}^{+\mathrm{T}/2} i(t)dt, \quad a_k = \frac{2}{\mathrm{T}} \int_{-\mathrm{T}/2}^{+\mathrm{T}/2} i(t) \cdot \cos\left(\frac{2k\pi t}{\mathrm{T}}\right) dt \tag{3}$$

and

$$b_k = \frac{2}{T} \int_{-\mathrm{T}/2}^{+\mathrm{T}/2} i(t) \cdot \sin\left(\frac{2k\pi t}{\mathrm{T}}\right) dt. \tag{4}$$

The RMS value of the k^{th} harmonic, further used for ANN training, as well as for identification, is:

$$\tilde{I}_k = \sqrt{\frac{a_k^2 + b_k^2}{2}}. \tag{5}$$

As we are dealing with discrete sets of values obtained by sampling, harmonic analysis is achieved by software implementation of some FFT algorithm.

III. ANN TRAINING AND LOAD IDENTIFICATION

For the purpose of this paper, we used current harmonics up to 40$^{\text{th}}$ harmonic. Since even harmonics are not present in the spectrum of most electronic devices (as well DC component), only odd harmonics are considered. In this analysis, only amplitudes are taken into consideration.

The measurement is performed on 12 different combinations of various devices, shown in the Table I. We took into account devices that are typical for an office, for example. In fact, we have one PC, one server, one monitor, one kettle, one LED bulb, and an air-condition that can be in two operation modes: cooling and heating. Both the PC and the server operated with idle CPU utilization in all cases, so they can be treated as stationary nonlinear loads with constant power consumptions and current waveforms. The codes are given in the first column of the Table I, and also in the first row of the Table II. First column of the Table II gives the order of the harmonic.

TABLE I
CHARACTERISTIC COMBINATIONS OF THE DEVICES

Code	Device
1	Led Bulb
2	Kettle
3	Server
4	Air-condition heating
5	Air-condition cooling
6	PC + Monitor
7	Server + PC + Monitor
8	Server + PC + Monitor + Kettle
9	Server + PC + Monitor + Led Bulb
10	Server + PC + Monitor + Air-condition heating
11	Server + PC + Monitor + Air-condition cooling
12	Server + PC + Monitor + Air-condition heating + Led Bulb

Artificial neural network needs to be trained for modeling the look-up table. It is a feed-forward neural network with one hidden layer. The measured values from the Table II are inputs to the network, and the Code is network output to be learned. It means that the neural network has twenty input neurons and one output neuron. After training was completed, the number of hidden neurons in the resulting ANN was two, what was found by trial and error after several iterations starting with an estimation based on [6] and [7]. The training error was 3.16916e-017.

This number of hidden neurons in the neural network is very small. This opened a question if twenty input neurons were really needed, or we can train a neural network with smaller set of data. So, we tried to reduce training set to ten inputs. After training was completed, the number of hidden neurons in the resulting ANN was also two, and the error was very small, 2.68838e-019. Next step was to reduce training set to five inputs. We first tried to train an ANN with two hidden neurons, but it was not possible because training error was unacceptable. Then we enlarged the number of hidden neurons to three, and training results were good, the training error was 1.9106e-015. We concluded that we could use five input neurons, but in that case, there were three hidden neurons needed.

So, when we compare the obtained networks, the first one has 20 input and 2 hidden neurons, the second has 10 input and 2 hidden neurons, and the last has 5 input and 3 hidden neurons. The simplest realization would be to realize the third network. It also requires the smallest set of measured data.

TABLE II

VALUES OF HARMONICS' AMPLITUDES ($\tilde{I}_k\,[\mathrm{mA}]$) FOR THE COMBINATIONS GIVEN IN TABLE II

code → harmonic (k)↓	1	2	3	4	5	6	7	8	9	10	11	12
1	43.24	7450	280.47	3460	3420	235.57	742.57	7990	609.35	3230	2980	3710
3	32.18	22.44	38.09	123.5	215.32	104.12	77.65	27.86	110.79	161.32	211.11	178.84
5	21.22	175.98	33.66	569.31	582.51	51.27	93.59	182.57	44.16	585.62	516.69	553.6
7	20.75	143.29	17.19	266.65	234.98	29.13	34.95	177.49	72	245.08	251.75	231.13
9	20.49	11.72	7.53	39.89	43.92	2.76	8.18	9.86	35.35	35.06	40.04	75.64
11	16.66	6	7.27	28.5	31.05	4.26	8.72	9.69	10.41	15.68	10	35.75
13	14.59	42.15	6.08	25.35	26.21	16.65	28.23	45.23	19.5	25.21	25.75	15.84
15	13.53	6.4	6.23	7.43	8.27	10.28	15.89	10.66	15.74	11.47	12.02	26.5
17	10.71	5.66	5.75	10.03	10.5	2.51	9.66	5.83	13.98	6.88	10.34	5.52
19	8.84	4.86	3.47	2.71	3.1	3.61	1.8	4.41	7.39	8.62	9.95	6.04
21	8.49	7.59	5.19	5.53	3.66	8.39	16.43	11.31	16.39	3.75	7.79	6.47
23	7.18	2.45	2.83	1.7	0.93	3.77	3.96	5.78	5.65	3.09	3.9	7.79
25	6.16	3.14	4.61	1.5	1.22	2.64	6.94	9.15	2.38	5.7	7.31	6.37
27	5.98	3.28	4.38	1.13	0.85	2.3	3.08	11.36	3.43	7.05	8.05	0.94
29	4.98	1.63	2.98	0.8	0.34	2.58	5.74	5.65	8.32	4.91	5.7	10.59
31	4.26	1.13	2.79	0.56	0.4	2.71	8.96	7.06	11.22	8.41	8.32	10.88
33	4.12	0.78	1.38	0.48	0.46	1.13	5.46	5.18	3.56	7.82	7.42	2.19
35	3.45	0.94	0.4	0.31	0.17	1.81	5.33	3.67	6.03	3.73	4.97	7.82
37	3.07	0.49	0.87	0.27	0.37	2.39	3.93	2.16	7.59	4.07	3.36	4.08
39	3.23	0.21	0.77	0.24	0.15	0.73	3.42	1.21	4.19	1.78	2.35	4.05

The structure and the parameters of both obtained ANNs are verified by exciting the ANN with the given inputs. Responses of the ANN show that there were no errors in identifying the codes what is presented in the Table III. Negligible discrepancies may be observed.

TABLE III

ANN OUTPUT CODES

Expected Code	ANN Output (20 hidden neurons)	ANN Output (5 hidden neurons)
1	1.00002	1.00005
2	2.00003	2.00007
3	3.00002	3.00007
4	4.00003	4.00023
5	5.00003	5.00009
6	6.00002	6.00008
7	7.00001	7.00008
8	8.00002	8.00008
9	9.00001	9.00006
10	10	10.0001
11	11	11.0001
12	12	12.0001

Also, we used one more way to verify this neural network. Namely, we measured all the harmonics when all devices were operating at the same time (Table IV). This in unknown situation for the network, because this data were not used in the training process.

So, this was used as an excitation to the network with 20 inputs. The response of that network was 11,71. This value is closest to 12, giving us information that a combination similar to combination 12 is working. When we check the Table I, we notice that this is correct, while all devices except Kettle are included in combination 12, what is the closest to situation when all devices are operating at the same time. Of course, we cannot have an exact information, but it can be useful in the diagnosis process.

TABLE IV

VALUES OF HARMONICS FOR ALL DEVICES OPERATING AT THE SAME TIME

k	1	3	5	7	9	11	13
$\tilde{I}_k\,[\mathrm{mA}]$	11400	124.58	692.57	299	65.53	22.38	46.06

k	15	17	19	21	23	25
$\tilde{I}_k\,[\mathrm{mA}]$	30.16	4.19	11.79	15.75	14.58	14.28

k	27	29	31	33	35	37	39
$\tilde{I}_k\,[\mathrm{mA}]$	4.81	9.84	10.69	3.04	3.47	4.41	3.68

IV. Conclusion

Most of the known NILM methods for identification devices use artificial neural networks. We have shown one implementation of such method, with current harmonic amplitudes used as ANNs inputs. In our previous work, different definitions of power were used – active, reactive and distortion power. Having in mind that the powers are calculated from voltage and current harmonics, we have concluded that information that characterizes nonlinear loads encoded in those parameters also exists in harmonics.

Although we concluded that we needed only 5 measured harmonics (1^{st}, 3^{rd}, 5^{th}, 7^{th}, 9^{th}), but only for this specific case. This means that in some other situation, when measured values of harmonics have less distinguished values, we would need more input values in order to better distinguish which consumer is on the network.

In this stage of our work, we have deliberately neglected harmonics' phases, which also contains some information of nonlinear load. The development of the method for identification and classification that takes harmonics' phases into account is the next logical step.

Acknowledgment

Results described in this paper are obtained within the project TR32004 founded by Serbian Ministry of Science and Technology Development.

A Flexible FPGA-Based Data Acquisition System with Integrated ADCs and 32-bit RISC-V Softcore

Nikola Ž. Petrović, *Student Member, IEEE,* and Vladimir M. Milovanović, *Senior Member, IEEE*

***Abstract*—A general purpose low-cost data acquisition system which includes integrated 12-bit analog-to-digital data converters (ADCs) and a 32-bit RISC-V soft microprocessor implemented on an FPGA-fabric is presented. Major part of the proposed system is not conceived as an instance, but rather as a design generator and is hence described in Chisel hardware construction language. The use of such a modern generator-oriented language enables extreme flexibility through comprehensive set of parameters and rapid system customization approach. The open instruction set architecture core that can be exploited for custom data processing is also obtained from the free Rocket System-on-Chip generator together with a standard set of peripherals thus supporting various connectivity interfaces and protocols. A prototype data acquisitioner is built around commercially-available Arty development platform which features internal 1 MSPS dual-channel ADC and its operation as a low-end oscilloscope is demonstrated.**

***Index Terms*—ADC, Chisel, RISC-V, Rocket, System-on-Chip, TileLink.**

I. Introduction

THE RISC-V specification is a royalty-free Instruction Set Architecture (ISA) standard for low-cost processors aimed to support architecture research and education [1]. The specification defines 32-bit, 32-bit embedded, 64-bit, and 128-bit base ISAs and optional extensions for compressed, multiplication, atomic, single, double, and quad-precision floating point instructions. RISC-V ISA is easily portable between different development environments and highly flexible to match the requirements of different applications. These features made RISC-V natural choice for FPGA softcore processor and that led to its adoption in academia and industry alike and an overwhelming proliferation of projects. For example, UC Berkeley provides open-source Rocket-chip System on a Chip (SoC) generator, which has been successfully taped-out over a dozen times in multiple different modern technologies by multiple groups [2], [3]. Also, Craft2-chip from UC Berkeley is freely available as a github repository. Company SiliconFive offers both open-source SoC generator for FPGA and commercial RISC-V IPs. Finally, in [4] and [5] processors are reported capable of running Linux using RISC-V instruction set.

We are presenting the implementation of a generator-based flexible data acquisition system implemented on FPGA with integrated Successive Approximation Register (SAR) ADCs and a 32-bit RISC-V softcore. Features of the system are: TileLink bus for interfacing between processor and the peripherals attached to it, a 16KiB instruction 2-way cache, 16KiB data SRAM, 8KiB read-only memory, Serial Peripheral Interface slave for output, dedicated Quad-SPI flash interface for holding code and data, UART for serial communication, General Purpose I/O (GPIO) complex, 16-bit Pulse Width Modulation (PWM) periphery, JTAG and debug unit with two hardware breakpoints and 12-bit SAR Analog-to-Digital converters. Most of the peripherals were written in hardware construction language (HCL) Chisel which is developed at UC Berkeley and it is based on Scala programming language. The design was implemented and tested on Xilinx Arty A7 FPGA.

II. The Rocket core

Data acquisition system was based around Rocket Chip SoC generator. The Rocket Chip is an open-source SoC design generator developed at UC Berkeley suitable for research and industrial purposes [6]. It generates general-purpose processor cores that use the open RISC-V ISA, and provides an in-order core generator. Instead of being a single instance of an SoC design, Rocket chip is highly parametrized and customized design generator that emits synthesizable Register Transfer Level (RTL) Verilog code. This extensive parametrization enables SoC designers to generate multiple SoCs from single high-level source thus enabling easy customization for specific application. For example, by changing few parameters a SoC designer can generate SoCs ranging from embedded microcontrollers to multi-core server chips. In order to provide generators for cores, caches, and interconnects, Rocket Chip is written in Chisel hardware construction language that supports advanced hardware design using highly parameterized generators and layered domain-specific hardware languages [7]. Chisel can generate a high-speed C++ based cycle-accurate software simulator, or low-level Verilog designed to map to either FPGAs or to a standard ASIC flow for synthesis.

Rocket chip deals with new modules by using Scala's object trait cake pattern which basically involves placing code inside traits. In the Rocket core there are two kinds of traits: a LazyModule trait and a module implementation trait. The LazyModule trait runs setup code that must execute before all the hardware gets elaborated. For a simple memory-mapped peripheral, this just involves connecting the peripheral's TileLink node to the Memory-Mapped I/O (MMIO) crossbar.

III. Architecture

In this work we are using the TileLink protocol developed by UC Berkeley for communication process. TileLink is a protocol designed to be a substrate for cache coherence transactions implementing a particular cache coherence policy within an on-chip memory hierarchy [8]. Its purpose is to orthogonalize the design of the on-chip network and the implementation of the cache controllers from the design of the coherence protocol itself. Any cache coherence protocol that conforms to TileLink's transaction structure can be used interchangeably with the physical networks and cache controllers from the Rocket Chip generator.

Used Rocket core supports local (including software and timer) interrupts and global interrupts. Local interrupts are signaled directly to an individual hart with a dedicated interrupt value which reduces interrupt latency as there is no arbitration required to determine which hart will service a given request, nor additional memory accesses required to determine the cause of the interrupt. Software and timer interrupts are local interrupts generated by the Core Local Interruptor (CLINT). Global interrupts are routed through a Platform Level Interrupt Controller (PLIC), which can direct interrupt to any hart in the system via the external interrupt.

The architecture of the microcontroller is shown in Fig. 1. All peripheral interfaces are interconnected to the TileLink bus. All peripherals are written as parametrized LazyModule and module implementation traits in order to enable easy integration with the Rocket core. Verilog code for Xilinx XADC IP is instantiated inside Chisel BlackBox module which is then connected to the TileLink bus by using TLRegisterRouter. TLRegisterRouter is used to abstracts away the details of handling the TileLink protocol and provides a convenient interface for specifying memory-mapped registers. The peripheral memory maps were designed to only require naturally aligned 32-bit memory accesses.

IV. Peripherals

In the this section the short overview of used peripherals is presented.

A. General Purpose I/O

The GPIO controller is a peripheral device mapped in the internal memory map. The GPIO complex manages the connection of digital I/O pads to digital peripherals, including SPI, UART, and PWM controller, as well as for regular programmed I/O operations. It is responsible for low-level configuration of the actual GPIO pads on the device (direction, pullup-enable, and drive value), as well as selecting between various sources of the controls for these signals. The GPIO controller allows separate configuration of each of *N* GPIO bits. GPIO module has parametrized number of GPIO bits and by changing the *width* parameter given bellow, different number of GPIO bits can be achieved.

```
case PeripheryGPIOKey=>List(
 GPIOParams(address=0x10012000,width=32))
```

B. Quad-SPI

A dedicated QSPI flash interface is provided to hold code and data for the system. The QSPI interface supports burst reads of 32 bytes over TileLink to accelerate instruction cache refills. The QSPI interface also supports single-word data reads over the primary TileLink interface, as well as programming operations using memory-mapped control registers.

The SPI controller supports master-only operation over the single-lane, dual-lane, and quad-lane protocols. The baseline controller provides a FIFO-based interface for performing programmed I/O. Software initiates a transfer by en-queuing a frame in the transmit FIFO; when the transfer completes, the slave response is placed in the receive FIFO. In addition, the dedicated QSPI_0 controller implements a SPI flash read sequencer, which exposes the external SPI flash contents as a read/execute-only memory-mapped device. The QSPI_0 controller is reset to a state which allows memory-mapped reads. QSPI_0 has Execute in Place mode enabled by default and one chip select signal. QSPI_1 has 4 chip select signals enabled.

In order to archive better performance, sequential accesses are automatically combined into one long read command. Switching between the programmed-I/O and memory-mapped modes is enabled by the *fctrl* control register. While in programmed-I/O mode, memory-mapped reads do not access the external SPI flash device and instead return 0 immediately. Hardware interlocks ensure that the current transfer completes before mode transitions and control register updates take effect.

Adding additional SPI to the system can be easily done just by adding new set of parameters inside PeripherySPIKey list. For example, in our data acquisition system we had QSPI_1 with four chip select signals at address 0x10024000. If we want to add another QSPI with only one chip select signal, we could write:

```
case PeripherySPIKey=>List(
 SPIParams(csWidth=4,rAddress=0x10024000),
 SPIParams(csWidth=1,rAddress=0x10034000))
```

By changing one line of code, new QSPI periphery with one chip select signal would be added at address 0x10034000.

C. UART

The UART peripheral supports the 8-N-1 and 8-N-2 formats: 8 data bits, no parity bit, 1 start bit, 1 or 2 stop bits. It supports 8-entry transmit and receive FIFO buffers with programmable watermark interrupts and 16×Rx oversampling with 2/3 majority voting per bit. Baud rate of the UART can be changed by changing the value of UART *div* register. Baud rate can be calculated as:

$$f_{baud} = \frac{f_{in}}{1 + div} \tag{1}$$

The UART peripheral does not support hardware flow control or other modem control signals, or synchronous serial data transfers.

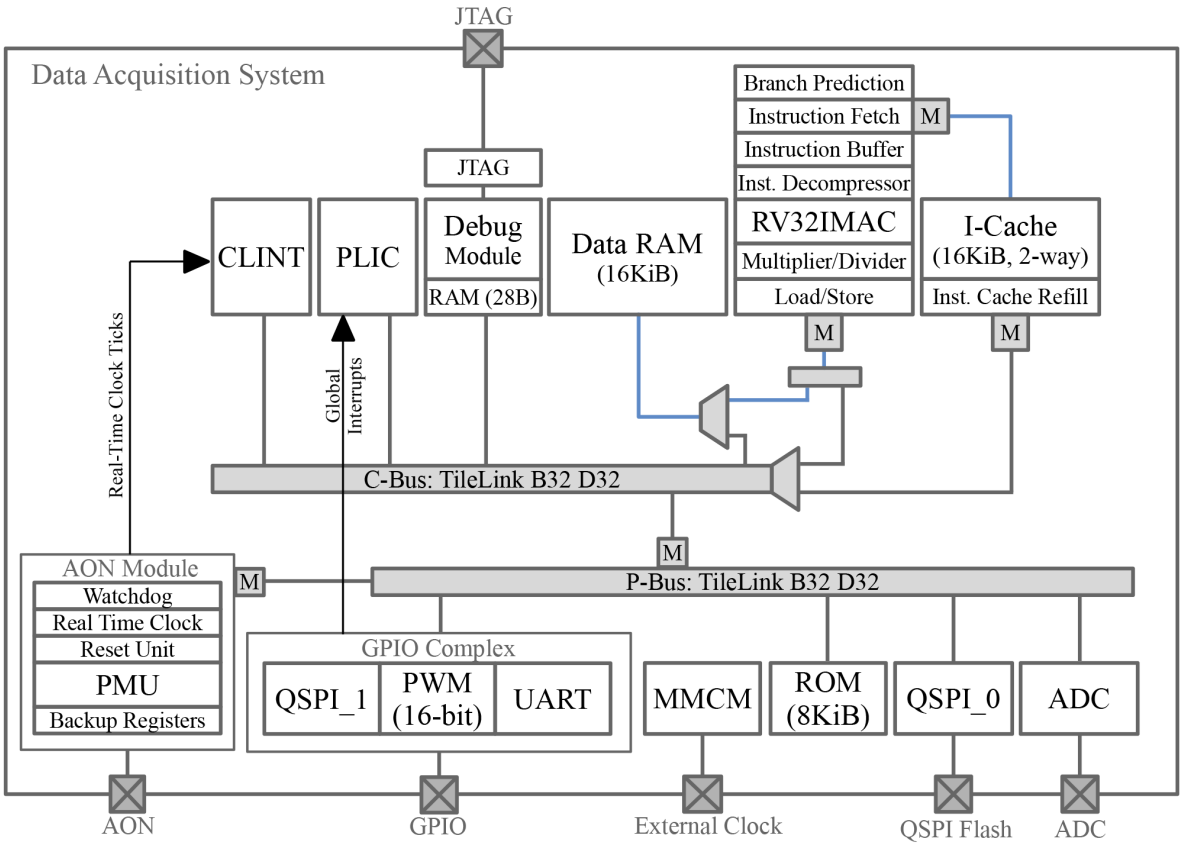

Fig. 1. Data acquisition system architecture.

Same as with SPI periphery, additional UART peripheries could be added by adding new set of parameters inside PeripheryUARTKey list:

```
case PeripheryUARTKey=>List(
 UARTParams(address=0x10013000),
 UARTParams(address=0x10023000))
```

D. PWM

The default PWM configuration contains four independent PWM comparators (*pwmcmp_0–pwmcmp_3*), but custom configurations with different number of comparators can be generated. The pulse width modulation (PWM) peripheral can generate multiple types of waveforms on GPIO output pins, and can also be used to generate several forms of internal timer interrupt.

The comparator results are captured in the *pwmcmp_X_ip* flops (where $X \in [0, 1, 2, 3]$) and then fed to the PLIC as potential interrupt sources. The *pwmcmp_X_ip* outputs are further processed by an output ganging stage before being fed to the GPIOs. The PWM unit can be provided in different comparator precisions up to 16 bits. In order to support clock scaling, the PWM count register is 15 bits wider than the comparator precision.

Different number of PWM peripherals can be added by adding new sets of parameters inside PeripheryPWMKey list. By changing the value of *cmpWidth* parameter, comparator precision can be set. For example, to set three different PWM modules with comparator precisions of 16, 12 and 8 bits respectively, PeripheryPWMKey list should contain:

```
case PeripheryPWMKey=>List(
 PWMParams(address=0x10015000,cmpWidth=16),
 PWMParams(address=0x10025000,cmpWidth=12),
 PWMParams(address=0x10035000,cmpWidth=8))
```

E. Always-on (AON) block

The AON block contains the reset logic for the chip, a watch-dog timer, connections for an off-chip low-frequency oscillator, the real-time clock, a programmable power-management unit, and 16×32-bit backup registers that retain their state while the rest of the chip is in a low-power mode. The AON can be instructed to put the system to sleep and the Always-on block can be programmed to exit sleep mode on a real-time clock interrupt or when the external digital wakeup pin is pulled low. An AON reset can be triggered by an external active-low reset pin or expiration of the watchdog timer. AON domain is continuously powered from an off-chip power source, either a regulated power supply or a battery.

F. Debug module

The debug module is accessed through JTAG, and has support for two programmable hardware break points. The

debug RAM has 28 bytes of storage. A JTAG connection is used to connect the external debugger to the internal debug module.

G. Analog-to-Digital converter

In order to perform analog to digital conversion, Arty A7 on-chip SAR Analog-to-Digital converters are used. The Xilinx IP XADC includes a dual 12-bit, 1 Megasample per second (MSPS) ADCs and on-chip sensors. The ADCs provides a general-purpose, high-precision analog interface for a range of applications. These ADCs support a range of operating modes, such as externally triggered and simultaneous sampling on both ADCs and various analog input signal types, for example, unipolar and differential. The ADCs can access up to 17 external analog input channels and also includes several on-chip sensors that support measurement of the on-chip power supply voltages and die temperature. The ADC conversion data is stored in dedicated registers called status registers. These registers are accessible through the FPGA interconnect using a 16-bit synchronous read and write port called the dynamic reconfiguration port (DRP). ADCs were used in continuous mode and four different external analog inputs were configured.

In order to connect Xilinx IP XADC to the TileLink, BlackBox wrapper for the Verilog ADC module is written. TLRegisterRouter and BlackBox ADC module were added to the module implementation trait, and the LazyModule trait was written for the ADC. By doing that, ADC module could be added to data acquisition system by extending our data acquisition class with ADC traits:

```
class dataAcquisitionSystem
  extends RocketSubsystem
    with HasPeripheryADCTL{
      override lazy val module
         = new dataAcquisitionModule(this)
    }

class dataAcquisitionModule
  [+L <: dataAcquisitionSystem](_outer: L)
  extends RocketSubsystemModuleImp(_outer)
    with HasPeripheryADCTLModuleImp
```

V. Results

The proposed data acquisition system was implemented on Xilinx Arty A7 FPGA. Mixed-Mode Clock Manager (MMCM) was used to generate 90MHz clock for Rocket core, 30MHz clock for JTAG and 10MHz clock for the AON module from the external 100MHz oscillator. Verification of the peripherals has been performed from the perspective of the Rocket core and the UART where UART was used for serial communication between FPGA and PC. The dedicated QSPI flash controller was used to fetch code from the off-chip SPI flash.

A simple C code was written to enable the ADC conversion and to send the sampled data via the UART. On the FPGA board, buttons were connected to the design and the interrupt routine was written for those buttons. By pressing the button, the ADC sampling flag was set. Inside the main loop 10k ADC samples were sent via the UART if ADC sampling flag was set. After sending sampled data, ADC sampling flag was unset. In order to send sampled data from the ADC with width of 16 bits, two UART transfers were needed considering UART symbol width of 8 bits. First 8 bits to be sent via UART were the upper 8 bits of the ADC data register and then the lower 8 bits were sent. Before sending ADC samples, 4 bytes used for data aligning were sent via UART and after sending ADC samples, two bytes were send to denote the end of UART transaction. Python script was written to collect data sent from microcontroller via UART and to plot received data.

In order to test functionality of the used integrated ADCs, signal generator was connected to the ADC input pins of the FPGA. Waveforms used for testing were sinusoidal, triangular and rectangular waveforms between 0V and 3V with frequencies 0.25kHz and 0.5kHz. Obtained diagrams for 0.25kHz waveforms are given in Fig. 2 and 0.5kHz waveforms are given in Fig. 3.

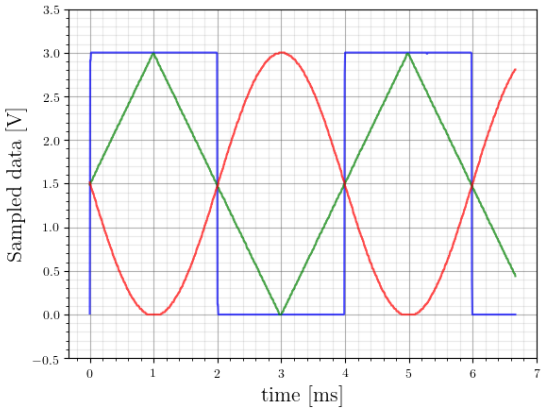

Fig. 2. Data sampled with waveform frequency of 0.25kHz.

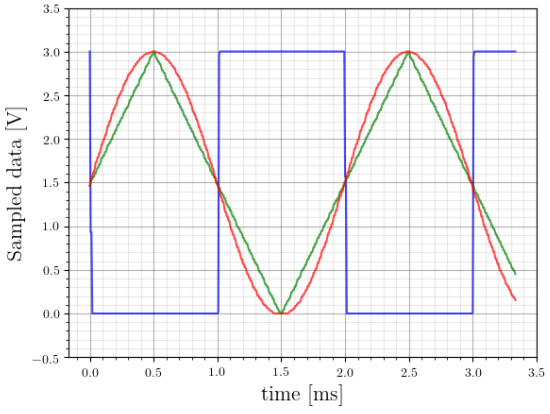

Fig. 3. Data sampled with waveform frequency of 0.5kHz.

In Table 1 post-implementation resource utilization is given and power estimation for the design is 0.308W where 42% is from MMCM.

TABLE I
POST-IMPLEMENTATION RESOURCE UTILIZATION

	Utilization	Available	Utilization %
LUT	14285	20800	68.7 %
LUTRAM	695	9600	7.24 %
FF	8159	41600	19.6 %
BRAM	5.5	50	11.0 %
DSP	2	90	2.23 %
MMCM	1	5	20.0 %

Layout of the implemented design on the Arty A7 FPGA board is presented in Fig. 4.

VI. CONCLUSIONS

In this work, a general purpose low-cost data acquisition system with integrated 12-bit SAR ADCs was presented and implemented on Xilinx Arty A7 FPGA. Data acquisition system was built around Rocket System-on-Chip design generator which is based on RISC-V ISA. By using extensive parametrization of the Rocket core and flexibility of peripherals written in Chisel hardware construction language, data acquisition system with extreme flexibility through comprehensive set of parameters was implemented and its operation as a low-end oscilloscope was demonstrated.

Stressing Issue of a Piezoceramic Cylinder with Radial Polarization

Igor Jovanović, Ljubiša Perić, Uglješa Jovanović and Dragan Mančić

***Abstract*—This paper presents a general case of stressing a circular-ring cross-sectional cylinder with a radial type of polarization. It is assumed that the cylinder is infinitely long in direction of the *z*-axis and that the componential strain in that direction is equal to zero.**

By applying the equations of electroelasticity in polar-cylindrical coordinates as well as satisfying electrical boundary conditions for the electric potential and mechanical boundary conditions for the mechanical stress of a cylinder with a radial type of polarization, componential displacements in radial direction are determined for the piezoceramic cylinder made from PZT4 piezoceramic material.

***Index Terms*—componential displacements, radial polarization, PZT4 piezoceramic materials.**

I. Introduction

Piezoceramics are one of the most common active materials used for ultrasonic transducers, actuators, resonators, wave filters delay lines, transformers, pressure sensing devices, energy harvesting devices, etc [1]. When used as piezoelectric actuators and sensors, their applications cover various fields of technology from the aerospace, military and industry, to instrumentation and medicine [2], [3].

Piezoelectric cylinders are basic actuating elements in various ultrasonic applications. The main subject of this study is investigation of free vibration of a circular-ring cross-sectional cylinder with a radial type of polarization. Knowing resonant frequencies of piezoelectric cylinders is an initial condition when designing sensors and transducers [4]. For the precise analysis of the oscillations of piezoelectric cylinders, it is ideal to use models that take into account the coupling between different oscillations (thickness, radial, flexion, etc.), which leads to a complex system of nonlinear equations that are difficult to solve [5].

In this paper, in general, the method of solving the problems of oscillating circular-ring cross-sectional cylinder with radial polarization and electrode coatings on cylindrical surfaces, on which an AC voltage is applied, is shown.

II. Fundamental Equations

At first, problem of radial polarization of hollow cylinder with electrode coatings on cylindric surfaces, shown in Fig. 1, is considered.

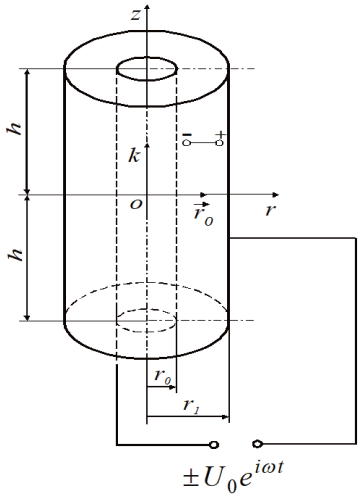

Fig. 1. Cylinder with radial polarization and electrodes on cylindric surfaces.

It is assumed that cylindrical surfaces of the annular cylinder $r=r_0$ and $r=r_1$ are completely covered with electrode coatings, on which electric voltage $\pm U_0 e^{i\omega t}$ is applied. So, oscillations of the cylinder are excited by alternate electric potential difference on electrodes, which is changing harmonically in time by circular frequency ω, obtained from electric voltage generator.

Electric boundary conditions, in case when electric voltage is applied onto the electrodes on cylindric surfaces, are [6]:

$$\psi\Big|_{r=\begin{Bmatrix} r=r_0 \\ r=r_1 \end{Bmatrix}} = \pm U_0 e^{i\omega t}, \tag{1}$$

$$D_z\Big|_{z=\pm h} = \left[-d_{11}^{\varepsilon} \frac{\partial \psi}{\partial z} + e_{15} \left(\frac{\partial u}{\partial z} + \frac{\partial w}{\partial r} \right) \right]\Bigg|_{z=\pm h} = 0, \tag{2}$$

This way of excitation of piezoceramic circular-ring cylinder causes occurrence of only radial oscillations, i.e., vector of componential displacements is $\vec{s} = u(r, t)\,\vec{r}_0$, and it has only radial component. Electric potential ψ is also function of only radial coordinate and time, that is $\psi=\psi(r,t)$. For this case of oscillations of kineto-electricity state parameters depend only of coordinate *r*, that is:

Igor Jovanović, Uglješa Jovanović and Dragan Mančić are with the University of Niš, Faculty of Electronic Engineering, 14 Aleksandra Medvedeva, 18000 Niš, Serbia (e-mail: igor.jovanovic@elfak.ni.ac.rs, ugljesa.jovanovic@elfak.ni.ac.rs and dragan.mancic@elfak.ni.ac.rs).

Ljubiša Perić is with the Regional Chamber of Economy Niš, Dobrička 2, 18000 Niš, Serbia (e-mail: ljubisa.peric@rpknis.rs).

$$u = u(r,\ t),$$
$$\psi = \psi(r,\ t), \qquad (3)$$
$$v = 0,\ \ w = 0,$$

By substituting coordinates (3) into Cauchy's kinematic equations:

$$\varepsilon_r = \frac{\partial u}{\partial r},\ \ \gamma_{rz} = 2\varepsilon_{rz} = \left(\frac{\partial u}{\partial z} + \frac{\partial w}{\partial r}\right),$$
$$\varepsilon_\phi = \frac{1}{r}\frac{\partial v}{\partial r} + \frac{u}{r},\ \ \gamma_{r\phi} = 2\varepsilon_{r\phi} = \left(\frac{\partial v}{\partial r} - \frac{v}{r} + \frac{1}{r}\frac{\partial u}{\partial \phi}\right), \qquad (4)$$
$$\varepsilon_z = \frac{\partial w}{\partial z},\ \ \gamma_{z\varphi} = 2\varepsilon_{z\varphi} = \left(\frac{\partial v}{\partial z} + \frac{1}{r}\frac{\partial w}{\partial \varphi}\right).$$

and into the equations of electroelasticity [7]:

$$\vec{E} = -grad\psi, \qquad (5)$$

one gets:

$$\varepsilon_r = \frac{\partial u}{\partial r},\ \ \varepsilon_\phi = \frac{u}{r},\ \ E_r = -\frac{\partial \psi}{\partial r},$$
$$E_r = -\frac{\partial \psi}{\partial r},\ E_r = E_\varphi = 0 \qquad (6)$$
$$\varepsilon_z = 0,\ \ \gamma_{\phi z} = \gamma_{rz} = \gamma_{r\phi} = 0.$$

In deriving of the coupled equations of electroelasticity for piezoceramic cylinders with radial polarization, one must start from equations of piezoelectric effect:

$$\sigma_r = c_{33}^E\varepsilon_r + c_{13}^E\left(\varepsilon_\phi + \varepsilon_z\right) - e_{33}E_r,$$
$$\sigma_\phi = c_{13}^E\varepsilon_r + c_{11}^E\varepsilon_\phi + c_{12}^E\varepsilon_\phi - e_{31}E_r,$$
$$\sigma_z = c_{13}^E\varepsilon_r + c_{12}^E\varepsilon_\phi + c_{11}^E\varepsilon_z - e_{31}E_r,$$
$$\tau_{r\phi} = c_{44}^E\gamma_{r\phi} - e_{15}E_\phi,$$
$$\tau_{rz} = c_{44}^E\gamma_{rz} - e_{15}E_z, \qquad (7)$$
$$\tau_{\phi z} = \frac{1}{2}\left(c_{11}^E - c_{12}^E\right)\gamma_{\phi z},$$
$$D_r = d_{33}^\varepsilon E_r + e_{31}\left(\varepsilon_\phi + \varepsilon_z\right) + e_{33}\varepsilon_r,$$
$$D_\phi = d_{11}^\varepsilon E_\phi + e_{15}\gamma_{r\phi},$$
$$D_z = d_{11}^\varepsilon E_z + e_{15}\gamma_{rz}.$$

By inserting the obtained expressions (6) into the state equations for radial type of cylinder polarization (7), one gets expressions for componential mechanical stresses (σ) and piezoelectric displacements (D):

$$\sigma_r = c_{33}^E\frac{\partial u}{\partial r} + c_{13}^E\frac{u}{r} + e_{33}\frac{\partial \psi}{\partial r},$$
$$\sigma_\phi = c_{13}^E\frac{\partial u}{\partial r} + c_{11}^E\frac{u}{r} + e_{31}\frac{\partial \psi}{\partial r},$$
$$\sigma_z = c_{13}^E\frac{\partial u}{\partial r} + c_{12}^E\frac{u}{r} + e_{31}\frac{\partial \psi}{\partial r}, \qquad (8)$$
$$D_r = -d_{33}^\varepsilon\frac{\partial \psi}{\partial r} + e_{31}\frac{u}{r} + e_{33}\frac{\partial u}{\partial r},$$
$$\tau_{\phi z} = \tau_{rz} = \tau_{r\phi} = 0,$$
$$D_\phi = D_z = 0.$$

By substituting expression (8) into Navier's equations of motion:

$$\frac{\partial \sigma_r}{\partial r} + \frac{1}{r}\frac{\partial \tau_{r\phi}}{\partial \phi} + \frac{\partial \tau_{rz}}{\partial z} + \frac{\sigma_r - \sigma_\phi}{r} = \rho\frac{\partial^2 u}{\partial t^2},$$
$$\frac{\partial \tau_{r\phi}}{\partial r} + \frac{1}{r}\frac{\partial \sigma_\phi}{\partial \phi} + \frac{\partial \tau_{z\phi}}{\partial z} + \frac{2\tau_{r\phi}}{r} = \rho\frac{\partial^2 v}{\partial t^2}, \qquad (9)$$
$$\frac{\partial \tau_{rz}}{\partial r} + \frac{1}{r}\frac{\partial \tau_{z\phi}}{\partial \phi}\frac{\partial \sigma_z}{\partial z} + \frac{2\tau_{rz}}{r} = \rho\frac{\partial^2 w}{\partial t^2},$$

and into the equation of electroelasticity [7]:

$$\vec{E} = -\frac{\partial \psi}{\partial r}\vec{r}_0 - \frac{1}{r}\frac{\partial \psi}{\partial \phi}\vec{c}_0 - \frac{\partial \psi}{\partial z}\vec{k}, \qquad (10)$$

one gets system of two partial differential equations in form of [6]:

$$c_{33}^E\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial u}{\partial r}\right) - \frac{c_{11}^E}{r^2}u = \rho\frac{\partial^2 u}{\partial t^2} - e_{33}\frac{\partial^2 \psi}{\partial r^2} - \frac{e_{33} - e_{31}}{r}\frac{\partial \psi}{\partial r}, \qquad (11)$$
$$d_{33}^\varepsilon\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial \psi}{\partial r}\right) = e_{33}\frac{\partial^2 u}{\partial r^2} + \frac{e_{33} + e_{31}}{r}\frac{\partial u}{\partial r}. \qquad (12)$$

Further, it is assumed that on cylindric surfaces $r=r_0$ and $r=r_1$ external mechanical loads are absent, so the general expression for the vector of total stress on contour surfaces is equal to zero. Conditions for absence of shear stresses are identically satisfied because of absence of displacements v and w, and condition for absence of normal stress σ_r leads to the following equation (mechanical boundary conditions):

$$\sigma_r\Big|_{r=\begin{Bmatrix} r_0 \\ r_1 \end{Bmatrix}} = \left(c_{33}^E\frac{\partial u}{\partial r} + c_{13}^E\frac{u}{r} + e_{33}\frac{\partial \psi}{\partial r}\right)\Bigg|_{r=\begin{Bmatrix} r_0 \\ r_1 \end{Bmatrix}} = 0. \qquad (13)$$

Solutions of partial differential equations (11) and (12) are searched for in the following form:

$$u\left(r,\ t\right) = \hat{u}\left(r\right)e^{i\omega t}, \qquad (14)$$

$$\psi(r,t)=\hat{\psi}(r)\,e^{i\omega t}. \tag{15}$$

By substituting assumed solutions (14) and (15) into the system of differential equations (11) and (12), one gets the following system of common differential equations for determination of amplitude eigenfunctions:

$$c_{33}^{E}\frac{1}{r}\frac{d}{dr}\left(r\frac{d\hat{u}}{dr}\right)-\frac{c_{11}^{E}}{r^2}\hat{u}+\rho\omega^2\hat{u}=-e_{33}\frac{d^2\hat{\psi}}{dr^2}-\frac{e_{33}-e_{31}}{r}\frac{d\hat{\psi}}{dr}, \tag{16}$$

$$d_{33}^{\varepsilon}\frac{1}{r}\frac{d}{dr}\left(r\frac{d\hat{\psi}}{dr}\right)=e_{33}\frac{d^2\hat{u}}{dr^2}+\frac{e_{33}+e_{31}}{r}\frac{d\hat{u}}{dr}. \tag{17}$$

The equation (17) is integrated with respect to r, and as a result one gets:

$$d_{33}^{\varepsilon}\frac{d\hat{\psi}}{dr}=e_{33}\frac{d\hat{u}}{dr}+e_{31}\frac{\hat{u}}{r}+\frac{C}{r},$$

$$\int r\frac{d^2\hat{u}}{dr^2}\,dr=r\frac{d\hat{u}}{dr}-\hat{u}, \tag{18}$$

$$\frac{d^2\hat{\psi}}{dr^2}=\frac{e_{33}}{d_{33}^{\varepsilon}}\frac{d^2\hat{u}}{dr^2}-\frac{e_{31}}{d_{33}^{\varepsilon}}\frac{\hat{u}}{r^2}+\frac{e_{31}}{d_{33}^{\varepsilon}}\frac{1}{r}\frac{d\hat{u}}{dr}-\frac{C}{d_{33}^{\varepsilon}}\frac{1}{r^2},$$

where C is an arbitrary constant.

Now the expression (18) is substituted in the equation (16), amplitude eigenfunction of the electric potential $\hat{\psi}$ is excluded, and one gets:

$$r^2\frac{d^2\hat{u}}{dr^2}+r\frac{d\hat{u}}{dr}+\left(\lambda^2r^2-\nu_1^2\right)\hat{u}=\frac{e_{31}C}{c_{33}^{E}d_{33}^{\varepsilon}+e_{33}^2}, \tag{19}$$

standard form of differential equation of the second order, for amplitude eigenfunction of the componential displacement $\hat{u}(r)$, which contains on the right side an addend with arbitrary constant C.

Characteristic numbers λ and ν_1 are determined according to expressions:

$$\lambda=\omega\sqrt{\frac{\rho\,d_{33}^{\varepsilon}}{c_{33}^{E}\,d_{33}^{\varepsilon}+e_{33}^2}},\quad \nu_1=\sqrt{\frac{c_{11}^{E}d_{33}^{\varepsilon}+e_{31}^2}{c_{33}^{E}d_{33}^{\varepsilon}+e_{33}^2}}. \tag{20}$$

General solution of the common differential equation (19) can be expressed through Bessel's functions of first and second rank of J_ν and Y_ν real argument, that is:

$$\hat{u}(r)=AJ_\nu(\lambda r)+BY_\nu(\lambda r)+\frac{\pi}{2}\frac{e_{31}C}{c_{33}^{E}d_{33}^{\varepsilon}+e_{33}^2}\cdot$$

$$\cdot\left\{Y_\nu(\lambda r)\int_{r_0}^{r}J_\nu(\lambda r)\frac{dr}{r}+J_\nu(\lambda r)\int_{r}^{r_1}Y_\nu(\lambda r)\frac{dr}{r}\right\}, \tag{21}$$

one may see that new arbitrary constants A and B are introduced. By introducing the solution (21) into the first equation (18) and integrating, one gets an expression for amplitude eigenfunction of the electric potential:

$$\hat{\psi}(r)=\frac{e_{33}}{d_{33}^{\varepsilon}}\left[\hat{u}(r)-\hat{u}(r_0)\right]+\frac{C}{d_{33}^{\varepsilon}}\ln r+\frac{e_{31}}{d_{33}^{\varepsilon}}\int_{r_0}^{r}\hat{u}(r)\frac{dr}{r}+C_1. \tag{22}$$

In the obtained expressions for amplitude eigenfunction $\hat{u}(r)$ and $\hat{\psi}(r)$ one may see that four arbitrary constants exist. They are determined from the condition of satisfying electric and mechanical boundary conditions on the surfaces of the piezoceramic annular specimen (1) and (13). By introducing the expression (21) and (22) into mentioned boundary conditions one gets system of four algebraic equations with four unknowns – A, B, C, and C_1, which are very complex.

III. Numerical Analysis and Discussion

Subject of observation in this paper is stressing of circular-ring cross-sectional PZT4 [8] cylinder with a circular type of polarization, with the following dimensions: r_0=7.5 mm, r_1=19 mm and density ρ=7500 kg/m^3 (Fig. 1).

Numerical analysis was performed using Matlab software, and radial displacement distributions of the points between cylindrical surfaces of piezoceramic cylinder were obtained for the first and the second radial resonant modes.

Figures 2 and 3 present radial displacements of points between the inner and outer cylindrical contour surfaces in the function of radius, r, and frequency, f. One may notice that in case of both modes, internal and external cylindrical surfaces move in the same directions (Fig. 2 and Fig. 3), while for the second mode (Fig. 3), the cylinder acts as a full-wave resonator. This means that for this case at r=10.37 mm and r=16.13 mm exists a circular line that represents the wave node, for which the displacement is u_r=0.

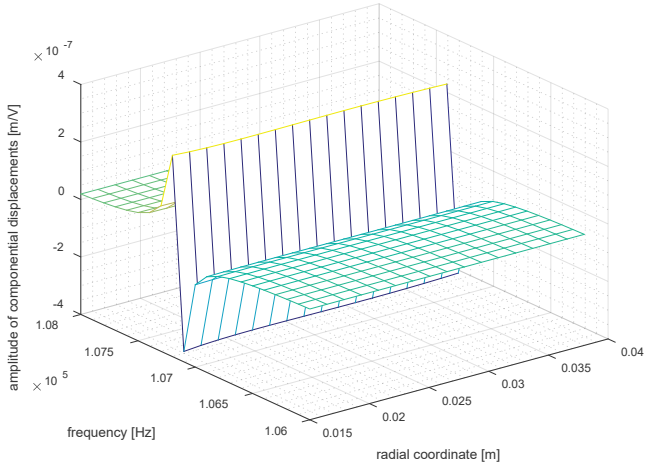

Fig. 2. Amplitude of componential displacement $u(r,f)$ in the vicinity of the first resonant mode

With the proposed method it is possible to perform a

dependence analysis of the amplitude of componential displacement on the ratio of the inner and outer radius, and in this way to predict the behavior of the cylinder of known piezoceramic characteristics at certain frequencies prior to production. Based on this, it is possible to optimize the dimensions of the piezoceramic cylinder (Fig. 4).

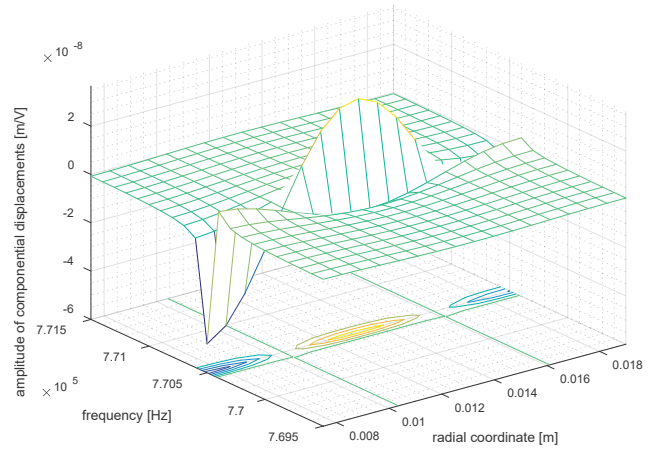

Fig. 3. Amplitude of componential displacement $u(r,f)$ in the vicinity of the second resonant mode

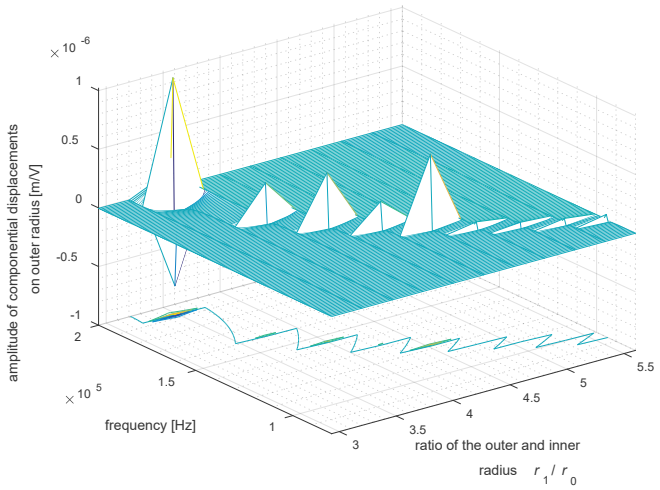

Fig. 4. Theoretical relationship between the amplitude of componential displacement on outer radius $u(r_1,f)$ and the ratio of the outer and inner radius r_1/r_0 for first resonant mode.

Fig. 4 shows that the optimal ratio of the external and internal radius is r_1/r_0=3.467, and the maximum amplitude of componential displacement are obtained for the external radius r_0=26 mm, for the given inner radius r_0=7.5 mm. In this case, the maximum amplitude of the componential displacement on the outer radius is 1.02 μm/V at the frequency of 193 kHz.

Fig. 4 also shows the influence of cylinder dimensions on the first resonant mode. The higher the radial dimensions of the cylinder, the first resonant mode slides to lower frequencies.

IV. Conclusion

In addition to the existence of the unknown coefficients A, B, C, and C_1 in (21) and (22), algebraic equations also include Bessel's functions of fractional index and their integrals, which are expressed by Lamé's functions. However, calculation using Matlab software significantly extenuate this problem.

This paper presents a method of studying elastic wave propagation in circular-ring piezoceramic cylinder with a radial type of polarization. When electric voltage is applied to the observed cylinder, two resonant modes occur at frequencies up to 800 kHz, at the following frequencies: 107.1 kHz and 770.5 kHz. In the second mode, the cylinder acts as a full-wave resonator (Fig. 3). It is also justified movement of radial resonant modes to lower frequencies in the case of an increase in the radial dimensions of the cylinder (Fig. 4).

Measurement of displacement of the cylinder will be the subject of further research.

Improving the Production Efficiency by Using the InfinityQS - a Real-time SPC Software

Miljana Milić, Zoran Milić, and Alex Crittenden

***Abstract*—Statistical process control (SPC) is a method of production process quality control which employs statistical calculations to monitor the manufacturing process, and keep it under control. InfinityQS is a software solution which enables implementation of a real-time SPC. The idea is to collect a real-time data from sensors and statistically process it in order to obtain a real-time image of the process stability and quality. This software is specialized in this field allowing for and easy data connectivity, and a real-time reporting/charting. Among numerous features, the most useful are basic SPC control charts. Control limits, specification limits, target values, mean values, and process capability indicators are measured/calculated and displayed on the control chart. This allows for a very effective visual recognition of situations where process is out of control, and immediate detection and action can be initiated to maintain the quality and minimize the scrap. The software also facilitates other actions which will eliminate special i.e. systematic causes of variations in parameters of the process, and make it stable and predictive, i.e. under control.**

***Index Terms*—Statistical process control; reliability; sensor networks; production lines.**

I. Introduction

Improving the quality of a product is the deciding aspect of any production or service, and it leads to enhancement, growth, and success in business and consequently better competitiveness [1]. The quality of a product is one of the most important factors that a consumer (regardless of whether it is an individua, an industry or etc.) takes into consideration when choosing among many competing products and services. The return on investment is more certain when high quality of the product is considered as the targeting production parameter in any planning of business [1].

To quantify the amount of quality of a certain product, one has to answer the following questions, and determine the level of corresponding issues:

- Will the product perform specific functions and how well it performs them? - Product performance,
- How often does the product fail when operating under a stated operating condition? – Product reliability,
- How long is the service life of the product? – Product durability,
- How difficult and financially affordable are maintenance and repair procedures for the product? – Product serviceability,
- How attractive is the visual appeal of the product? Product aesthetics,
- What are the features added to the basic performance of the product? – Product added features,
- What is the past reputation of the company concerning quality of their products? – Perceived quality of the product
- How exactly does the manufactured product parts meet the customer's/designer's requirements? – Product's conformance to Standards [2].

In order to fulfil the quality standards of the product or a production [2], [3] and achieve high reputation among customers, it is highly recomended to implement a specific control over the production process on the plant floor. Statistical process control (SPC) is defined as a group of software tools that use statistical measures to maintain the stability of the product manufacturing process, improve its capabilities, and minimize process variabilities [4].

The implementation of the SPC is highly corelated and dependent on the parameters of the manufacturing process, obtained i.e. measured from sensor networks. Sensors for this purpose represent sensing and measuring devices which can communicate through the network and whose activities can be controlled, since these nodes may have limited capacities [5]. Process measurements are obtained in real-time during manufacturing. If the right kinds of data are being collected from the right points of the production lines, it is easier to determine the cause of quality issues [6]. Sensing devices should be positioned in a way to enable maximal information extraction from the field. Collected data are later analysed and often support decision-making at the higher-level of management [5].

This paper describes some basic features and benefits of a particular SPC environment implementation. The InfinityQS represents a leading SPC solutions applied by a number of leading corporations. Some basic definitions and equations from the theory of the SPC will be given next. Then, some possibilities and features of the InfinityQS will be listed. A practical case study implementation of the InfinityQS for the particular production line will be shown at the end, as well as some concluding remarks.

II. About Statistical Process Control

There is a very limited amount of variations in the process that mass-production can tolerate. When variations do not exceed certain limits, it is sad that the manufacturing process is under control in each of its phases. In general, there are five groups of causes of unwanted variations that can be identified in the process. They are: raw materials, equipment, human actions, environment conditions, and methodology [7]. Variations are categorized in two groups:

- usual – tolerable variations, which are normal in the mass-production and have random nature, but are predictable, and
- specific – unwanted variation, whose causes are beyond the usual random changes of the process parameters, and cannot be predicted.

The key task of the SPC is to determine the cause of the specific process variations, by monitoring all relevant process parameters in time. Statistically predictable and tolerable variation do not require any actions, but for processes with some specific causes of variations, some actions need to be conducted to diminish them and they should be defined with a production Control plan [8].

With a SPC, process measurements' data obtained during manufacturing is then plotted in real-time on a graph referred to as a Control chart. Each process as well as the chart has two types of pre-defined limits: control limits are determined by the capability of the process (Voice of a process – VOP), and specification limits that are defined by the client (Voice of a customer – VOC). The parameter distribution as well as the corresponding limits are shown in Fig. 1. It should be emphasized that the VOC and the VOP are independent.

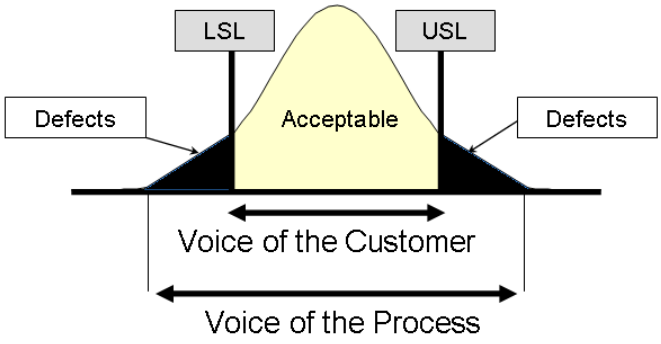

Fig. 1. Types of process limits.

When a process forms a stable distribution over time it is said to be under control. These distributions express the VOP. Process capability on the other hand expresses the goodness of a process, and is strongly related to customer specifications. These specification ranges i.e. the tolerances express the VOC here. This is illustrated in Fig. 2 [9].

Besides the usual statistical measures of the statistical process, such as the mean μ of the parameter and its standard deviation σ, some additional indicators need to be defined in order to implement SPC. They are: Cp - Process Capability, Cpk - Process Capability Index, Pp - Process Performance, and Ppk - Process Performance Index. Each of them will be defined and briefly explained next.

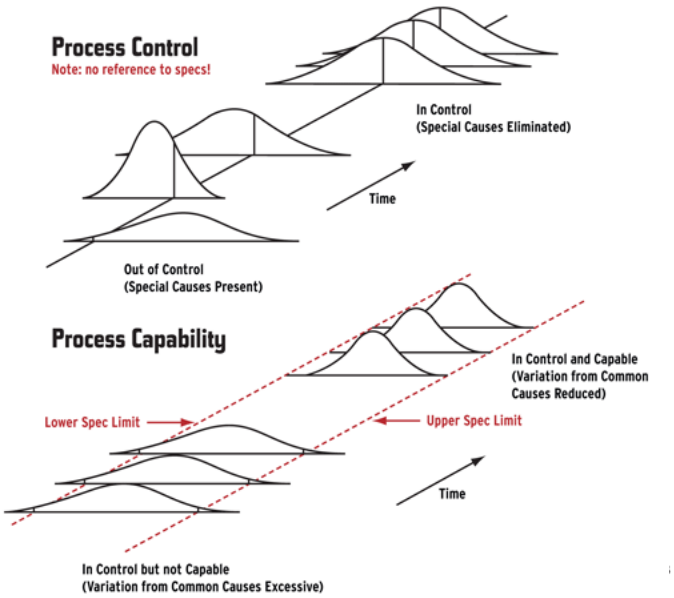

Fig. 2. Process control versus process capability.

Process capability can be calculated using as in (1):

$$Cp = \frac{USL\text{-}LSL}{6\sigma} \tag{1}$$

where USL and LSL represent upper and lower specification limits, respectively [1], while σ stands for the standard deviation of observed process parameter. It is the measure of how well the process meets customer specifications. At the other hand Process capability index Cpk, takes into consideration process centring and is calculated using (2):

$$Cpk = \min(Cpu, Cpl) = \min\left(\frac{USL\text{-}\mu}{3\sigma}, \frac{\mu\text{-}LSL}{3\sigma}\right). \tag{2}$$

In the simplified explanation, Cpk represents the one-sided Cp for the specification limit nearest to the process average μ [1]. Process Performance Pp, and Process Performance Index Ppk, can be calculated using the same equations (1), and (2), respectively. Differences between these two groups of measures are as follows. Process Capability indices Cp, and Cpk are calculated on samples; they are short term indices, and describe how well the process will perform in the future. At the other hand, Process performance indices Pp, and Ppk are calculated on the population; they are long term indices, and define how well the process has performed in the past. If the process is in statistical control, Cpk and Ppk are essentially the same [10].

Control charts are the basic graphical representation of the process quality that enable displaying and predicting of the process performances. By using them one can simply identify the existence of special causes of variations. With an SPC, control charts are used to provide information about weather a process is in statistical control or out of it, which is

determined by the nature of the process variations, as stated earlier in the text. One example of a control chart is shown in Fig. 3 [11]. The x axis represents the time, while the y axis represents the observed parameter values. Components of the control chart are the following lines: USL and LSL, target value of the parameter, average value, upper (+3σ) and lower (-3σ) control limits. Some areas of the control chart are also important to monitor. They are: a region of the expected variations - placed between upper and lower control limits, and a region of the unwanted variations – placed out of the control limits. Usually, the statistical control limits are set to +/- 3σ. In such cases, 99.73% of the charted variable fall within those limits. When a point appears outside of the control limits of the control chart, this should be alarmed, and an operator should perform actions defined by the Control plan or the plan of the reactions.

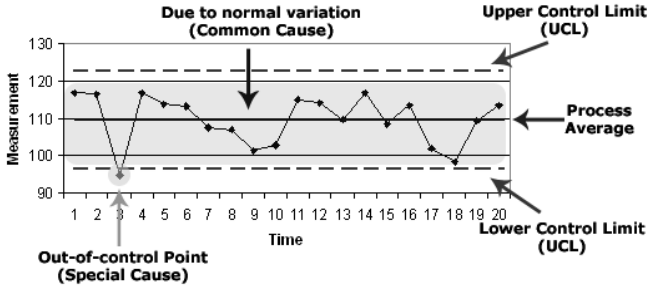

Fig. 3. The control chart.

In order to keep the process under control it is necessary to fulfil the following: the mean of the observed parameter should be as close as possible to the target value, and the Ppk should be greater than 1.3.

One implementation of a SPC using the InfinityQS solution for a simple example of the manufacturing process will be given next.

III. Implementing the InfinityQS on a Simple Production Process

ProFicient is the most important application of the InfinityQS solution that provides a customizable data-collection interface that supports multiple types of data input, manual and automatic [12]. Different charts are available for detailed insight into both real-time data, and historical trends of the process: control charts, Pareto charts, Cpk reports, box & whisker plots, capability analysis, scatter plots, trend charts, SPC monitor, etc. It enables detection of the cause codes, and corrective action codes, to quickly identify and prioritize the potential issues. There are also some very useful traceability features, such as lot genealogy, descriptors and serial numbers.

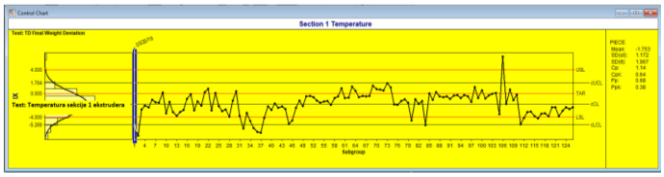

Fig. 4. The InfinityQS Xbar and Range control chart.

A case study of the simplified example of a part of the manufacturing process will be given next. The studied production system part is a line for extrusion of plastic. The extrusion is often part of the mass-production process. The plastic material is melted with the application of heat and extruded through a die into a desired shape. A cylindrical rotating screw is placed inside the barrel which forces out molten plastic material through the die. The extruded material takes shape according to the cross-section of the die. There are five important process parameters to be monitored during the extrusion process using a network of sensors: melting temperature of plastic, speed of the screw, the extrusion pressure, shape of the material that exits the die, and the cooling mechanism.

The Xbar and range control charts for the width of the extruded material is shown in Fig. 4. The Xbar gives the real-time histogram of the material width variations, while the Range control chart displays width variation trend with the respect to USL and LSL, and a target value.

A process under control for the described extrusion of plastic, monitored with the InfinityQS control chart is shown in Fig. 4. The parameter that is observed is the temperature of the melting plastic.

If the process exceeds some of the limits, the chart alarms it with the change of the color, and turns red. This is shown in Fig. 5. In this figure, an alarm for high temperature of the plastic is activated.

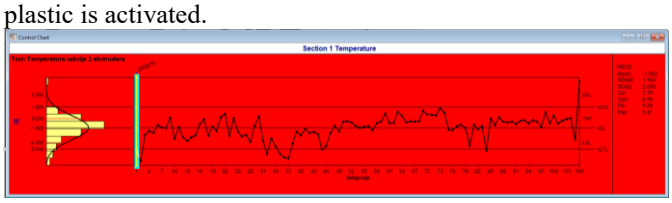

Fig. 5. Alarming an issue with the InfinityQS – process is out of control (high melting temperature of plastic).

In this case, the machine operator will easily notice the color change of the control chart at the machine Control panel. The corresponding extrusion section of the plastic should then be discarded as scrap, or will be properly marked for later disposal.

Also, the operator should then inform the subject matter expert about the event, who will analyze the occurrence of the event and perform steps in order to eliminate its causes.

Control charts are well known in mass production. But the obtained data are either manually entered, or the analysis are being performed on the historical data. The described software solution enables the real-time display of the quality parameters for the particular manufacturing process. With it, an operator at the machine (instead of a specialist) can easily and timely detect different quality issues, and the situations when the process is out of specified tolerances and control. The timed reaction of the operator significantly improves the process quality and reduces scrap.

IV. Conclusion

In this paper, one highly reputable, commercial SPC solution have been presented. It is greatly recemented in the mass-production for implementing the production quality

standards on the plant floor. The most important benefits of the ProFicient as the most important application of the InfinityQS SPC solutions are: significant reduction of the process variability and scrap, significant reduction of the production expenditures, scientific improvement of the process productivity, instant alarming and reactions to unwanted process variations, enabling the corresponding real-time decisions at the plant floor. The software also enables improved data collection from the network sensors, their analysis, processing, reports, storage, in order to compare qualities across multiple products, production lines and production sites. The complex analysis of data can be performed in real-time or using historical data within one chart or report.

Sensor node architecture for network control applications

Ivan Popović, Aleksandar Rakić, *Member, IEEE,*
Wenjun Zhang, Minrui Fei, Chen Peng and Dajun Du

***Abstract* – A novel architecture for sensor nodes is presented for specific application in networked control systems, where basic sensing and data acquisition functionalities are tied to several other and equally important functionalities regarding time-related services and middleware support for data transfer over the network. The main benefits of the proposed service-oriented architecture can be found in the domain of simplified design of the sensor node as well as its integration within the networked control systems.**

Key words: Network control systems; sensor node architecture; time-aware processing; service-oriented

I. Introduction

Growing interest in applying Internet of Thing (IoT) technologies in the field of Industry 4.0, smart cities, smart grid and connected infrastructures is derived from intensive deployment of Wireless Sensor Networks (WSN) in last decades. The extensive development of WSN is supported through the technology advances in the area of computer networking and communication. More generally, these advances enable integration of various end-devices in complex distributed systems and applications. One class of distributed systems are Network Control Systems (NCS), where process control loop is closed through the communication network. Regarding the design of NCS there are several, system operation and implementation related challenges that give rise to many important research topics. NCS architecture, process control algorithms, model of system components' implementation, information security, communication protocols and data formats, reliability of system operation, resilience to network communication problems, fault detection and monitoring, are some of the related topics studied in depth [1-5]. However, implementation of NCS sensing functionality according to the unified service-oriented model was not addressed in particular.

Adoption of service-oriented architecture (SOA) [6-9] and agents [10-14] in the industrial control system design is recognized as a promising opportunity to integrate the network capable heterogeneous devices and systems. The network environment enables dislocation of the key control system elements, i.e. sensors, actuators and control algorithms, to the separate network nodes. Additionally, smart transducer concept, defined through the IEEE 1451 family of standards, provides solution for service-oriented implementation of sensor and actuator components.

The family of standards is imposed in the form of upgrade of the basic IEEE 1451.0 services and functionalities [15], providing support for SOA concept. SOA is implemented using the Web service technology, as it uses SOAP/XML message format and standard protocols such as HTTP. Although SOA can be implemented in a different, application specific way [16-20], SOAP/XML Web services are preferred implementation solution as it does not conflict with firewalls and HTTP proxies. In [21], Web services are defined to reflect the IEEE 1451.0 smart transducer operations leading to concept known as Smart Transducer Web Services (STWS).

Although IEEE 1451 together with service-oriented architectural style defines framework for the implementation of basic sensing functionality, we are looking for other top-level architectural assets found in NCS operation.

Toward the goal design engineers need to understand and analyze the typical application properties given in the form of the context and context-aware behavior related to the NCS execution. An understanding of how context can be used will help the design engineers to agree-on what context-aware behavior is to be supported at the different levels of the system architecture. In the past various categorizations of the common application context properties were proposed. Nevertheless, the time property is found to be one of the most important application contexts, resulting in the time-aware model of the information processing. From the NCS point of view, time-awareness or time-sensitivity defines the critical aspect for the reliable execution of the data acquisition, processing, communication and control operation. Regarding the operation of sensors and actuators, time property is related to the continuous sampling functionality, while the time-aware controller operation is addressed in the domain of the control theory.

On the other hand, time related communication properties, introduced in the networked environment, such as varying network latency, packet losses are influencing the overall NCS operation. Therefore, special attention needs to be paid

to the design of the middleware as the middle-layer in the software architecture that enables communication and data management in the networked environment. The middleware provides common programming abstraction and infrastructure for the integration of different heterogeneous computing and communication devices. Since in the case of the NCS all system components share the common temporal property, as a model for the middleware implementation, we selected the time-aware approach. As a result, we take on the service-oriented concept as a uniform framework for the implementation of the process control and transducer nodes in the form of a group of network accessible services. On the other hand, the automated data transport is managed by a collection of service agents as configurable middleware components as shown in [22,23]. Thus, sensor node operation integrates basic sampling functionality, but also the group of middleware-related and time-related services. Therefore, these properties are supported through an introduced top-level component-based architectural style.

The immediate benefits of the proposed architecture are:

- layered hierarchy enables seamless integration of system application-layer components, service collaboration, implementation of security and discovery procedures and physical migration of services by the introduced service access layer,
- regarding data access model, architecture supports both passive sensor operation, where sensor node acts a data server, and active sensor operation, where sensor node acts as a configurable data publisher,
- the architecture itself it agnostic to physical deployment of system components, network topology and utilized application/transport layer communication protocols, and specific data acquisition and processing requirements.

The following sections of the paper give the overview of the corresponding sensor node architecture appropriate for network control applications and details regarding the sensor node operation, respectively.

II. Sensor Node Architecture

The proposed sensor node architecture is presented on Fig. 1. The architecture supports identified, NCS-specific, and traditional sensor side operations in the form of network accessible services, as configurable system components. Sensor node architecture assumes that each physical network node can contain single or a group of system components.

At the application (e.g. process) layer, standard sensor operations regarding A/D conversion, sampling control, raw sensor data processing, cross-correction, data aggregation, etc. are supported. These operations are specific to particular sensor type, its operation principle, application-level requirements and hardware platform. On the other hand, application-related processing regarding data protection, communication security, data storage, sensor node deployment and discovery, system integration, etc., is given in the form of collaborative execution utilizing services from other architectural layers. Service access is governed through service manager component at the service access layer.

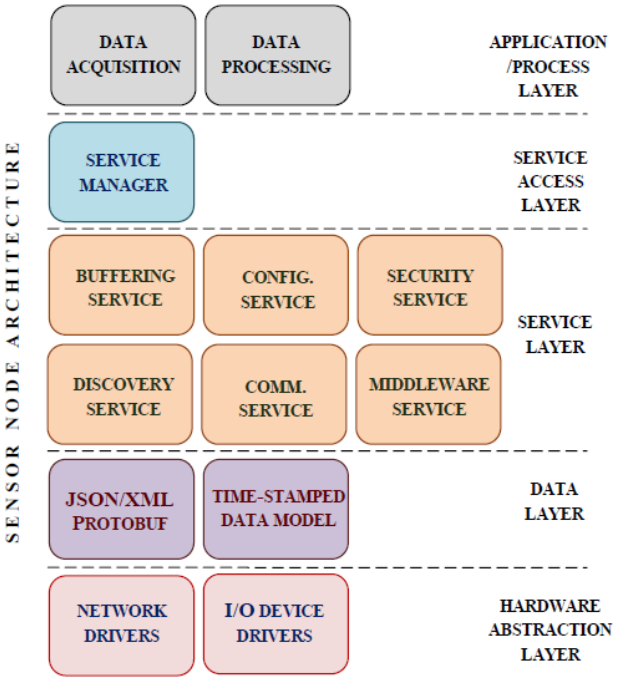

Fig. 1. Sensor node architecture for NCS

This component enables unified data-agnostic service access model, support for local or remote inter-node data communication and access control. It acts as a dispatcher of service request initiated from local application processes and local or remote services. The common system services and the support for different data representations, including time-stamped data model is given at service and data layers. NCS specific services are related to data buffering, configuration of individual services and sensor integration. The access to platform-specific or board-specific hardware resources, regarding network communication, system clock and RTC, data storage and I/O operations, is provided through dedicated device drivers found at hardware abstraction layer.

The component view of sensor node architecture is presented in Fig. 2. Service based implementation model, support for the configuration of network accessible components and channel-based data access model are adopted from the underlying IEEE 1451 group of standards. Inter-node data communication within the service-oriented NCS is performed over standard communication client-server architectural model. Different connectivity options and communication standards are available, including Smart transducer web service (STWS) interface, implemented as an additional layer at the top of the IEEE 1451.0 stack. From the information point of view, communication with passive system components is performed over two different data paths supporting data exchange (IDP) and service configuration (CDP). The information transferred over IDP is given according to time-referenced data model. Together with inter-node time synchronization, this data model enables time-aware execution of sensor services. The IDP data flow is managed by service agents (SAs), unique middleware components capable for inter-channel data communication [22-24].

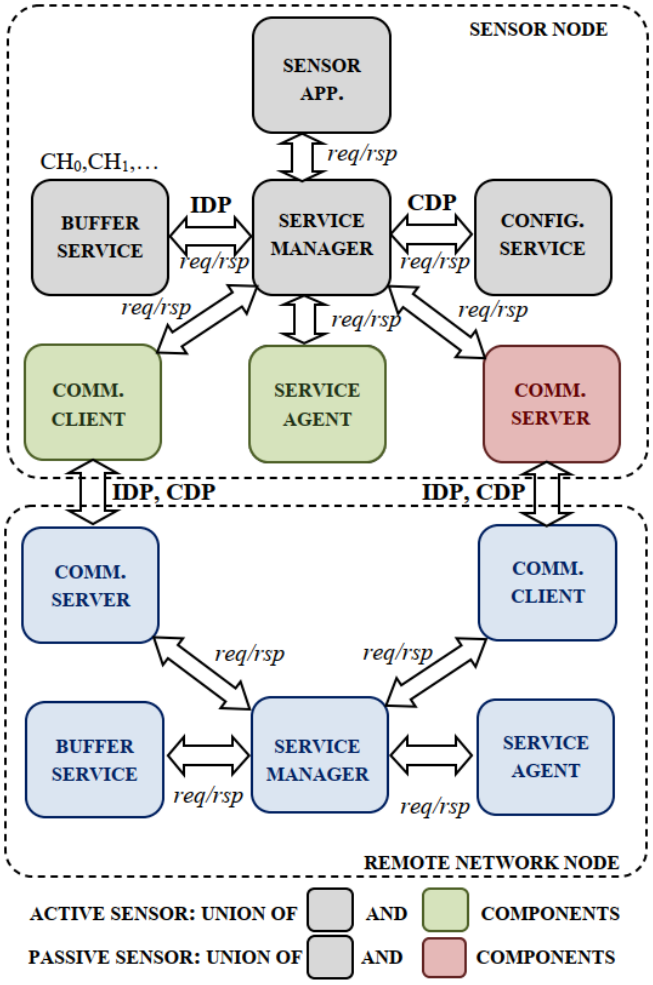

Fig 2. Different sensor node configurations from component-oriented view: (a) passive configuration and (b) active sensor node configuration

In the case of sensing functionality, channel (CH_i) represents the logical abstraction of physical sensor's buffering data structure, e.g. IDP communication endpoint [25]. While the buffer write operations are related to the storing of time-stamped data samples, the buffer read operations are associated to the execution of remote or local service request initiated by dedicated SA. The details of SA operation are explained in [24].

Since the service agent's operation is independent of its physical location, differently customized sensor node architectures are available, as shown in Fig. 2. Passive sensor node operation resembles pull data-processing model, since the service agent, accessing the sensor data, is located at remote network node (Fig 2a). On the other hand, active sensor operation is also supported in a push-like data access model, where transport of sensor data is triggered and managed by dedicated service agent, located at the sensor node (Fig. 2b). The model for inter-component data exchange is given in the form of request-response messaging pattern (*req/rsp*) through the service manager component, which acts as a service proxy and an access and security control gateway [26].

III. SENSOR NODE OPERATION

The detailed thread-level sequence diagram of all system components relevant for passive sensor node operation is given in Fig. 3. Practically all threads, according to the event-based processing model, are waiting for the notifications on particular events, which will trigger thread specific actions.

During the standard sensor operation, data acquisition and processing triggers local service request, resulting in buffer write operation *buff_wr()* according to the time-stamped data model. For the sake of simplicity, execution of time-related services is omitted from the presented diagram, although is part of data processing operations at the application layer.

As a part of NCS control loop operation, the sensor data access over the IDP is also illustrated in Fig. 3.

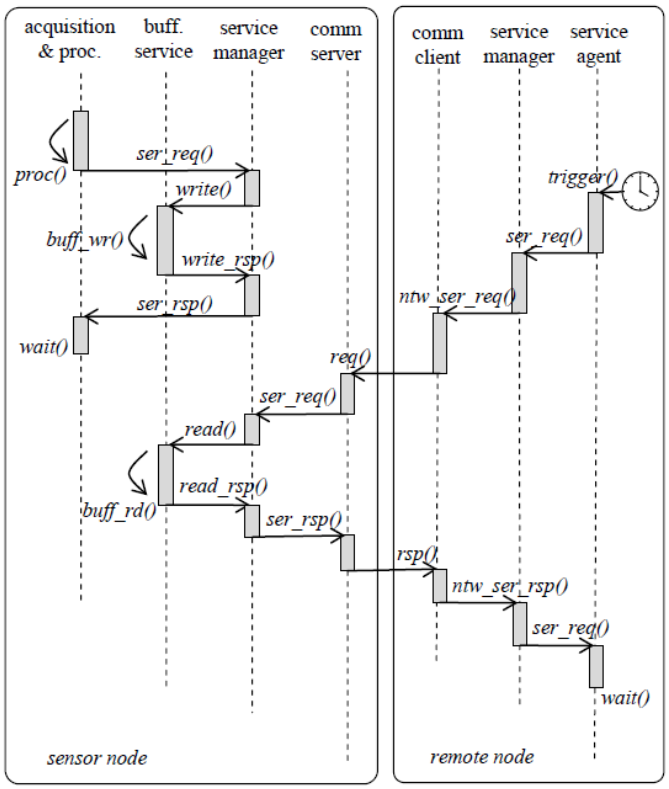

Fig.3 Diagram of the standard passive sensor node execution sequence during NCS operation

After the timer event notification triggers SA, it performs the sequence of read and write operations directed toward particular service provider and consumer endpoints specified in IDP configuration. Since the passive sensor node architecture, SA component is deployed at remote network node. Endpoint read operation, invoked by SA, in the form of local service request, e.g. *ntw_ser_req()* over the service manager effectively invokes buffer *buffer_rd()* operation at sensor node side. This service request is processed by sensor thread providing the read service response with the previously undelivered time-stamped sensor data from local sensor buffer. The read service response is passed by sensor threads to SA over *ntw_ser_rsp()*. Upon the reception of sensor data, SA continues with local or remote write operations to transfer the data to the destination endpoint buffer. The thread

execution sequence associated to write operations is not included in the presented diagrams, since is not related to the group of sensor side operations. One should have in mind that the sensor operation analyzed in the previous discussion assumes the thread-level actions of individual components is driven by the regular sequence of the events.

IV. CONCLUSION

In this paper, a novel architecture of the NCS-suited sensor node is presented. While maintaining the benefits of service-oriented architecture, introduction of the service access layer over the pool of services bring additional flexibility for the NCS integration regarding implementation of the security and discovery mechanisms. Additionally, network transfer of the sensed data is supported both in passive mode, where sensor node effectively acts as a classical data server, and in active mode, where sensor node acts as a configurable data publisher in publish-subscribe data exchange model. The architecture is agnostic to utilized network topology and protocols, as well as specific data acquisition and processing requirements. Since these functionalities are placed in different architectural layers, their implementation is decoupled from service management.

Development of the complementary architectures for the actuator nodes and control-performing nodes in NCS, as well as investigation of the optimal data transfer scheduling within the SOA-based NCS in regular and security threatened operation are planned as a part of the future work.

Exploring the limits of hardware/software co-design

Haris Turkmanović, Filip Mijušković, Ivan Popović

***Abstract* – Various software and hardware techniques have been developed to improve operational properties of an embedded system. In this paper we investigate the potential of hardware/software co-design in the domain of system execution performance. As a target application domain, we selected a class of multimedia applications characterize with extensive number of memory operations. In order to analyze the effectiveness of hardware/software co-design we introduced embedded system metric parameters to quantify system execution performance and its hardware complexity. The profiling of system performance was conducted for different hardware configurations build on FPGA platform while executing several characteristic control flow structures. The analysis has revealed the significant potential of hardware/software co-design in the domain of embedded system optimization.**

Key words: embedded system; performance; FPGA platform; co-design; optimization techniques, control flow

I. INTRODUCTION

Embedded system optimization domain is commonly related with the system execution performance, resource utilization, system energy and power consumption, cost and size reduction, etc. System operational properties including its execution performance and can be improved through the utilization of different software and hardware techniques. Some basic software approaches are: selection and efficient implementation of data processing algorithms, organization of data structures, code-level optimization, etc. On the other hand, hardware techniques are based on concurrent hardware processing, parallel computing, custom logic design, CPU core design, hierarchical organization of memory subsystem, etc. The effectiveness of the particular software-hardware optimization techniques depends on the specific target application domain of the embedded system. This target application domains can be classified into three main classes: multimedia applications, front-end telecommunication applications and network component applications [1]. Focus of our paper is in multimedia application domain with the diversity of image and video processing applications. The common attribute of this application domain is related to the processing of the huge amount of data, preferably organized as loop-based repetitive control flow structure accessing multidimensional array of data structures.

There are numeral research studies and scientific papers which evaluate different software and hardware optimization techniques based on embedded system execution performance optimization. One of the software optimization approach found in [2] analyzes the possibilities and outcomes related to the reduction of processing overhead derived from looped program execution. An additional research presented in [3] analyzes the influence of *inner for loop* and *no inner loop* construct on execution performance. The analysis was carried out in various programming languages and it was shown that in all used program languages *inner for-loops* have better execution performance than *no inner loops*. As a general remark it was given that two equivalent programs written in the same language and running on the same platform, have different performance depending on the coding style. The investigation given in [4] explores the effects of *loop unrolling* techniques on execution performance. Similar analysis found in [5] is investigating applicability and effectiveness of code optimization techniques based on function inline expansion methods. It has been shown that method can improve spatial locality of data access resulting in more efficient use of caching mechanism.

In addition to software-based approaches, different hardware techniques were investigated in the context of embedded system performance optimization. The most commonly investigated hardware design approach is related to a form of memory sub system organization. Especially, accessing data structures located in slower off-chip memories introduces significant CPU stall cycles, decreasing its execution performance. Research published in [6] analyses properties of hieratically organized memory subsystem and cache optimization techniques. Similar results presented in [7] quantify the effectiveness of caching mechanism in the multimedia application domain. As a general observation it was found that multimedia application has a lower data cache miss rate.

The aim of our research is to investigate the limits which can be achieved by a combination of software and hardware techniques. Consequently, already known techniques, which may influence the achievement of these limits, are considered in our analysis. On the other hand, in order to investigate the impact of various hardware configurations, an FPGA platform has been selected. This platform type provides the ability to create an arbitrary hardware and software environment for exploiting different optimization techniques. In particular, we analyze sequential and looped control flow structures with no

Ivan Popović is associate professor at School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: popovici@etf.rs).

inner loop constructs, with and without inline function expansions. From the pool of hardware-related techniques, we analyze the effects of advanced CPU core features on execution performance, as pipelined execution and branch prediction, as well as the effects of different program and data memory organizations.

After this introductory part, the following section introduces the metrics parameters which quantify contribution of hardware and software techniques to the embedded systems execution performance. Section III presents realization details of the system hardware configurations and describe program control flow structures used in our analysis. The results of the applied performance optimization and as well, hardware requirements of utilized hardware and software techniques, with the associated discussions, are given in section IV. Concluding remarks and plans for future work are given in the final section.

II. System Design and performance metrics

This chapter introduces embedded system metric parameters in order to quantify effectiveness of different software and hardware techniques in the context of system execution performance and its complexity. Introduced parameters enable numerical comparison and characterization of different hardware/software configurations.

On one hand, the complexity of an overall embedded system given as a collection of data processing and data storage elements is counted through hardware related parameters. On the other hand, software related parameters quantify the performance properties of the program execution related to the control flow structure, properties of instruction set architecture, etc.

In the analysis presented in this paper, we selected the subset of system metrics parameters containing Hardware Complexity and Execution Performance parameters.

System Hardware Complexity (HC) is introduced to uniquely describe the complexity of each hardware configuration. The complexity of the hardware configuration *n* (described as a parameter HC_n) is given as a function of required number of logical elements (LE_n) and the number of occupied memory bits (M_n), in the form:

$$HC_n = f(LE_n, M_n)$$

The expression $HC_{n,m}$ is used to describe the Normalized Hardware Complexity of hardware configuration *n* in respect to the selected reference hardware configuration *m*.

Execution performance parameter given as T_n^i represents the number of system clock cycles required to execute the program flow *i* on the hardware platform *n*.

Similarly with normalized hardware complexity parameter, the symbol $T_{n,m}^i$ is used to express a normalized execution performance of a program flow *i* on a hardware platform *n* (given as T_n^i) in relation to T_m^i, e.g. $T_{n,m}^i = T_n^i / T_m^i$.

Normalized execution performance is used as a Measure of system effectiveness from the execution performance viewpoint. This quantitative measure enables ranking of comparable systems in the domain of applied optimization techniques. [8]

III. System overview

This section describes the hardware and software related details of an embedded system used in our analysis. Hardware configurations, realized on FPGA platform, are selected in order to investigate the influence of the processing unit and memory subsystem properties on execution performance [2][11]. Similarly, to examine the effects of software optimization techniques, we consider several control flow structures, as given below.

A. Hardware configurations

All presented hardware configurations are given as uniprocessor systems with the NiosII processor core [9]. Two soft-core CPU implementations, *NiosII/f* fast core and *NiosII/e* economy core, are considered as boundary choice, in terms of the most complex and the simplest core design, respectively. The NiosII fast core, in addition to features of the economy core, supports *pipelined program execution*, *dynamic branch prediction*, *instruction and data caching*, *tightly coupled memory interfaces* as well as enhanced instruction execution time.

The details of selected hardware configurations are summarized in Table 1. Configurations 3 and 4 are chosen in order to examine the effects of memory subsystem organization on execution performance, where configuration 3 supports L1 instruction caching while configuration 4 has L1 instruction and L1 data cache. Configuration 5 and 6 are built with fast On-Chip SRAM memory directly accessible by processor core through the dedicated tightly coupled interface, where configuration 5 utilizes this memory only for the instructions while configuration 6 utilizes memory for data and instruction access.

TABLE I
OVERVIEW OF HARDWARE CONFIGURATIONS

Configuration NO	Processor Core	Data Memory	Data Cache	Instruction Memory	Instruction Cache
1	e	*SDRAM*	*NO*	*SDRAM*	*NO*
2	f	*SDRAM*	*NO*	*SDRAM*	*NO*
3	f	*SDRAM*	*NO*	*SDRAM*	*YES*
4	f	*SDRAM*	*YES*	*SDRAM*	*YES*
5	f	*SDRAM*	*NO*	*On-chip RAM*	*NO*
6	f	*On-chip RAM*	*NO*	*On-chip RAM*	*NO*

All hardware configurations presented in Table 1. are built on *EP4CE115F29C7* FPGA chip from *Altera Cyclone IV* device family [10][11]. As a hardware environment for our analysis we selected *Terasic DE2-115* development board [12] with external SDRAM memory [13] available through *Altera SDRAM controller* [14]. The *Cyclone EP4CE115* device equipped on the *DE2-115* features 114480 logical elements (LEs) and up to 3.9 Mbits of RAM [11].

The hardware requirements for each of the hardware configurations in the context of utilized LE and memory bits, quantified through calculated Hardware Complexity, parameter is given in Table 2.

TABLE II
HARDWARE CONFIGURATIONS IMPLEMENTATION DETAILS

Configuration No i	No Of Logic elements	No Of bits	HC_i
1	3332 (*2.91%*)	11264 (*0.28%*)	0.61
2	4536 (*3.96%*)	11776 (*0.3%*)	0.82
3	4642 (*4.05%*)	16320 (*0.41%*)	0.84
4	5165(*4.51%*)	51776 (*1.3%*)	0.95
5	4622(*4.04%*)	273920 (*6.88%*)	0.9
6	4833(*4.22%*)	1322496 (*33.22%*)	1.18

It should be noted that for profiling NiosII system, *Performance Counter* [11] unit is embedded in each hardware configuration. The unit is used to measure a number of clock cycles which is required for the execution of the program section defined through BEGIN/END statements [15].

B. Control flow structures

In order to analyze the influence of software optimization techniques on the execution performances of applications with intensive memory accesses [1], we selected the initial simple control flow structure 1 in the form of a sequence of memory write operations to successive memory locations. The similar structure, but with non-sequential memory access is given as control flow 2. Control flow structures 3, 4 and 5 are realized in the form of a repetitive control flow with sequential, non-sequential memory access, and with nested function call encapsulating sequential memory access, respectively. Characteristics of each control flow structures are listed in the Table 3.

TABLE III
PROPERTIES OF PROGRAM FLOW STRUCTURES

Control Flow Structure No	Code size	Memory access	Instruction memory access	Data memory access
1	*2KB*	700	500 (71%)	200 (29%)
2	*2.4KB*	800	600 (75%)	200 (25%)
3	*32B*	2200	1600 (72%)	600 (28%)
4	*32B*	2200	1600 (72%)	600 (28%)
5	*136B*	4600	3400 (74%) (1600+1800)[1]	1200 (26%)

Properties given in Table 3 are derived from assembly codes which are generated from corresponding control flow structures written in C programming language.

IV. HARDWARE/SOFTWARE CO-DESIGN ANALYSIS

The results obtained by measuring execution performance, after the application of different hardware and software configurations, are analyzed in this section. Some of the effects, at first glance, give unexpected performance since the spatial and temporal properties of memory access resulting in dynamic system behavior. The details of the analysis related to the hardware and software design issues are given in the following paragraphs.

A. Software related effects

System hardware configuration 1 is used to quantify the control flow structure effects on the execution performance. Since this hardware configuration does not include any of advanced hardware features, it is ideal found to quantify these effects. Obtained results are shown in Figure 1.

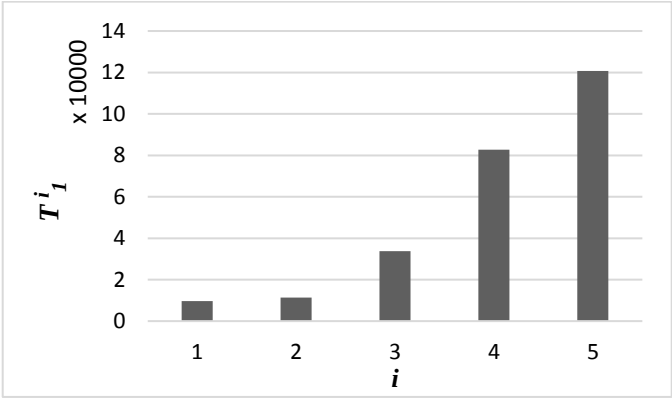

Figure 1 – Execution time of different control flow structures, measured on hardware configuration No.1

Based on the execution time properties shown in Fig. 1, it is noticeable that the control flow structure significantly affects the execution performance. In relation with control flow properties from Table 3, we can conclude that these effects are directly related to the total number of memory accesses. In other words, the program flow structure 1 achieves the best performance on a simple processor core because it requires the least memory accesses. However, control flow 1 exhibits low code density and poor maintainability since it has the highest number of code lines.

TABLE IV
RATIO OF EXECUTION PERFORMANCE WITHOUT ($T^i_{wo,4}$) AND WITH ($T^i_{w,4}$) CACHE FLUSHING MEASURED ON CONFIGURATION NO.4

Control flow structure	1	2	3	4	5
$T^i_{wo,4}/T^i_{w,4}$	2.66	5.52	1.20	1.66	1.37

The execution performance properties related to compulsory cache misses, found in initial code execution or after the context switching, are analyzed as well. The profiling of execution performance is performed with and without flushing cache content prior to code execution. As these effects are associated with cache-based systems, our analysis included hardware configuration 3 and 4 with L1 cache memory. The results obtained by the measurement program execution properties, for hardware configuration 4, are given in Table 4.

As noticeable from Table 4, these effects are the most observable for the control flow structure 2, since the spatial

[1] 1600 memory accesses are realized in main program while 1800 memory accesses are obtained in function

and temporal properties of memory access.

B. *Hardware related effects*

In order to analyze the CPU design related effects on execution performance, hardware configuration 1 and 2 are selected. Both configurations utilize SDRAM-only based design of the memory subsystem. The results shown in Figure 2 represent execution performance of defined control flow structures executed on hardware configuration 2. The results in Figure 2 are normalized with respect to execution performance of same control flow structures executed on hardware configuration 1.

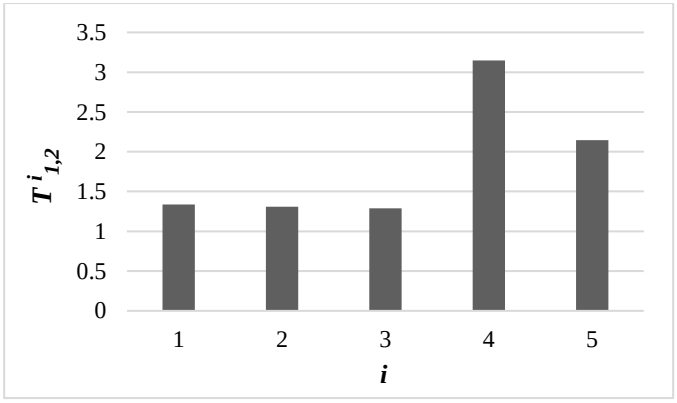

Figure 2 – Normalized execution performance for SDRAM-only hardware configurations, T_1^i/T_2^i

The results given on Fig. 2, illustrate the potential of performance-cost tradeoff in *NiosII* core design. As noticeable advanced CPU related features found in *NiosII/f* core bring execution performance improvements in all control flow structures. The improvement is most prominent for control flow 4 organized as repetitive structure with non-sequential memory access since *NiosII/f* processor core supports dynamic branch prediction and pipelined code execution. During results analysis one should have in mind that hardware configuration 2 requires a significantly higher number of hardware resources compared to configuration 1, as given in Table 2.

The following discussion analyzes the effects of memory subsystem organization on execution performance. First approach explores the benefits of hierarchically organized memory system which is exploited in hardware configuration 3 and 4. The second approach considers utilization of fast on-chip memories. These memories have low memory access time for storing code and data sections and they are used in hardware configuration 5 and 6. In order to quantify the contribution of each hardware configuration, configuration 2 is selected as the reference system configuration since it has the same core design as configurations 3, 4, 5 and 6.

Normalized execution performance, observed for hardware configuration 3 with L1 instruction cache, is presented in Figure 3.

From the Fig. 3 we can conclude that the instruction cache brings improvement in all control flows, especially in those given in the form of repetitive structures due to higher code spatial locality. The support for data caching, found in configuration 4, brings additional improvements in the execution performance of flows 3 and 5 because of higher spatial locality in consequence of sequential data memory access. Obtained results confirmed that assumption, since the obtained execution performance was improved about 9 times compared to the system configuration without instruction and data caches (see Table 6).

TABLE V
OBTAINED EXECUTION SPEEDUP AFTER ADDING DATA CACHE IN SYSTEM WITH INSTRUCTION CACHE

Control flow structure	1	2	3	4	5
$T^i_{3,4} = T^i_3/T^i_4$	0.89	**0.37**	2.40	1.68	1.93

During the analysis it was noticed that adding data cache in the system configuration with instruction cache, can lead to significant decrease of execution performance as can be viewed from Table 5. This effect is manifested in the case of control flow 2, where performance was decreased almost 3 times. This significant reduction in execution performance comes from the fact that this control flow structure has low temporal and spatial locality which increases data miss rate. One should have in mind that single data miss producing additional CPU stall cycles.

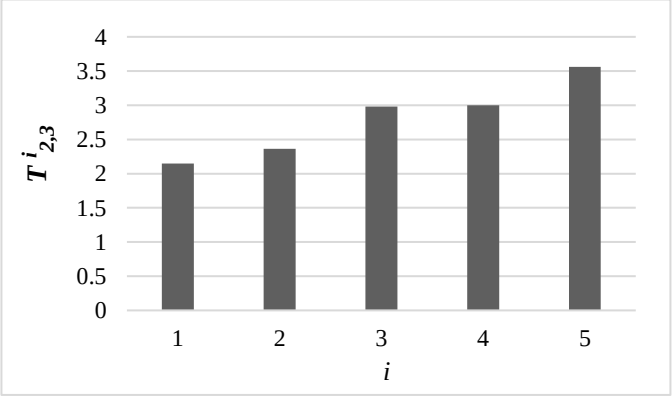

Figure 3 –Normalized execution performance of different control flow structures measured for hardware configuration No. 2 in respect to No. 3.

Hardware configuration 5 and 6 are used to explore the system performance limits since utilizing fast on-chip memories directly accessible through dedicated CPU tightly coupled interface. The use of fast memory for program code sections can significantly contribute to the execution performance, especially in the case of program flows 1 and 2. The performance improvement is expected since most memory accesses are related to instruction fetching. Although the execution performance is improved extensively (around 15 times), one should have in mind that hardware complexity of configuration 5 and 6 is significantly increased, as given in Table 2.

In comparison to configuration 3 with L1 instruction cache, configuration 5 introduces performance speedup, especially noticeable for control flows 1 and 2 with sequential structure of program flow.

Hardware Configuration 6 was introduced to examine the extreme limits of system performance, where both - data and instructions - are directly accessible from fast on-chip memory without misses. The results obtained in this analysis show that the individual performance increase is up to 60% for all control flow structures.

Obtained limits of applied hardware and software techniques and their combinations are summarized in Table 6.

TABLE VI
EXPLORED LIMITS OF HARDWARE/SOFTWARE CO-DESIGN IN PARTICULAR PROBLEM DOMAIN

No	Technique	Parameter	Max Speedup
1	Loop unrolling	T_5^3/T_5^1	9.54
2	Sequential memory access	T_4^2/T_4^1	2.61
3	Inline function	T_6^5/T_6^1	13.32
4	Hierarchical memory organization - caching	T_2^5/T_4^5	9.43
5	Core design	T_2^4/T_1^4	3.15
6	Directly coupled fast memory access	T_2^1/T_6^1	14.28
7	Inline functions and caching	T_1^5/T_4^1	32.43
8	Inline functions and directly coupled fast memory access	T_1^5/T_6^1	239.15
9	Inline functions and core design	T_1^5/T_2^1	16.81
10	Loop unrolling and caching	T_1^3/T_4^1	8.97
11	Loop unrolling and directly coupled fast memory access	T_1^3/T_6^1	66.98
12	Loop unrolling and core design	T_1^3/T_2^1	4.30

V. CONCLUSION

We analyzed the effectiveness of most commonly used hardware and software techniques in embedded system performance optimization. The limits of embedded system execution performance are revealed through the combination of applied techniques. Our analysis has shown that in the domain of software-based techniques, the significant advances can be achieved by applying adequate control flow structures. Based on the control flow properties, such as the number of memory accesses, spatial and temporal locality, the efficiency of particular software techniques is directly linked to the selected system hardware configuration, providing the background for hardware/software co-design. Furthermore, introduction of embedded system metrics parameters enables additional analysis of different complexity-performance tradeoffs in hardware/software co-design, as a part of future work.

Analyzing the Thermal Imaging Histogram using FPGA

Igor Beracka, Petar Marin, Nikola Latinović, *Member, IEEE*, Ilija Popadić, *Member, IEEE,* Miroslav Perić, *Member, IEEE*

***Abstract*—This paper describes a histogram calculation method for thermal images implemented in FPGA technology. Thermal images display the infrared radiation of objects, which renders them particularly useful in situations where objects of interest are to be separated regardless of the state of illumination in the image. This is achieved by altering the brightness and contrast of the raw image. For that purpose, image histogram is beneficial as it provides information about the values of these correction parameters. Additionally, histogram estimation is essential for picture compression, given that it indicates the areas of image where most information is stored. Laboratory tests results are displayed in this paper and conclusions are drawn.**

***Index Terms*—histogram, FPGA, contrast, brightness, compression.**

I. Introduction

A thermal image (thermogram) is a digital representation of a scene and a measure of the thermal radiation emitted by objects in the picture [1]. Every object hotter than absolute zero (-273.15℃) emits infrared radiation as a function of its temperature - the level of radiation raises with increase of object temperature. Thermal images are captured via thermographic cameras, which are devices capable of sensing this radiation in the form of infrared light. Thermal images are usually presented as levels of grey ranging from black (cold) to white (hot).

The histogram of digital image with grey levels in the range [0, L - 1] is a discrete function

$$h(r_k) = n_k, \tag{1}$$

where r_k is the kth grey level (called bin) and n_k is the number of pixels in the image having grey level r_k [2]. It is common practice to normalize a histogram by dividing each of its values by the total number of pixels in the image. Histogram manipulation can be used effectively for image enhancement because they are simple to calculate in software and economical for hardware implementations. Histograms are also very useful in image compression.

The main objective of this work is to make experimental environment for creating the processing function for dynamic range compression of luminance signal from N to M (N>M) bits without loosing important details from Fig 1.

Heaving in mind good performance results for usage FPGA technology for image processing reported in [3] and [4] we have decided to use this technology, rather than multi-core microprocessor and graphic processing unit that would be used for further processing steps. The main contribution of this paper is that with our design we have proved efficiency of FPGA implementation of histogram and its analysis usefulness in thermal imaging. The paper is structured as follows: in section II we described overall video signal processing that we have implemented, in section III we have focused on FPGA part of implementation, in section IV we give remarks of practical implementation and laboratory setup. Finally, in section V we gave test results followed by conclusion given in section IV.

II. System Description

This system contains thermal camera, CL (Camera Link™) [5] to parallel converter board, frame grabber implemented on FPGA module, parallel to HDMI (High-Definition Multimedia Interface) [6] conversion board and PC (Personal computer).

Camera sends raw thermal image through CL to parallel conversion board to frame grabber, which calculates histogram of raw frame, processes frame and calculates histogram of corrected frame. Video is streamed from frame grabber through ADV7511 integrated circuit to monitor.

Frame grabber is also connected with PC through serial port and histograms are plotted in MATLAB® GUIDE (Graphical User Interface Design Environment) [7].

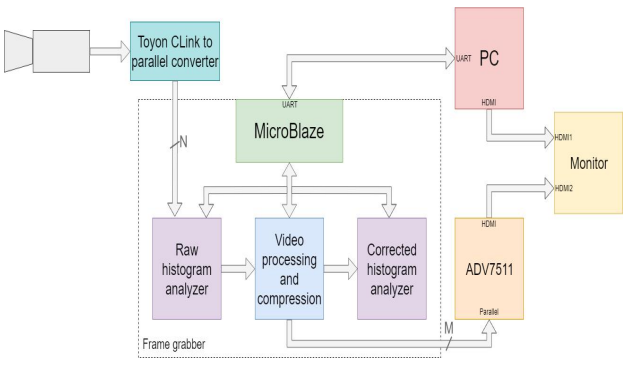

Fig.1. System block diagram.

Petar Marin is with the Institute Vlatacom, 5 Bulevar Milutina Milankovića, 11020 Belgrade, Serbia (e-mail: petar.marin@vlatacom.com).

Nikola Latinović is with the Institute Vlatacom, 5 Bulevar Milutina Milankovića, 11020 Belgrade, Serbia (e-mail: nikola.latinovic@vlatacom.com).

Ilija Popadić is with the Institute Vlatacom, 5 Bulevar Milutina Milankovića, 11020 Belgrade, Serbia (e-mail: ilija.popadic@vlatacom.com).

Miroslav Perić is with the Institute Vlatacom, 5 Bulevar Milutina Milankovića, 11020 Belgrade, Serbia (e-mail: miroslav.peric@vlatacom.com).

III. FPGA IMPLEMENTATION

FPGA system (Frame grabber) contains two identical histogram calculator modules (one for raw frame histogram calculation and another for calculating histogram of corrected frame after processing and compression), module for correction of brightness and contrast and MicroBlaze™ micro-controller for controlling the system and connecting it with PC through UART (Universal Asynchronous Receiver/Transmitter).

Histogram calculation module have 3 generic parameters:
g_NUM_OF_BINS - number of histogram bins;
g_FRAMES_TO_ACQUIRE - Number of frames to acquire for histogram calculation;
g_HIST_BIN_BIT_DEPTH - Depth of histogram bin counters and output registers.

With these generics user can define how many MSB (Most significant bits) to take from input signal for calculation, how many frames to take for results averaging and depth of counters results registers in bits respectively.

FSM (Finite State Machine) of this module contains 4 states and it is shown on Fig 3. In IDLE state FSM waits for start command from MicroBlaze™, in WAIT_NEW_FRAME state it waits for new frame to start calculating histogram from first pixel of the picture, in CALC_HIST state it calculates histogram for specified number of frames and in COPY_RESULTS state it stores the results into registers dedicated for that.

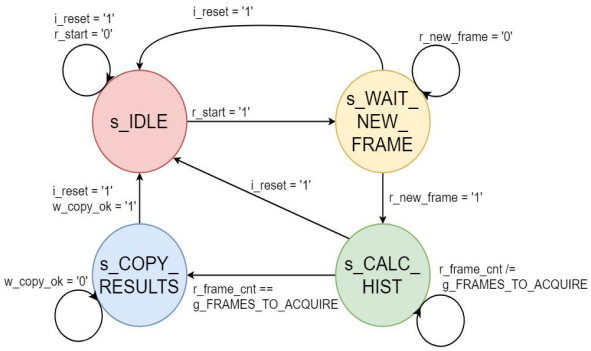

Fig. 2. Histogram calculator FSM state diagram .

FPGA module logic cell usage is measured for different number of histogram bins (16, 32, 64, 128 and 256) used for histogram calculation module and results are given in graph below.

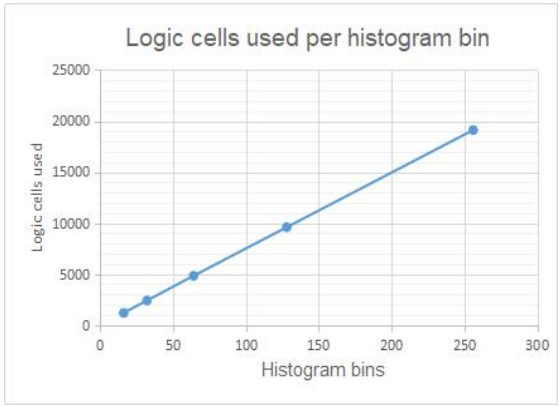

Fig. 3. Logic cells used per histogram bins.

Brightness and contrast correction module is implemented with the use of DSP (Digital Signal Processing) IP (Intellectual Property) core and registers for storing values of user defined brightness and contrast. The function for correction is defined with equation (2):

$$Y = C \cdot X + B, \tag{2}$$

where X is input data (16 bits long), C is contrast (range 0 to 31.984375), B is brightness (range -8192 to 8191) and Y is result truncated to 8 MSB. At this stage we have assumed that linear function (2) is good enough to show important parts of histogram. Better option for correction of brightness and contrast would be non-linear function, but that's out of scope of this paper.

MicroBlaze™ is instantiated and connected with these modules, so user can send commands with MATLAB® GUI (graphical user interface) application through UART.

IV. PRACTICAL IMPLEMENTATION

In this chapter we will show and describe used components and test the frame grabber module implemented on FPGA board.

Thermal camera used in this work is Xenics XTM-640™ [8] with Ophir lens, which sends 50 frames per second of VGA (640x480 pixels) signal with 16b pixel depth. For Camera Link™ to parallel signal conversion we are using Toyon Boccacio™ [9] converter board. Frame grabber is implemented on Mercury PE1 development board with Mercury+ KX2 FPGA module with Xilinx Kintex 7™ [10] on it. For parallel to HDMI conversion we are using Toshiba ADV7511 parallel to HDMI integrated circuit [11].

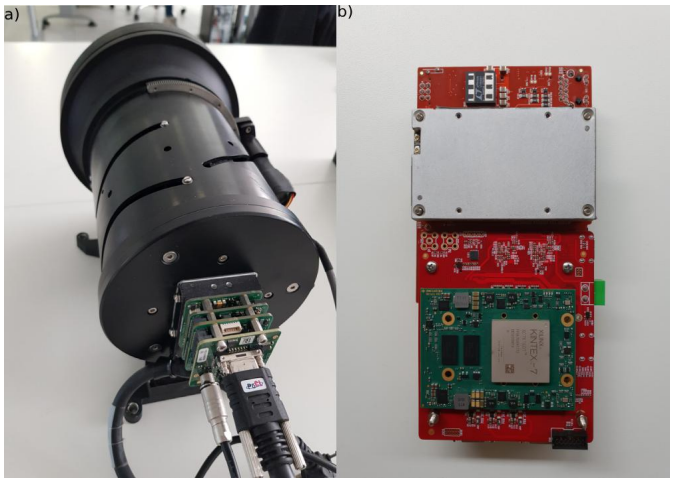

Fig. 4. a) Xenics XTM-640™ camera with Ophir lens, b) Video signal processing module with Mercury PE1 development board and Mercury+ KX2 FPGA module.

As we mentioned in the system description part, software used for creating graphical user interface is Matlab™ GUIDE. On Fig 6 you can see implemented GUI, where are shown controls for serial port configuration, raw and corrected frame histograms calculation, brightness and contrast adjustment, grab threshold points (for grabbing low and high threshold and automatically calculation of brightness and contrast values) and others which are out of scope of this

paper. There is also shown information about Camera Link interface (input) and HDMI (output) signals.

Big black surface on the left side of GUI is place where we put grabbed frame from input signal, which user can save in different picture formats.

Histograms of raw and corrected frame are plotted in new figures and they both have colour bar below to make it intuitive to the user which bin is corresponding colour representing. Number of pixels in frame is normalized to 1, so on the y axis is shown the probability of occurrence of grey level r_k.

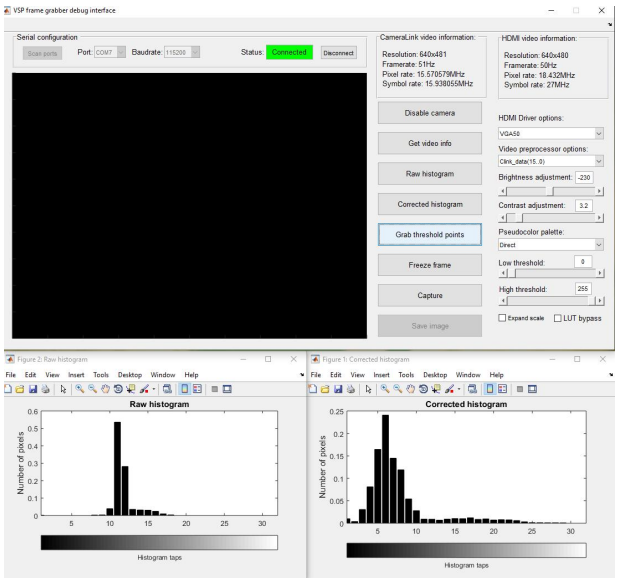

Fig. 5. Graphical user interface.

V. Results

For presentation of the results we have created an environment with a man holding a cups of hot and cold water in his hands. This set up is chosen because it's good for separating of cold and hold objects from picture. On figure below you can see thermal camera, video signal processing module (connected to PC) and person with hot water in black cup (in his right hand) and cold water in white cup (in his left hand).

Fig. 6. Experimentation environment.

The first thing that we have tested is brightness and contrast correction module, where we have captured raw frame from thermal camera (Fig 8a), calculated the histogram of that frame (Fig 8b) and from that histogram extracted the region of interest. Red vertical lines with arrows are added for better description of what's happening with histogram after correction (which part of histogram is expanded).

In the first test we have chosen to expand region from 6th to 15th bin, because there are most pixels from image stored. Resulting image grabbed after correction is shown on Fig 8c, and its histogram is shown on Fig 8d. The main differences between figures 8a and 8c can be seen on cold and hot cups, but other details are also improved on the corrected image (subject face, hands and watch).

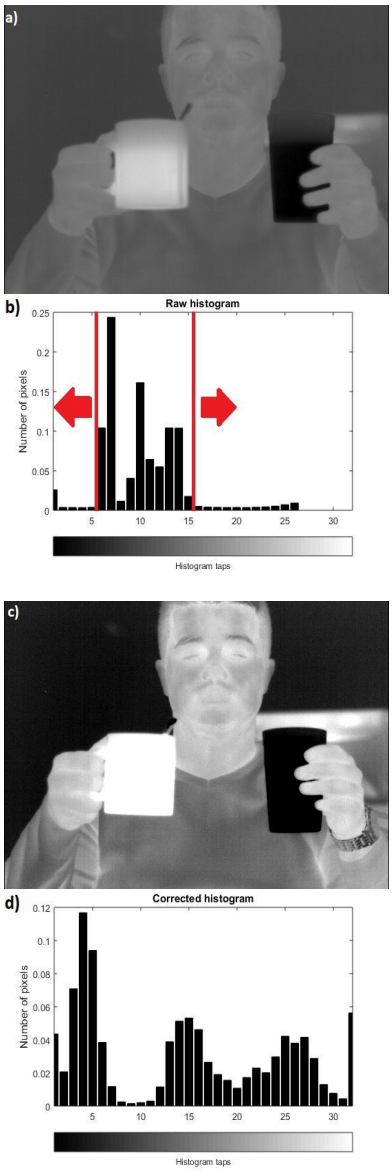

Fig. 7. a) Raw thermal image, b) Histogram of raw thermal image with two vertical lines and arrows which shows what part of histogram is expanded, c) Corrected image, d) Histogram of corrected image.

On the next two figures (9 and 10) we will show cold and hot object detection from raw thermal image histogram. The environment is same for all experiments, but some small details can change in time (subject movement, background changes...), so there must be a little changes between raw histograms shown on figures 8, 9 and 10.

In order to detect cold objects on the picture we have expanded 1st to 6th bin from raw histogram shown on Fig 9b. Resulting image after histogram correction and corrected

histogram are shown on Fig 9a and 9c respectively. On Fig 9a we can clearly see that cold water is detected, while we can also still see the edges of subject because he is hotter than background.

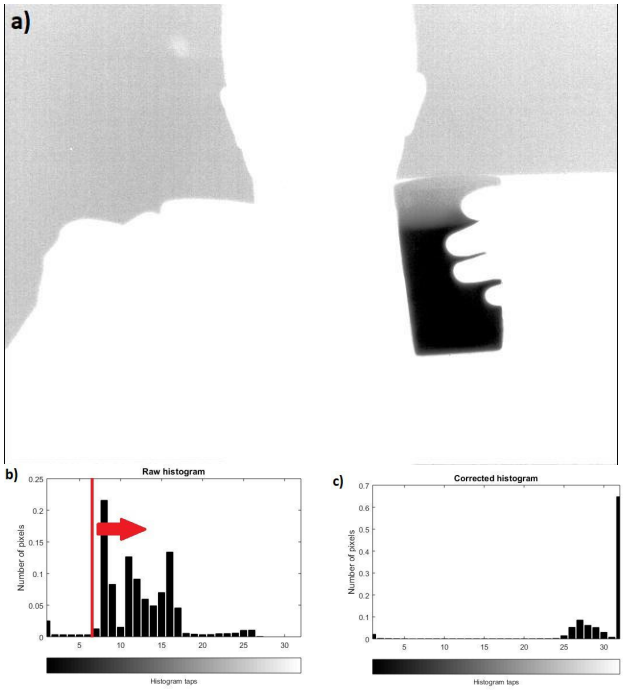

Fig. 8. a) Image with separated cold water, b) Histogram of raw thermal image with vertical line and arrow which shows what part of histogram is expanded, c) Histogram of image with separated cold (dark) pixels.

The last thing that we wanted to detect is hot water, and in order to do that we have expanded 19th to 32nd bin. Raw and corrected thermal image histograms are shown on figures 10b and 10c respectively. Resulting image is shown on Fig 10a, where we can see a cup of hot water, part of monitor from background and contour of hottest parts of subject face.

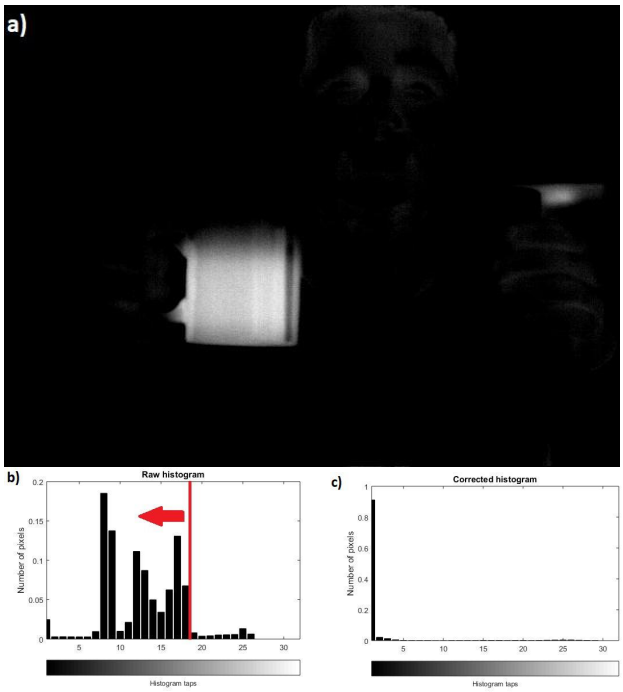

Fig. 9. a) Image with separated hot water, b) Histogram of raw thermal image with vertical line and arrow which shows what part of histogram is expanded, c) Histogram of image with separated hot (light) pixels.

Values chosen for B and C parameters from function (2) for these three different corrections are stored in the table below.

TABLE I
BRIGHTNESS AND CONTRAST PARAMETERS FOR DIFFERENT FIGURES

VI. CONCLUSION

In this paper, histogram calculation method for thermal images was implemented in FPGA technology. Proposed method reveals superiority of FPGA technology in terms of processing speed when compared to microprocessor or GPU realization. Furthermore, tests carried out in laboratory environment demonstrate how efficient histogram evaluation is for specified linear compression technique.

Future work will focus on evaluating non-linear processing techniques for object detection in low-contrast imagery scenarios.

Design and realization of a Class EF_2 Power Amplifier with GaN FET

Zoran Živanović, *Member, IEEE* and Vladimir Smiljaković

***Abstract*—This paper presents the design of a high frequency class EF_2 switch-mode power amplifier optimized for a 50 ohm load at 13.56MHz. The amplifier basics are briefly explained, including simplified schematics. The prototype has been built and experimental results are presented to support theoretical analysis and to demonstrate the amplifier performance. This practical realization utilizes the newest GaN FET in a low inductance package with small parasitic capacitances capable of switch mode operation up to 50MHz. Previously, the GaN transistors have become widely used in high frequency switching power converters.**

***Index Terms*—Class EF_2, duty cycle, efficiency, GaN, switch-mode power amplifier, zero voltage switching.**

I. Introduction

A large variety of industrial, scientific and medical processes require reliable, low cost high frequency regulated power. Applications include RF plasma processing, dielectric heating, RF welding, magnetic resonance imaging and wireless power systems. Previously, high frequency power was provided by linear power amplifiers with transistors operated in the linear mode with efficiency around 70%. Opposite to them, transistors in switch-mode power amplifiers are operating as a saturated switch with efficiency up to 95%. Unlike standard 50 ohm applications, the load in ISM applications is usually extremely dynamic, ranging from a few ohms to a several hundred ohms including reactive parts. The problem is further complicated by the fact that the process requires the amplifier to operate with large mismatch.

II. Class EF_2 Power Amplifier Basics

The Class E power amplifier is a type of switch-mode RF power amplifier, introduced by Sokal and Sokal in the 1970's [1]. The topology consists of a MOSFET transistor, shunt capacitor, RF choke and a series resonant circuit. The transistor is driven hard enough to saturate at 50% duty cycle. Due to its operation at zero voltage switching, they can deliver RF power up to tens of MHz with efficiencies up to 95%. Single ground referenced power switch experiences a higher voltage stress compared to other topologies ($3.6V_{in}$) [2]. Also, deviations of the load can cause the efficiency drop and permanent damage to the switch. In 2002, Kee presented an overview of the Class EF inverters and a generalized frequency domain based analysis method to determine the voltage and current waveforms of LC resonant networks [3]. Later it was shown that the voltage and current stresses of the Class E amplifier can be reduced by adding resonant network either in parallel or series to its load network [4-6]. The method of adding resonant networks is already used in Class F and Class F^{-1} inverters. Applying this method to the Class E inverters, results in hybrid inverters, which has been referred to as the Class EF_n or Class E/F_n inverters. The subscript n refers to the ratio of the resonant frequency of the added resonant network to the inverters switching frequency and is an integer number greater or equal than 2. If n is an even integer the EF_n term is used and if *n* is an odd integer the E/F_n term is used.

Class EF_2 power amplifier shown in Fig. 1 overcomes some limitations of the class E amplifier. Like the Class E, the resonant components (C1, C3, L3) are tuned to provide zero voltage switching in order to lower the switching losses.

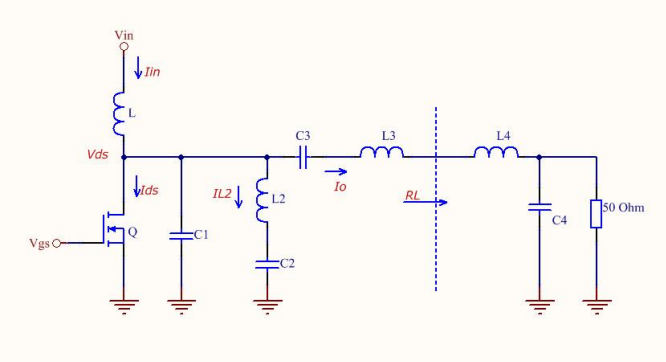

Fig. 1. Class EF_2 power amplifier

Components L2 and C2 are tuned to have low impedance at the 2nd harmonic at the terminals of switching transistor. This leads to a trapezoidal waveform of drain voltage with a peak up to $2.5V_{in}$. Choke inductance L must be high enough such that the input current I_{in} is DC current. The capacitance of shunt capacitor C1 includes the output parasitic capacitance of the power switch. This parasitic capacitance is voltage dependent and it can be difficult to choose an exact value. Loaded Q factor L3C3 branch must be high enough such that the current I_o is sinusoidal. An output matching network is needed (L4, C4) to transform the 50 Ω impedance into the required load resistance R. Class EF_2 amplifiers have higher power-output capability then class E amplifiers. Also its DC input voltage is higher than that of a Class E amplifiers,

Vladimir Smiljaković is with the IMTEL KOMUNIKACIJE AD, Bul. Mihajla Pupina 165b, 11070 Belgrade, Serbia, (e-mail: smiljac@insimtel.com).

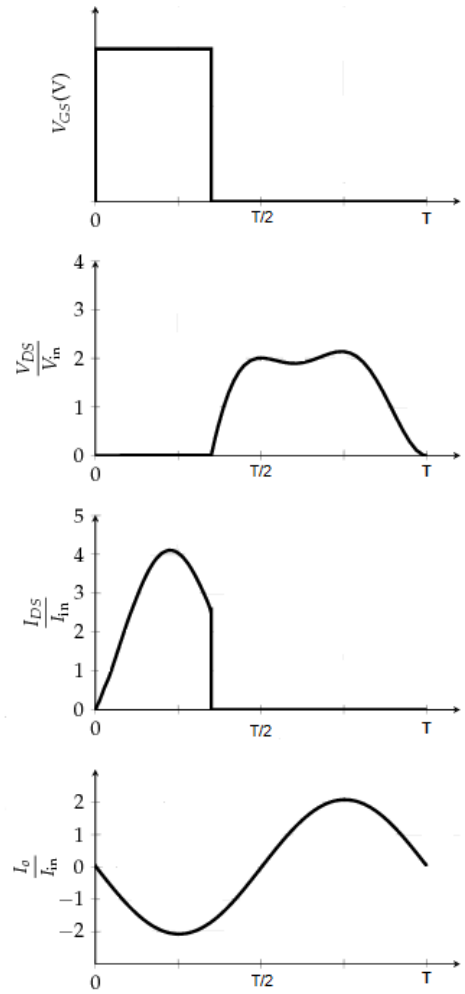

Fig. 2. Class EF_2 voltage and current waveforms

because the Class EF2 reflects a higher DC load to the DC power supply. Practical duty cycle can vary from 30 to 40% opposed to 50% in a class E.

Fig. 2 shows power switch's normalized drain voltage and current waveforms and normalized output current at 35% duty cycle.

III. Design and Analysis

To design class EF_2 RF power amplifier [7] we will start from the design specification given in Table I.

TABLE I
DESIGN SPECIFICATIONS

	Parameter	Value	Units
DC voltage	V_{CC}	28	V
Output power	P_O	40	W
Load	Z	50	Ω
Drain efficiency	η	90	%
Frequency	f	13.56	MHz

Inductor L2 and capacitor C2 must be tuned to a frequency in between the switching frequency and the second harmonic of the switching frequency. The ratio of the resonant frequency of L2C2 to the switching frequency is represented by parameter q_1 and is given by

$$q_1 = \frac{1}{\omega\sqrt{L_2 C_2}} \tag{1}$$

The parameters k is defined as

$$k = \frac{C_1}{C_2} \tag{2}$$

Also the parameter p is given by

$$p = \frac{1}{k+1}\frac{I_m}{I_{in}} \tag{3}$$

The minimum choke inductance required is

$$L_{\min} = 2\pi D \frac{V_{in}}{\omega \Delta i_{L\max}} \tag{4}$$

Series inductance L3 is defined as

$$L_3 = \frac{QR_L}{\omega} \tag{5}$$

Design begins with choosing the value for q_1. Tuning the resonant frequency of L2C2 network to around 1.5 times the switching frequency allow load independent operation to be achieved. We will adopt the value of 1.66 in order to have maximum power output capability. Duty cycle will be set at 30%. The large value for p could result in small value of shunt capacitance C1, lower then parasitic capacitance of available power switches. Low value for p will result in lower efficiency. Finally, we adopt value of 2. Also we will set the maximum input ripple current to be 10%. Knowing that, we have calculated the values of all elements which are shown in the Table II. Based on the value of the input DC voltage and output power we have selected 100V eGaN FET EPC2016C for the power switch.

TABLE II
CALCULATED VALUES

Component	Parameter	Value	Units
Load resistance	R_L	2.50	Ω
RF choke	L	6	µH
Shunt capacitance	C_1	832	pF
Added capacitance	C_2	655	pF
Added inductance	L_2	76	nH
Series capacitance	C_3	783	pF
Series inductance	L_3	232	nH
Matching inductance	L_4	128	nH
Matching capacitance	C_4	1023	pF

It has ON resistance of 16mΩ and the output capacitance of approximately 350pF, which is lower than calculated value for C1. The result is that we have to add the capacitors in the value of 482pF to the drain node. Input capacitance is 360pF.

IV. Realization

The class EF_2 RF power amplifier has been realized on a two layer FR-4 substrate with a relative dielectric constant of 4.3, thickness of 1.6mm and 50µm copper. The oscillator at 13.56MHz drives low side gate driver UCC27611. The RF choke inductor L is made on the toroidal core. The series inductor L3 and matching inductor L4 are integrated in one air core inductor. All the RF capacitors used are low ESR capacitors from ATC Corporation. The load is made as a combination of 50Ω/100W thick film resistors from Diconex. The gate drive signal with 30% duty cycle is given in Fig. 3. From the drain waveforms (Fig. 4 and 5.), it can be seen that ZVS is maintained with the load change.

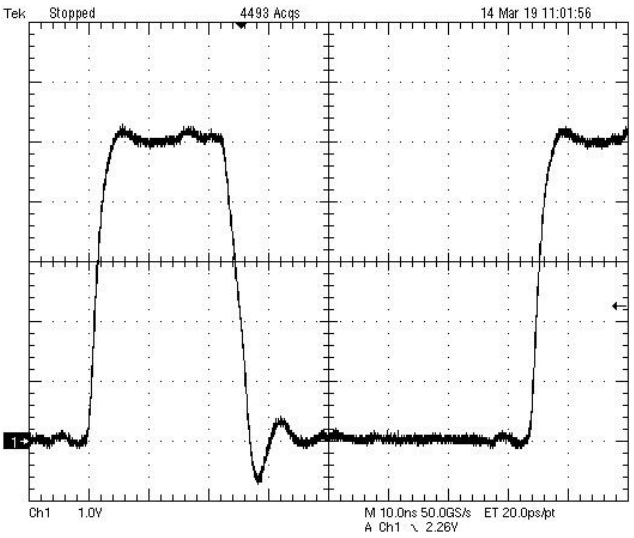

Fig. 3. Gate voltage

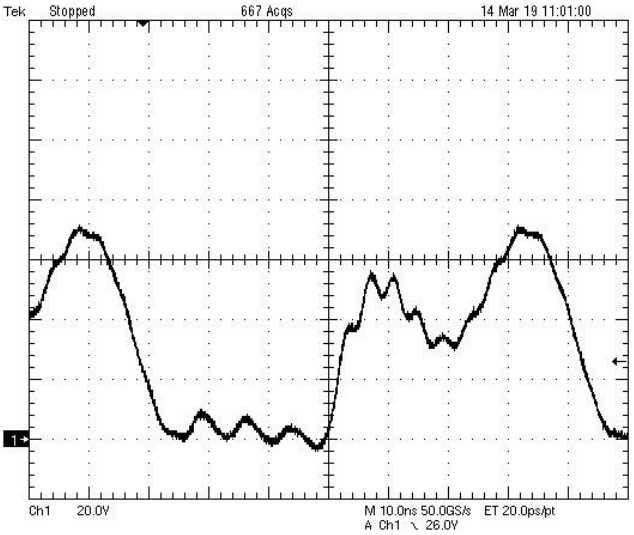

Fig. 4. Drain voltage at 50 ohm load

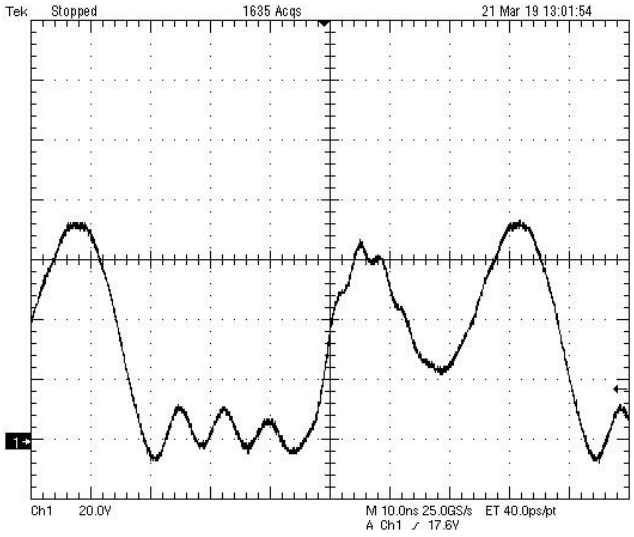

Fig. 5. Drain voltage at 100 ohm load

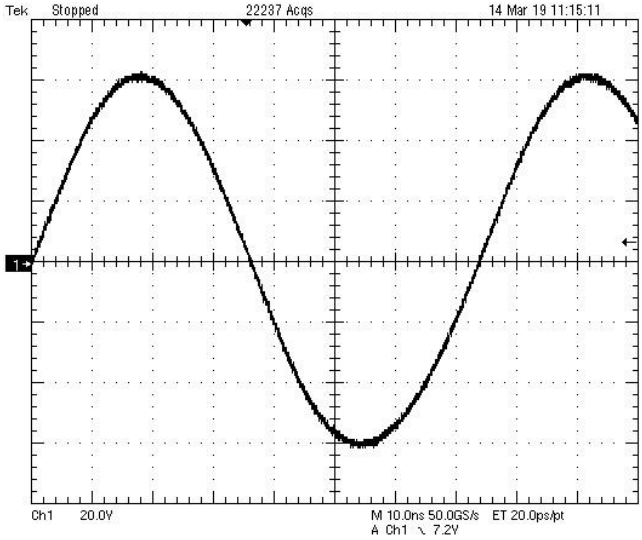

Fig. 6. Output voltage

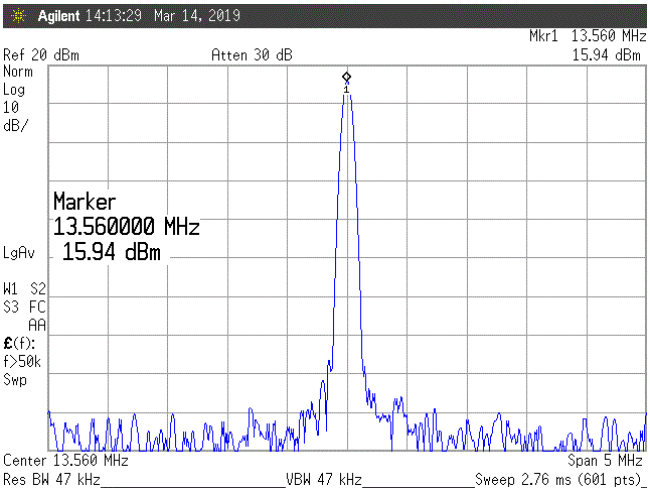

Fig. 7. Output power at fundamental frequency

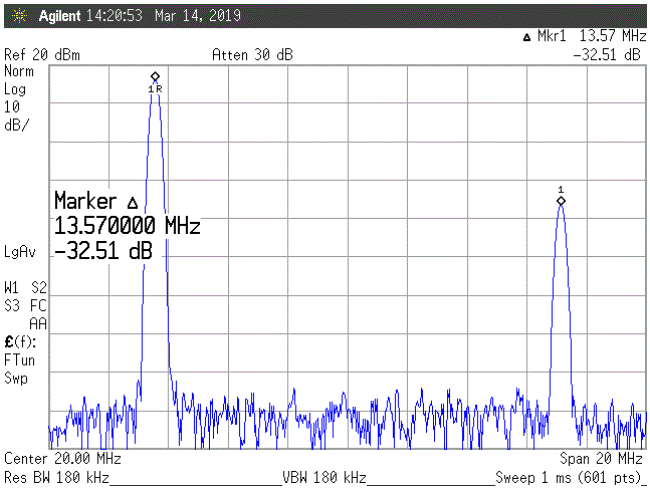

Fig. 8. Second harmonic power relative to fundamental

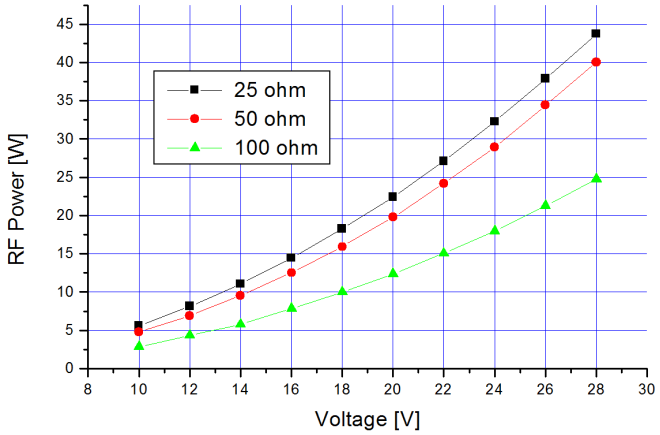

Fig. 9. Output power vs. power supply voltage

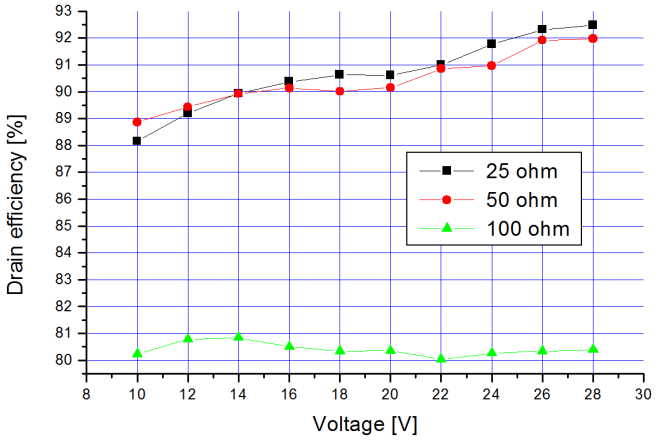

Fig. 10. Efficiency vs. power supply voltage

The peak drain voltage is slightly higher than expected because of FETs non-linear output capacitance. The output in time domain is given in Fig. 6. The output at the fundamental frequency is given in Fig. 7 (recorded with 30 dB attenuator). The second harmonic power is 32.5 dB lower relative to fundamental (Fig. 8). The output power vs. power supply voltage for various loads is given in Fig. 9.

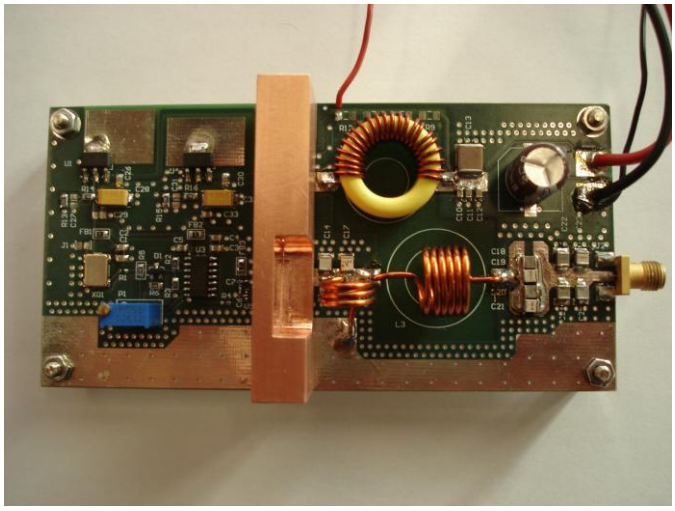

Fig. 11. Class EF_2 power amplifier prototype

Efficiency vs. power supply voltage for various loads is given in Fig. 10. It is always higher than 80% for the load change from 25 to 100 ohms. Class EF_2 power amplifier prototype is given in Fig. 11.

V. Conclusion

The class EF_2 power amplifier is designed, built and tested in the laboratory. The result verified that this amplifier can deliver safely up to 40W of RF power at 13.56 MHz into load ranging from 25 to 100 ohms. Zero voltage switching is maintained over a wide load change with efficiency from minimum 80% up to maximum over 92% unlike conventional Class E and Class EF2 who can only ensure high efficiency at fixed load.

Acknowledgment

The work is partially supported by the Serbian Ministry of Education and Science (Project III-44009). The authors would like to thank Texas Instruments for providing samples of GaN driver integrated circuits.

Measuring EMG signal with EMG click and Arduino UNO

Nemanja Peruničić, Đorđe Novaković

***Abstract*—This paper gives an insight into the basics of gathering and processing of bioelectric signals generated by our skeletal muscles. Two-part system is used as a technical solution, and the end result is shown on a computer. Signal acquisition is done with a specially designed EMG click board, and its digitization using Arduino UNO's ATmega328P microcontroller. When programming Arduino it is vital to pay attention to the hardware elements and theoretical principles on which the measurement is based; otherwise, false results will be presented – so a part of the paper is dedicated to overcoming them. The third chapter includes the complete sampling code.**

***Index Terms*—EMG signal; biceps; EMG click; Arduino.**

I. Introduction

Bioelectric recordings are of the small electrical potentials produced by the living cells and organs [1-2]. The frequencies of these signals range from 0 to 10 kHz, and their characteristics can be highly dependent on the degree of activity of the cells [3]. From a hardware standpoint EEG is the most difficult measurement to acquire [2]. Bioelectric signals are non-stationary, but their power spectrum analysis of not only provides a summary of the signal in a convenient graphic form, but also facilitates statistical analysis of signal changes that may not be evident on simple inspection of the records [1]. Besides standard methods for bioelectric signal measurement, development of methods for stochastic measurements of bioelectric signals is reported in [5-6].

Electromyography (EMG) is an electro diagnostic medicine technique for evaluating and recording the electrical activity produced by skeletal muscles. Intensity of muscle contraction is proportional to intensity of the measured signal, and it depends on the number of impulses brought by the nerves. Different muscles will generate various signals, but when it comes to humans EMG amplitude range is from 0.05 to 5 mV, and frequency from 10 to 400 Hz. As shown in [4] the vast majority of spectrum components are around 100 Hz.

We are doing non-invasive measurement, set to give valid results for signals coming from right arm biceps. Electrodes used here are disposable, made from Ag/AgCl, and designed for gel-free measurement. Each electrode is built into a hydrogel-coated adhesive foam pad that goes directly onto the skin. They connect to an ECG/EMG cable like a button – electrode's stainless steel extension is the part that lays in. Single-channel bipolar measurement is conducted, i.e. we are measuring the voltage between the pair of active electrodes located on the tendons, whilst the third one, Driven Right Leg (DRL), can be positioned anywhere on the body.

Fig. 1 shows the principle block scheme of bioelectric signal gathering system. Signal gathered by the electrodes must be amplified at least a thousand times, plus we have unwanted signals coming from other parts of the body and noises from external electro-magnetic fields. Therefore, a circuit containing amplifiers and filters is needed; in our case – EMG click. The DRL part of that circuit eliminates the common-mode voltage (utility frequency coming from the power lines; amongst others) from the input of the first amplifier to which the signal is driven (preamplifier), by inverting it and sending it back to the body.

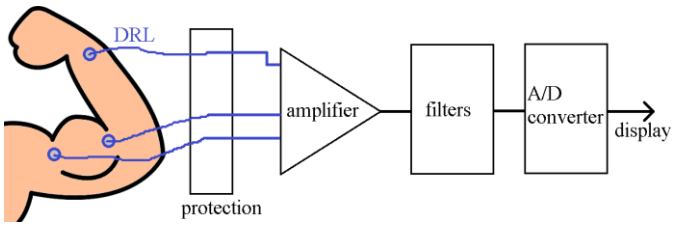

Fig. 1. Simplified block scheme of EMG acquisition device.

All of the analog filters contained within this system are RC based. Since we didn't use armored wires to connect the click board to the microcontroller there is a need for one more filter. It is a digital filter, implemented within the Arduino software.

II. Click Board

EMG click (shown on Fig. 2) serves for single-channel collection of electrical signals from motor neurons of skeletal muscles. The 3.5 mm audio jack is used to connect electrode cables to the board. The board carries two chips: MCP609 operational amplifier and MAX6106 voltage reference. Sixteen pins are located within the MCP609, out of whom three analog are used here: for the power supply (5V), ground (GND) and analog EMG signal (AN).

Nemanja Peruničić is with the Faculty of Technical Sciences, University of Novi Sad, Trg Dositeja Obradovića 6, 21000 Novi Sad, Serbia (e-mail: palatarion@yandex.com).

Đorđe Novaković is with the Faculty of Technical Sciences, University of Novi Sad, Trg Dositeja Obradovića 6, 21000 Novi Sad, Serbia (e-mail: djordjenovakovic@uns.ac.rs)

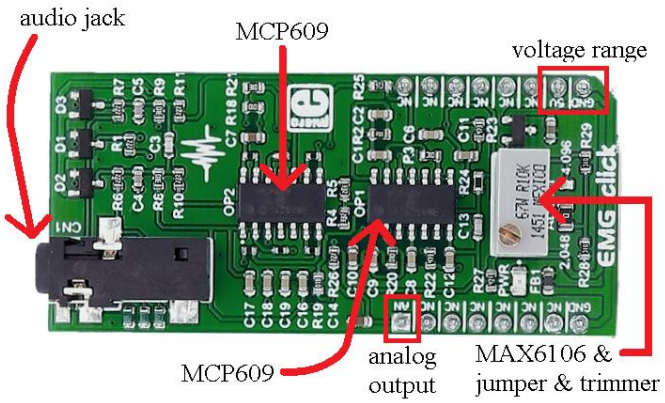

Fig. 2. EMG click board.

The differential electrode signal is run to, in order: preamplifier (instrumentation amplifier), high-pass filter, non-inverting amplifier, high-pass filter, low-pass filter, AN pin of the Arduino UNO. High-pass filters are passive first order, and separated because both need to come right after the amplifiers in order to eliminate possible signal offset. Low-pass filter is of the third order – the second order active is serial connected to the first order passive.

The DRL circuit, also a part of the MCP609, takes the signal from the input of the preamplifier and drives it through two inverters, the latter one also being a high-pass filter. Two-way zener diodes and ESD diode pairs are used as a protection for the measuring channel and the DRL electrode. The MCP609 input also contains passive low-pass filters that prevent radio waves from entering the preamplifier.

MAX6106 moves the circuit global reference mass to 2.048 V. This moves the baseline of the EMG signal up from zero – otherwise the negative values would be cut off. In case the range of the amplified EMG needs to be adjusted to another type of microcontroller, with a different input range of his A/D converter, a jumper and trimmer potentiometer are used to move the reference mass (see Fig. 3). Additionally, the non-inverting amplifier (who provides the bulk of the amplification) can be adjusted with another trimmer to accommodate new input range.

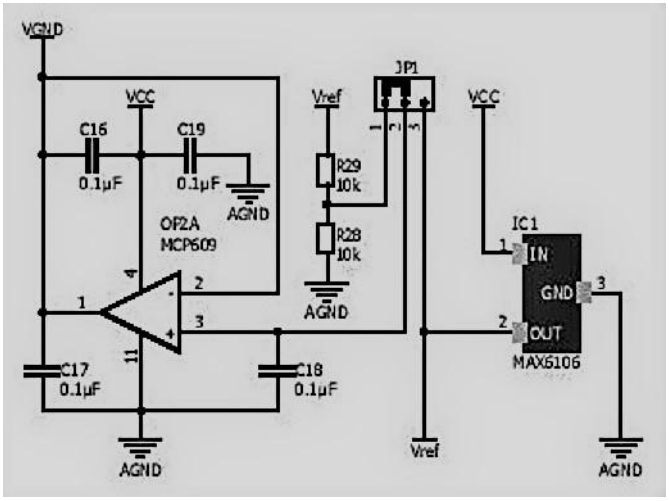

Fig. 3. Part of the click board that sets the reference mass (AGND).

EMG click gets its power supply from Arduino, who in turn is powered from the computer via USB cable.

III. Microcontroller Board

The ATmega328P microcontroller is used as a central element of the Arduino UNO board (shown on Fig. 4), which has everything needed for its support. The board contains fourteen digital input/output pins, six analog input pins, a 16 MHz crystal oscillator clock, USB 2.0 connector, power jack (if we do not want to use a computer for display) and a reset button. UNO uses another chip – ATmega16U2, for USB-to-serial conversion.

Each of the analog inputs has a 10 bit resolution (i.e. can give values from 0 to 1023), and is set to measure from ground level to 5 V; though the upper end of the range can be changed by using the AREF pin and the analogReference() function in software. The ATmega328P implements UART protocol to communicate with the computer (the speed is defined with the Serial.begin() function); it is available through digital transmit/receive pins 1 (TX) and 0 (RX). The ATmega16U2 is preprogrammed to channels the serial UART through the USB, and appears as a virtual COM port on the computer. Aside from UART, ATmega328P supports I^2C and SPI protocols.

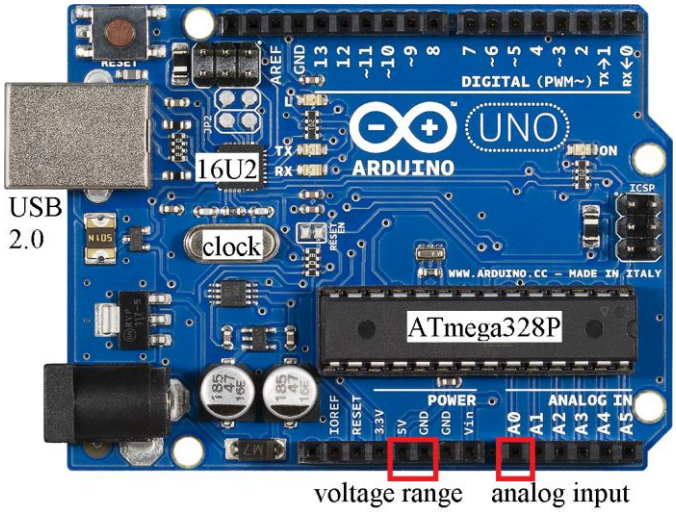

Fig. 4. Arduino UNO microcontroller board.

The Arduino software has a serial monitor which allows textual data (signal values) to be sent from the board. The two onboard LEDs connected to TX and RX pins will flash when data is being transmitted via ATmega16U2 and USB connection to the computer.

Actual pressing of the reset button is not required before an upload, because the Arduino UNO is designed to be reset by software running on a connected computer. One of the lines of the ATmega16U2 is connected to the ATmega328P's reset line with a 100 nF capacitor. When the line is asserted, the

reset line drops long enough to reset the chip. That allows the user to upload code by pressing the upload button in the Arduino software. UNO has a resettable fuse that provides an extra layer of protection for the USB port from overcurrent or shorts. If the applied current amplitude is bigger than 0.5 A, the fuse will automatically break the connection, until the overload or short is terminated.

The main purpose of the microcontroller unit is to sample the analog EMG signal coming from the click board. That can only be achieved by using its interrupt functionality. The interrupt routine is stored within the 32 KB flash program memory of the ATmega328P's CPU. The lowest addresses in the flash memory are defined as the reset and interrupt vectors. Their order determines the priority level – the lower the address the higher is the priority. RESET comes first, and we are using TIMER0_COMPA which is more than a dozen addresses higher. The interrupt vectors can be moved to the start of the boot section by setting the IVSEL bit in the CPU control register.

When an interrupt occurs the program counter will be vectored to the actual interrupt vector in order to execute its handling routine, and the corresponding interrupt flag is cleared. Interrupt flags can also be cleared by writing a logic one to the flag bit. If an interrupt conditions are met while the corresponding interrupt enable bit is cleared, the interrupt flag will be set and remembered until the interrupt is enabled, or the flag is cleared by software. Also, if interrupt condition occurs whilst the global enable bit is cleared, the corresponding interrupt flag will be set and remembered until the global enable bit is set, and will then be executed.

When the microcontroller exits an interrupt, it returns to the main program and executes one more instruction before any other pending interrupt. The cli() instruction disables interrupt immediately, and the sei() instruction enables it, although the first following instruction will be executed before any pending interrupts. The above mentioned functions are, amongst others, shown on Fig. 5.

```
int k=0, g;
volatile bool flag=false;
volatile float u;
float s;
int state=LOW;

void setup()
{
 Serial.begin(115200);
 pinMode(A0,INPUT);
 cli();
 TCCR0A = 0;
 TCCR0B = 0;
 TCNT0  = 0;
 OCR0A = 124;
 TCCR0A |= (1 << WGM01);
 TCCR0B |= (1 << CS01) | (1 << CS00);
 TIMSK0 |= (1 << OCIE0A);
 sei();
}

ISR(TIMER0_COMPA_vect){
u=(float)analogRead(A0)/1024;
flag = true;
}

void loop()
{
 while(1){
   while(k<2000){
    for(g=0, s=0; g<5; g++){
       while(!flag);
       flag = false;
       s+=u;
      }
      Serial.println(s);
      k++;
  }
  k=0;
  }
}
```

Fig. 5. Sampling instructions given to microcontroller.

The sampling frequency (*fs*) is set to 2 KHz – five times the chosen maximum frequency in our EMG signal. All five registers used inside of the setup function are 8-bit. In "clear timer on compare" (CTC) mode, which is activated with WGM01 bit, the OCR0A register is used to manipulate the counter resolution (top value) – the counter is zeroed when the counter value (TCNT0) matches the OCR0A. Output compare value is calculated as

$$OCR0A = \frac{clock}{fs \times prescale\ factor}. \qquad (1)$$

CS00 and CS01 bits set the prescaler at 64, so that the desired counter top value can fit inside the OCR0A register. All interrupts are individually masked with the timer interrupt mask register (TIMSK0), i.e. he enables the timer compare interrupt. CTC mode allows control of the compare match output frequency and simplifies the operation of counting external events.

Volatile serves to make the variable exempt from optimization by the compiler. The problem would occur when something is changed in an interrupt, while the main function tries to access the same element. The first while loop is present just to emphasize infinite repetition, it is not necessary because void loop() behaves the same on its own. Before we used registers to precisely define sampling rate, the second while loop counted 2000 samples within one second – high UART speed (115200) was used to ensure that the signal plotting happens in real-time. This loop too is unnecessary, but it does not have negative effect on code execution. ISR function enables analogRead() to take samples on 0.5 ms, but because of the for loop values will be sent to the computer every 2.5 ms, i.e. with a 400 Hz frequency. Standard UART frame length is used (10 bits; one per start and stop, and eight for the value), so the bare minimum number of needed bits per second is 4000. Since microcontroller UART module runs independently of its CPU, unnecessarily high speed is not an issue.

The noise has Gaussian distribution; mentioned in [7], so it can be filtered by arithmetic mean. When calling an interrupt, a loop is present – every five consecutive values will be averaged. Five are taken for one more reason: values coming from the A/D converter are presented in voltage quants, and it is common to display them in volts. The conversion is done by multiplying with 5 V (power supply) and dividing by 1024 (2^{10}); two fives cancel each other out. Fig. 6 shows real-time EMG signal acquisition on a serial plotter window in Arduino software. Later, if we want to show the signal on a time axis, it must be extended five times, in order to be scaled properly.

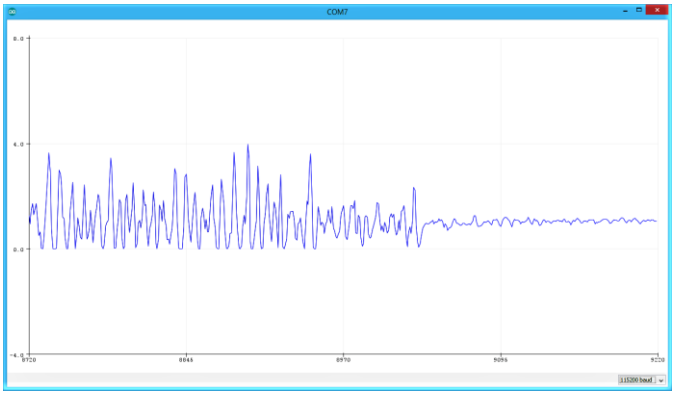

Fig. 6. Real-time EMG signal display.

IV. Conclusion

The files obtained by the Arduino serial monitor can be saved in a spreadsheet document format. From there the data can be loaded into various signal analysis programs, with tools for removing DC component and other visual disorders.

This two-part system is for academic research purposes; it is simple, relatively cheap and easy to assemble, and is a good basis for someone's further exploration of the bioelectrical signal acquisition field. Everything shown here can be translated into multi-channel measurement, and with an addition of several more auxiliary components it would give valid results for anyone's standards.

Acquisition of BCG signal by piezoelectric sensor

Jovana Jevremov, Đorđe Novaković, *Member, IEEE*, Platon Sovilj *Member, IEEE*

***Abstract*—The main idea of this paper was to construct very simple device whose function would be an acquisition of a signal obtained by piezoelectric sensor placed on a pulsating blood vessel. The measurement results were clear and unambiguous. This would enable the simple solution for tracking the number of heartbeats in a period of time. Tracking the number of heartbeats in a period of time is a wide spread functionality used by a great number of sporting aids such as smart bracelets and smart watches, as well as many click boards and even mobile applications.**

***Index Terms*— measurement and acquisition, piezoelectric sensor, ballistocardiography, heartbeat.**

I. Introduction

The main idea of this paper was to attempt to establish a link between the mechanical movement of the pulsating blood vessel and the BCG signal by using a simple piezoelectric sensor and an adaptive circuit. Based on a similar papers [1][2], a circuit was designed in order to obtain signals from a pulsating blood vessel that would be suitable for further analysis.

Piezoelectric materials have the ability to expand or shrink when exposed to voltage and generate voltage when exposed to mechanical force or pressure.

Piezoelectric ceramics and special crystals are used mainly for the production of piezoelectric sensors (in the development project described in this paper a ceramic sensor is used). [3] Ceramics consist of fine crystals. Each crystal consists of atoms with a positive or negative electric charge that are well balanced. However, the type of dielectric ceramics, ferroelectrics, have unbalanced positive and negative electrical charges in crystals, even in natural conditions, which leads to spontaneous polarization. Immediately after exposure, the ferroelectric ceramics will develop spontaneous polarization with random polar axes. As a whole, ceramics will have well balanced positive and negative electrical charges, but with the application of high DC voltage, the polar axis generating spontaneous polarization aligns in the same direction, which cannot be canceled even if the voltage is removed. The process of aligning the polar axes of spontaneous polarization is called the polarization process.

If the polarization process is applied to ferroelectric ceramics, piezoelectric ceramics are produced. When an external voltage is applied to piezoelectric ceramics, the centers of positive and negative electric charge in the ceramic are individually attracted or repelled from external electrical charges, which leads to the spread or contraction of ceramics. [4]

On the other hand, the application of pressure on piezoelectric ceramics generates positive and negative electrical charges on the surface of piezoelectric ceramics. Conversely, if a tensile force is applied to the same material, the polarity of the electrical charge will be reversed. As described above, piezoelectric ceramics allow mutual conversion of electrical energy and mechanical energy by using polarization of crystals. The property of a piezoelectric material to translate mechanical energy into electrical is called a piezoelectric effect.

The relation between the force of action on the material and the generated electric charge does not depend on the shape of the piezoelement, nor on the size, but solely on the material from which it is made. The formula for calculating the generated charge is:

$$Q = q_{11} \cdot n \cdot F \tag{1}$$

where n is the number of connected quartz elements, F force applied to the sensor, q_{11} material constant, and Q generated electric charge. [5].

II. Electrical scheme

Figure 1 shows the electrical scheme drawn in the LTspice program. [6] From left to right, the input signal can be seen as Vin, which is led to the uninverted input of the operational amplifier with a gain of 40.

The next block is a low-frequency filter that transmits frequencies below 220 Hz and then has a signal drop of -45 dB/dec. At the end there is another voltage divider with a buffer. This components aim is to add a DC component to the signal in order to raise its mean value from the zero. Voltage supply of operating amplifiers is ± 12 V.

Jovana Jevremov is with the Faculty of Technical Sciences, University of Novi Sad, Dositeja Obradovica 6, 21000 Novi Sad, Serbia (e-mail: jevremov.jovana@uns.ac.rs).

Đorđe Novaković is with the Faculty of Technical Sciences, University of Novi Sad, Dositeja Obradovica 6, 21000 Novi Sad, Serbia (e-mail: djordjenovakovic@uns.ac.rs).

Platon Sovilj is with the Faculty of Technical Sciences, University of Novi Sad, Dositeja Obradovica 6, 21000 Novi Sad, Serbia (e-mail: platon@uns.ac.rs).

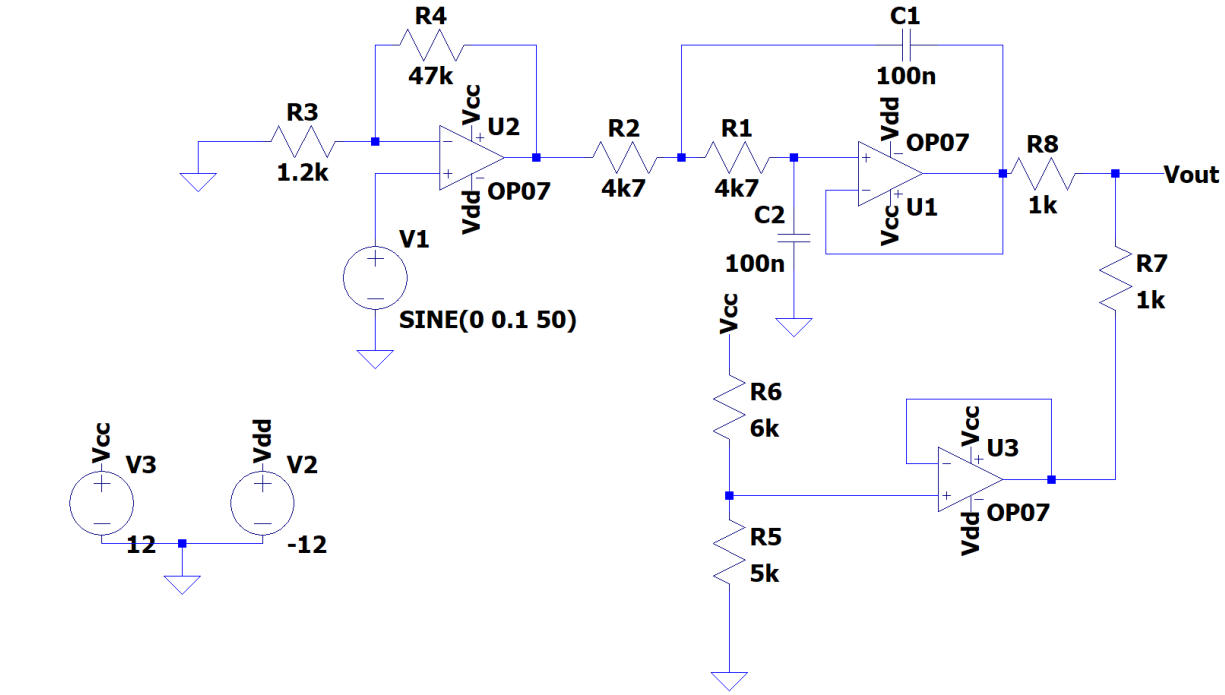

Fig. 1. Electrical scheme

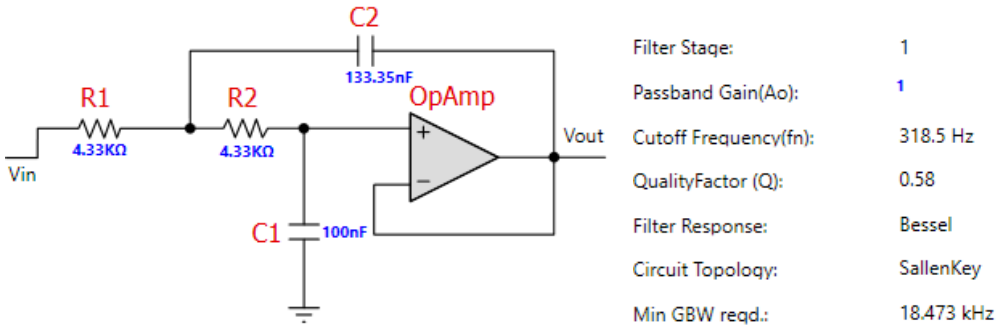

Fig. 2. Low-pass filter in FilterPro software

A. *Amplifier*

For an amplifier was chosen a non-inverting amplifier consisting of a single operational amplifier 0P07 [7] and two resistors of 47 kΩ and 1.2 kΩ. By preliminary recording of the observed signal, an oscilloscope was found its maximum amplitude of 100 mV, and therefore it was decided that the gain would be about 40 times.

B. *Low-pass filter*

The low frequency filter consists of one operational amplifier 0P07, two capacitors of 100 nF and two resistors of 4.7 kΩ. LP filtering aims to suppress high-frequency noise. The limit frequency of this filter is about 220 Hz, and then the signal is attenuated by 45 dB/dec.

The filter is designed in FilterPro, which enables the optimal solution for the parameters to be determined in a very efficient way. For the selected Sallen-Key topology, the proposed filter is given in Figure 2. Minor changes in the values of resistors and capacitors were made due to technical limitations, but topology and characteristics were retained.

C. *Offset*

To adjust the signal to an A / D converter, it was necessary to add offset to position the signal to its range. In order not to introduce additional power supplies, the existing power supply of the operational amplifiers was used, but it needed to be adjusted. A buffer block and two resistors of 1 kΩ and 1.2 kΩ represent a voltage divider that adjusts the required offset.

In Figure 3, a red signal is representing input in simulation, its amplitude is 0.1 V and frequency 50 Hz. A signal at the exit is displayed as green, amplified and raised.

Figure 4 shows how different frequency signals behave when they pass through the system. It can be noticed that the signal weakens after its frequency becomes higher than the limit.

Figure 5 shows the exact limit frequency as the spot where the signal is experiencing 3 dB attenuation.

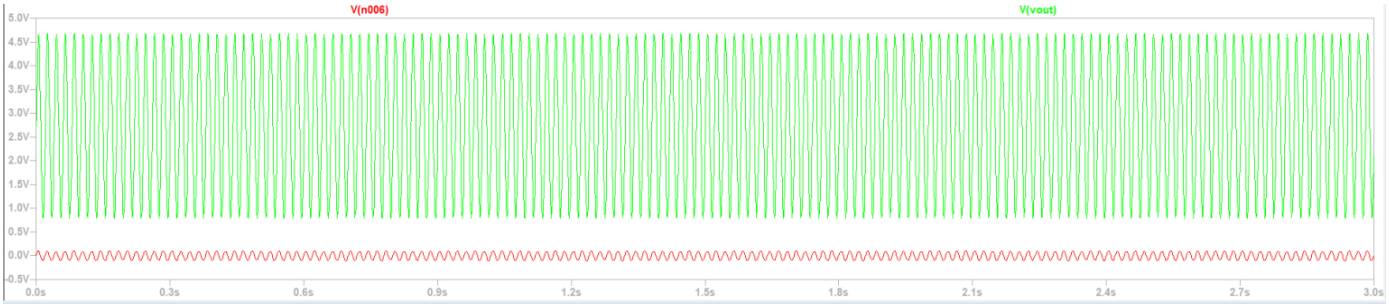

Fig. 3. Results of the transient analysis

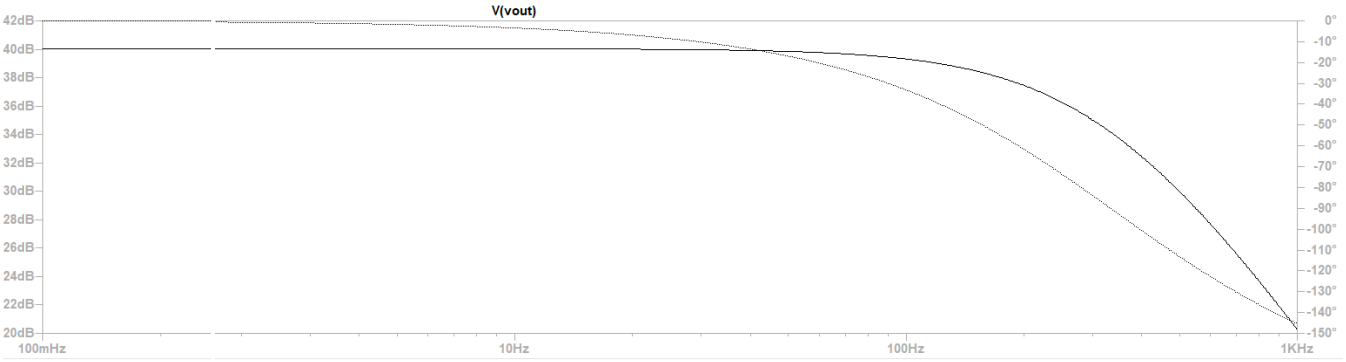

Fig. 4. Results of the AC analysis

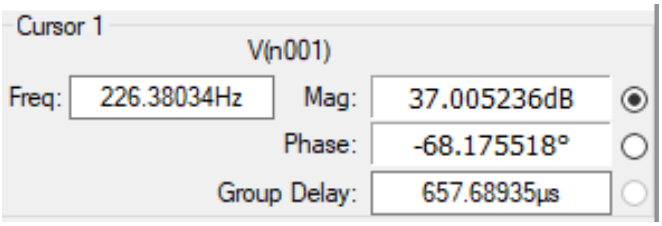

Fig. 5. Position of the cursor

III. Practical Implementation

Figure 6 shows the practical realization of the electrical scheme of Figure 1. A part of the scheme framed by a rectangle is a voltage divider with a buffer and it is adding an offset to the output signal. In the ellipse there is an amplification block, a non-inverting amplifier, and in the triangle the low-pass filter.

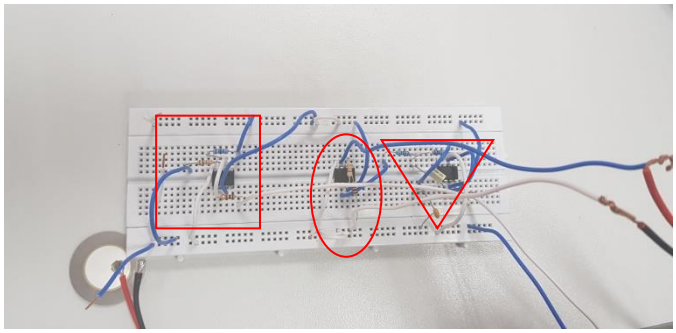

Fig. 6. Electric circuit scheme implemented on a protoboard

In addition to the highlighted parts, the sensor can also be seen in the lower left corner of the image, as well as contacts for connection with voltage +12 V, ground and voltage -12 V, along the left edge of the protoboard, respectively. On the right side of the image, there are contacts for the oscilloscope.

IV. Measurement Results

The signals recorded from the oscilloscope are preserved as a text file, and later plotted in the MATLAB. Figure 7 shows the displayed signals before and after processing. The red-colored signal represents the basic initiative obtained directly from the sensor, without any previous pre-processing.

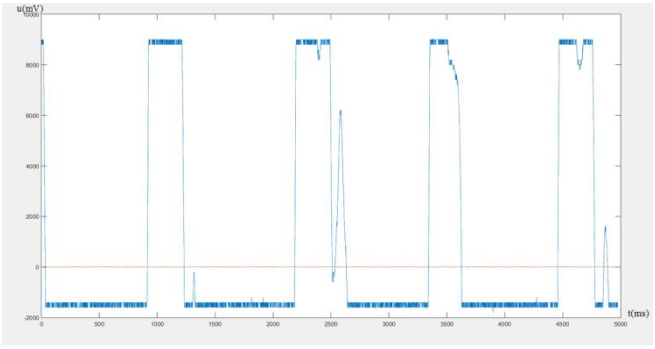

Fig. 7. Comparison of the signal from the sensor and the signal after processing

The blue signal is the same signal transmitted through the amplifier and filter system. It can be noted that the values of the original signal are very close to zero (values are of the

order mV), while the output signal is much clearer, higher values (order V) and is adjusted to further process of counting peak values of the signal.

V. Conclusion

Although it is possible to establish a connection between the contraction of individual chambers of the heart and the signals obtained by the piezoelectric sensor [2], this functionality has not been successfully demonstrated in this paper. The main problem was the hypersensitivity of the sensors and the selection of the spot of its placement on the body. On the other hand, it was shown that even though theoretical schemes cannot be performed with perfect accuracy in practice, it is possible, without significant impact on the result, to approximate the calculations. The paper presents the principle of obtaining signals from the pulsating blood vessel and its processing with the aim of determining the heart rate, but similarly, many systems used to gather signals describing other physical phenomena can be performed.

Amplifier for measurement of EMG voltage

Natalija Vukosavljević, Đorđe Novaković

***Abstract*—Measurement of low-level voltages is one of the challenges in metrology. The representatives of these voltages in biomedical measurement problems are EEG, ECG, EOG and EMG voltages. Typical approach of EMG signal measurement is measurement in a point approach. This paper proposes the design of the amplifier convenient for research system intended for measurement over an interval approach. The design is evaluated by simulation and by prototype based measurement.**

***Index Terms*—measurement; metrology; electromyography; signal conditioning.**

I. Introduction

Measurement of low-level voltages is one of the challenges in metrology. Some of the main representatives of these voltages in biomedical measurement problems are EEG (electroencephalography), ECG (electrocardiography), EOG (electrooculography) and EMG (electromiography) voltages. Electromiography is the measurement method intended for the recording of electrical activity of muscles. The advantage of electromyography is its ability to detect in vivo forces during physical activity and to quantify various pathological muscle activities. EMG signal is a nonstationary signal which can be measured by using needle electrodes or surface electrodes, the appropriate conditioning and digitizing circuits.

Standard approach of EMG signal measurement is measurement in a point approach[1]. This paper contributes with the design of the amplifier convenient for research system intended for measurement over an interval approach[2-5].

II. Model and Simulation

The designed model of theEMG amplifier consists of a protection circuit, an instrumentation amplifier, a non-inverting amplifier, a bandpass and a notch filter (Figure 1).

Fig. 1. EMG amplifier structure.

The purpose of the protection circuit (Figure 4) is to protect electrical components by limiting unwanted voltage which is a consequence of electrostatic discharge or appearance of pre-voltage.

The protection circuit consists of two resistors and of two Zener diodes connected in an anti-series way. When overvoltage appears one of Zener diodes will limit the voltage due to Zener breakdown, because of its inverse polarity, while the second diode will be directly polarized and its voltage will be 0.6 V. The chosen Zener diode has Zener breakdown for the value of voltage 4.7 V.

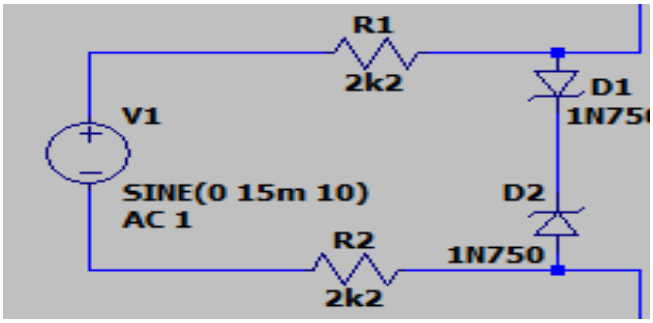

Fig. 2. Protection circuit model.

The purpose of the instrumentation amplifier is to amplify EMG signal and to eliminate common mode signal. In this design INA 122P is used, and more details about the performance of this amplifier can be found in [4].

The non-inverting amplifier (Figure 3), similar to a buffer, provides high input impedance, but also the signal amplification. This amplifier presents the second stage of amplification, and its gain is 10.

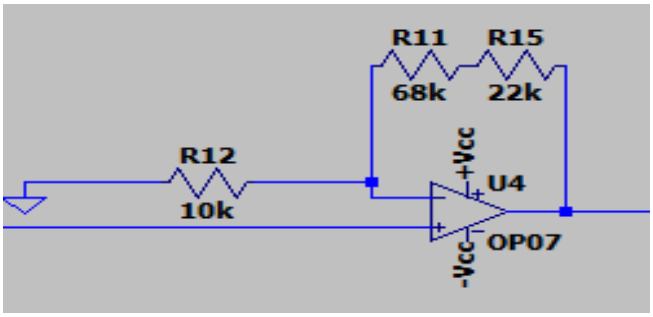

Fig. 3. The non-inverting amplifier.

A bandpass filter is obtained by connecting one active highpass filter and one active lowpass filter. The main advantage of an active filters is to isolate input from the electronic circuit, which is obtained by using operational amplifiers(OP 07).

In this implementation the bandpass filter is obtained by series connection of HP filter (cutoff frequency is 10 Hz) and LP filter (cutoff frequency is 10000 Hz). HP and LP filters are second-order filters with Butterworth design and Sallen-Key topology. The filter used in this design and its amplitude-frequency characteristic are shown in figures 4 and 6.

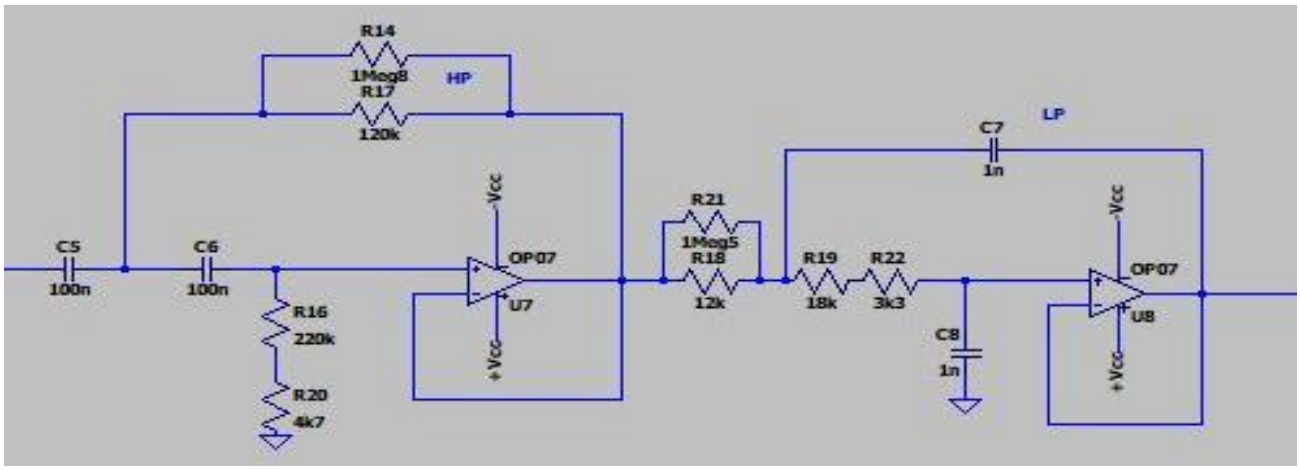

Fig. 4. Designed bandpass filter.

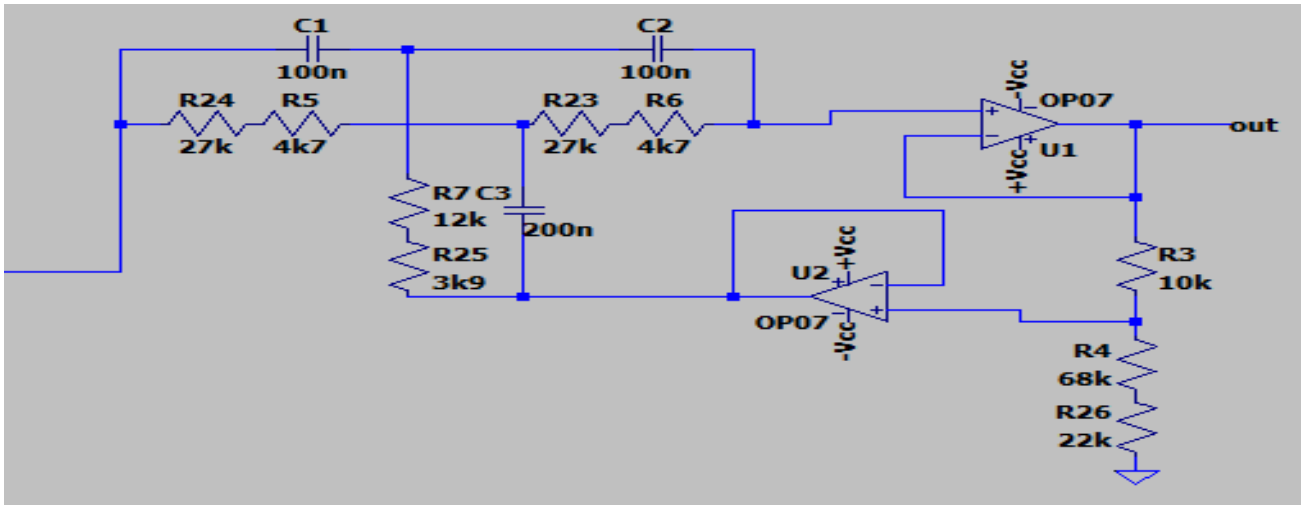

Fig.5. Active twin-t-notch filter.

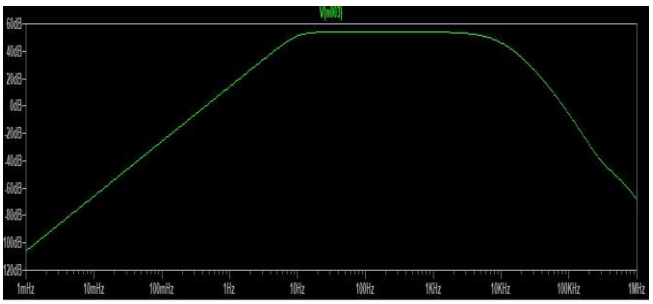

Fig. 6. The amplitude-frequency characteristic of the designed bandpass filter.

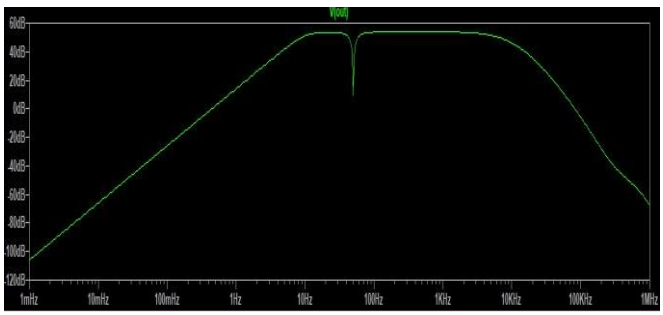

Fig.7. The amplitude frequency characteristic of an amplified signal after passing by bandpass and notch filter

The notch filter, as a special case of the bandstop filter, has the role to eliminate the line hum. It is designed as an active twin –t-notch filter (Figure 5). Amplitude -frequency characteristic after the notch and bandpass filter is shown in Figure 7.

III. PROTOTYPE AND MEASUREMENT RESULTS

Prototype is implemented on breadboard (Figure 8).

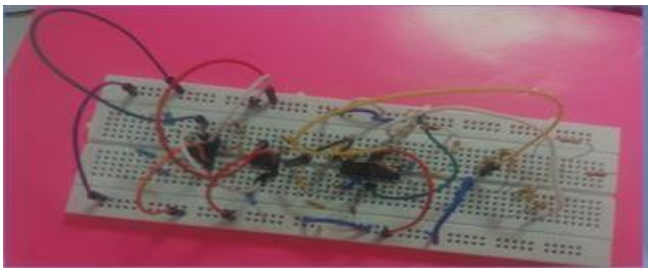

Fig.8. Prototype implementation.

The activity of muscles was measured by using surface electrodes. EMG signal measured during muscles contraction is shown at Fig. 9.

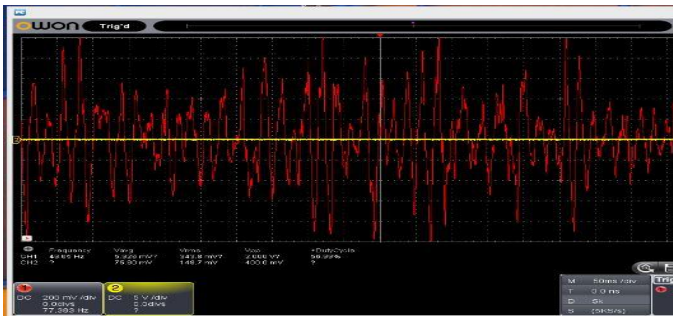

Fig. 9. EMG signal measured during muscles contraction.

IV. CONCLUSION

Typical approach of EMG signal measurement is measurement in a point approach. This paper proposes the design of the amplifier convenient for research system intended for measurement over an interval approach. The design is evaluated by simulation and by prototype based measurement. The next step is to integrate the amplifier with other circuits for measurement over an interval approach.

Analysis, circuit and firmware design for GSR signal acquisition

Rosa Ružičić, Đorđe Novaković

***Abstract*—In this paper we propose analysis and analog circuit design for GSR (galvanic skin response), microcontroller firmware used for data acquisition which communicates data to the computer via UART line for the further processing as well as the potential GSR use case.**

***Index Terms*—GSR; microcontroller; interrupt; UART; measurement.**

I. Introduction

Galvanic skin response, i.e. electrodermal activity (EDA) represents the change in skin humidity which comes as an effect to emotional stimulation. Skin humidity increases independently of whether it is happiness, sadness or any other emotion [1]. Increased skin humidity means better conductivity, that is, lower resistance we detect by connecting electrodes to the skin. Galvanic skin response finds its application in polygraph, popularly referred to as a lie detector.

II. About Galvanic Skin Response

Galvanic skin response (GSR) is one of the most sensitive measurements for emotional excitement. It comes from autonomic activation of sweat glands in the skin. Sweating happens just like an effect on our emotional state. Whenever we are emotionally excited our glands start excretion and we use GSR to detect it. Our body has about three million sweat glands. The density of sweat glands varies markedly across the body, being highest on the forehead and cheeks, the palms and fingers as well as on the sole of the feet.

Sweat secretion, blood pressure, heart rate, body temperature and a lot of other processes in our body we cannot control by consciousness. Our nervous system has two sections: sympathetic and parasympathetic nervous system. Sympathetic nervous system represents a rapid response, it activates when we are in stress situation, informally said "fight or flight". Parasympathetic nervous system represents slow response, it activates when we rest without excitement, and denotes „feeding and breeding" state.

Rosa Ružičić is with the Faculty of Technical Sciences, University of Novi Sad, Trg Dositeja Obradovića 7, 21000 Novi Sad, Serbia (e-mail: rosaruzicic@gmail.com).
Đorđe Novaković is with the Faculty of Technical Sciences, University of Novi Sad, Trg Dositeja Obradovića 7, 21000 Novi Sad, Serbia (e-mail: djordjenovakovic@uns.ac.rs).

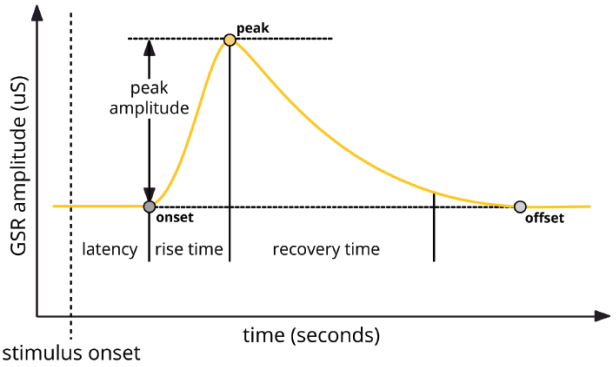

Fig. 1. GSR signal segments [2]

On the Figure 1 is shown idealized GSR signal. First part of signal (latency) includes the time duration from stimulus onset to the "GSR burst", which represents the time interval between onset and offset points in Figure 1. Peak amplitude is the GSR amplitude difference between peak and onset points. Rise time is the duration from onset to peak. Recovery time represents the duration from peak to end of "GSR burst" [3].

III. Analog circuit design

In this section, we will describe how we designed an analog circuit for GSR signal acquisition. This analog circuit is used to remove all frequencies below 0.48 Hz and above 4.8 Hz. After this step signal will be amplified by the factor of 100, then signal will be sent to the comparator, which will prepare signal for acquisition. This circuit is interesting because it detects the change in resistance. The amplitude of the signal is not of importance, we are interested in finding out whether change has happened and when its happened.

In order to build the circuit, it was necessary to draw its model. Schematic for the analog circuit was designed in LTSpice software, using model found online [2].

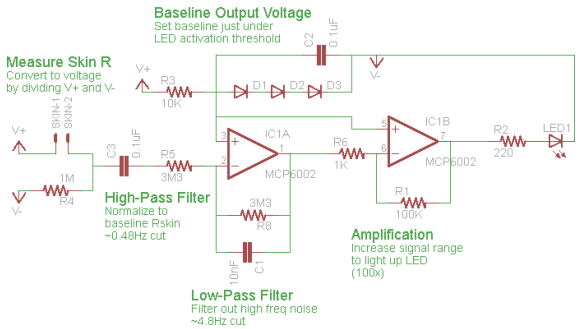

Fig. 2. Analog circuit found online

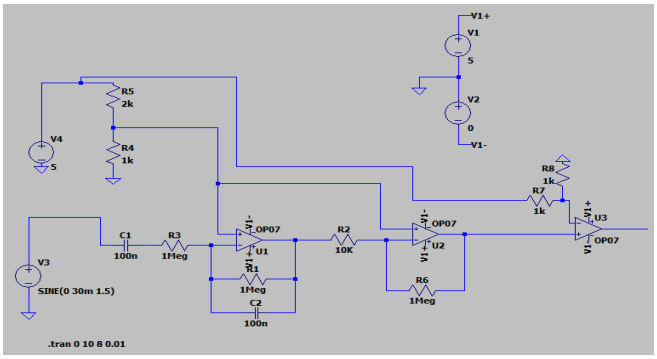

Fig. 3. LTSpice schematic

Further explained, on the input of the circuit (Figure 3) we feed AC signal, 30 mV in amplitude and of 1.5 Hz frequency. The AC signal represents measured variable skin resistance. Signal is then fed to a high-pass filter of cut-off frequency equal to 0.48 Hz. This filtered signal is sent to inverting input of a low-pass filter with cut-off frequency of 4.8 Hz, while the non-inverting input is fed with 1.6 V signal, coming from voltage divider. Amplifier‘s role is to amplify the difference of the filtered signal and the signal coming from the voltage divider, by the factor of 100. Amplified signal is then sent to a comparator, as mentioned earlier.

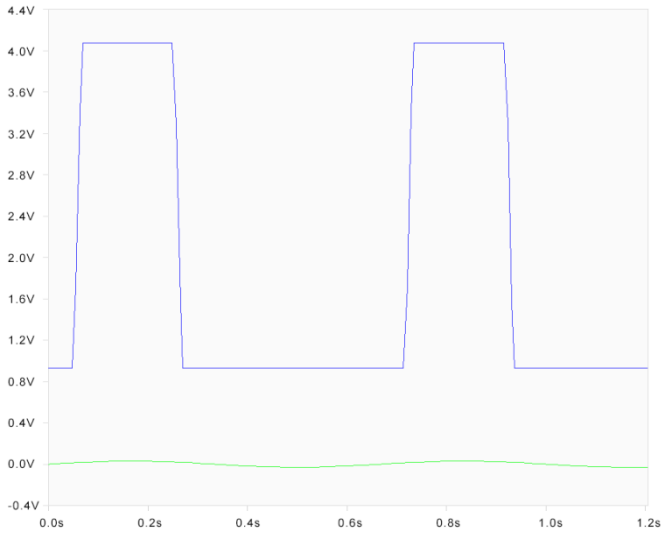

Fig.4. Circuit simulation

On the Figure 4, input signal is displayed in green while the comparator output is in blue color.

A. *Building the analog circuit*

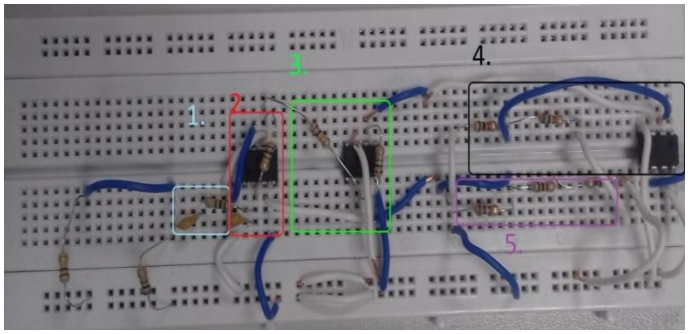

Fig. 5. Electrical circuit on protoboard.

First marked block (Figure 5) represents the high-pass filter. It consists of a C = 100 nF capacitor and a R = 1 MΩ resistor. Second marked block represents the low-pass filter, consisting of OP07 operational amplifier, R = 1 MΩ resistor and C = 100 nF capacitor which are connected in parallel and placed in a negative feedback loop of the operational amplifier. Third marked block represents amplifier consisting of OP07 and $R1$ = 10 kΩ, $R2$ = 1 MΩ resistors. Second block‘s output is fed to the inverting input of the amplifier, while the non-inverting input is fed with the fifth block‘s output.

$$A = \frac{-R2}{R1} \quad (1)$$

Fourth block represents the comparator consisting of OP07 and $R1$ = $R2$ = 1 kΩ resistors. Fifth block represents voltage divider consisting of three R = 1 kΩ resistors. The voltage is measured between the second and the third resistor of the voltage divider. The resistor in a series circuit made of the resistor and the first block is used as a reference, i.e. we use it to measure change in resistance.

B. *Simulation using oscilloscope*

The electrical circuit is supplied by +5 V DC voltage. Due to a shortage of electrodes, we used R = 10 kΩ resistor. Negative peak represents a sudden increase of resistance, while positive peak means resistance decrease (Figure 6). Interesting thing about this circuit is that it detects instant change only, after which the circuit returns to equillibrium state, i.e. it maintains constant voltage peaking 1.6 V.

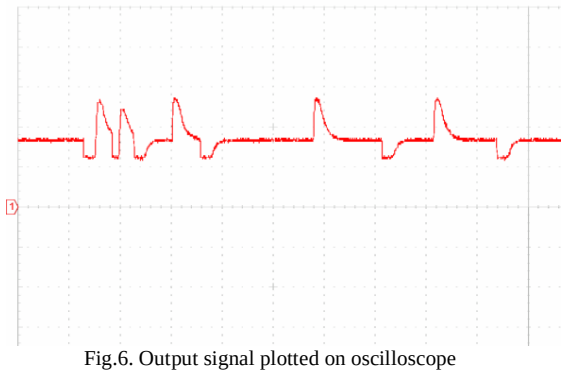

Fig.6. Output signal plotted on oscilloscope

IV. DATA ACQUISITION FIRMWARE

A. *Interrupt*

Microcontroller that we used has multiple interrupt sources and a feature which allows them to be defined as high-level or low-level priority interrupts. Events related to high-priority interrupts will intercept any lower priority interrupts that may happen in a meantime. Interrupt sources have three control bits:

1. Flag bit – Gets set when the interrupt occurs,
2. Enable bit – Enables program section execution while the flag bit is set, i.e. flag = 1,
3. Priority bit – Determines whether the bit is high or low priority. [4]

B. *UART communication*

UART (Universal asynchronous receiver/transmitter) is a computer hardware device for asynchronous serial communication in which the data format and transmission speeds are configurable. UART converts data from parallel to serial format, thus decreasing number of communication lines. Transceiver converts the parallel data into serial array of bits, while the receiver converts them back into parallel format. Two pins are used for communication, Tx and Rx, i.e. transceiver and receiver pin. UART may provide two-way communication, full duplex, which allows it to simultaneously transmit and receive data. Communication pin operates using power supply voltage levels, "1" = 5 (3, 3) V and "0" = 0 V. Easiest way to connect two microcontrollers via serial communication is to connect Tx1 to the Rx2 and Tx2 to the Rx1. It is important to define the speed of communication in order to ensure the synchronization between the transceiver and the receiver sides. Communication speed is measured in bps (bits per second) unit, and it's possible to choose among predefined values: 9600 bps, 57600 bps, 115200 bps, etc. Data package (Figure 8) starts with zero and signals the receiver side about incoming data, it's followed by the actual data and the parity bit. Parity bit is not used that often but it gets useful in applications with noisy buses. The transmitting device sets the parity bit. If the parity is set for even, the transmitting device will put a 0 in the parity bit if there is an even number of 1's in the data bits. This makes the number of 1's including the parity bit even [6]. Stop bit is always logic 0. Communication (Figure 7) is conducted via two independent lines, Tx and Rx. Data is always being transmitted in the same direction, to the computer.

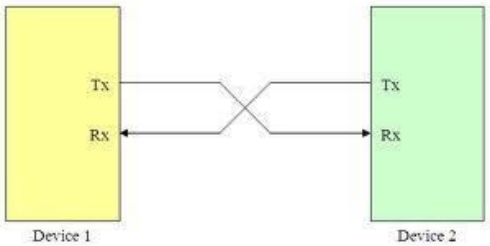

Fig. 7. Data transmission between two devices

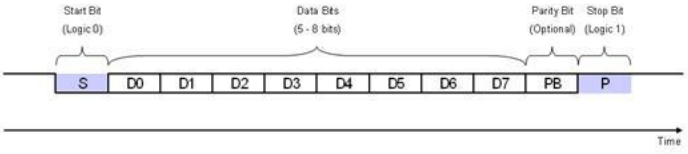

Fig. 8. Register layout

C. *Algorithm*

Firmware execution algorithm is shown in Figure 9. Program initializes variables first, then it enters super-loop, i.e. infinite loop which checks if interrupt occurred, if not, loop runs until it eventually happens. When interrupt occurs, flag is set to 0. Then it counts how many times interrupt has happened and prints change counter value in UART terminal. Figure 10 shows the execution code which runs on PIC18F45K22 microcontroller.

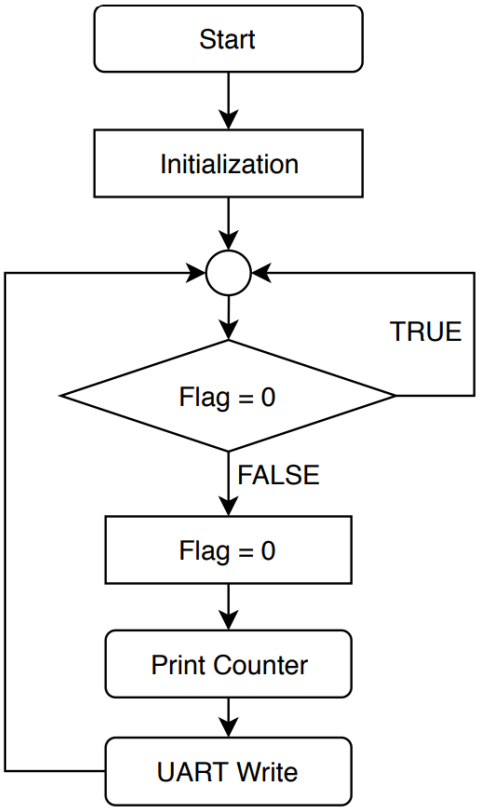

Fig. 9. Algorithm flow diagram

```
unsigned int counter = 0;
char flag;
interrupt () {
  if(INT0IF_bit) {
    INT0IF_bit = 0;
    counter++;
    flag = 1;
  }
}

static void initMain(){
  UART1_Init(9600);
  TRISB.B0 = 1;
}

void main() {
  char txt[40];

  INT0IE_bit = 1;
  GIE_bit = 1;

  // bit current_state;

  initMain();
  // current_state = 0;

  while (1) {
    while (!flag);
    flag = 0;
    sprintf(txt, "Broj promjena: %d \r\n", counter);
    UART1_Write_Text(txt);
  }
}
```

Fig. 10. Execution code, runs on PIC18F45K22 microcontroller.

V. Conclusion

We measured the changes to the skin's wetness. The effect of the increase in skin's wetness is the decrease in the resistance and we can detect change in voltage at the end of the electrical circuit. The change in resistance itself is of great importance because it shows us that there is a reaction of the human body. Then we process and amplify the signal. With a microcontroller the data is sent on the computer and the results are shown, reviewing whether change happens or not. When we connect galvanic skin response with the sphygmomanometer, heart rate monitor and breathing monitor we can make a polygraph (lie detector). Also, we can use GSR for other applications like stress level detection by using it in combination with speech [5]. In medical applications this will be very useful, because skin moisture can get a lot of information about our health. With GSR we can measure excitement levels in children with autism [1].

Acknowledgment

We would like to thank Prof. Dr. Platon Sovilj from Faculty of Technical Sciences, University of Novi Sad for his suggestion of completing this paper.

***Abstract*—The paper presents an idea of a measurement in a Fourier domain by a means stochastic digital measurement method (SDMM) as a natural and logical way to reduce the amount of big data in for processing in real time. The measurement method is explained and its application to the power and energy measurements in the power grid is briefly described.**

Keywords—Stochastic measurements, Fourier coefficients, Big Data, Signal Power.

I. Introduction

Our recent research indicates that it is possible to realize a discrete Fourier transform (DFT) processor that is capable of a fully parallel on-line computation of thousands of Fourier coefficients from an 1-bit or 2-bit array of stochastically dithered samples of the measured signal [1].

II. The Principle of Operation

The principle of operation is illustrated in Figures 1 and 2. Figure 1 shows a multiplication and accumulation (MAC) block, in which a signal f_1 (with superimposed noise n) is digitized, multiplied with a pre-stored signal f_2 and the product integrated, all within a single processor cycle. At the end of the measurement interval, division of the Counter 1 value (the integral) by the Counter 2 value (the number of samples) gives the appropriate Fourier coefficient.

Figure 2 shows a parallel processing of f_1 by $2M$ MAC blocks, thus obtaining M Fourier harmonics at the end of the measurement interval.

Every pair of coefficients (a_j, b_j) defines a signal harmonic during the measurement interval. The harmonic amplitude is an inherent harmonic descriptor for the measurement interval. The above facts have three key consequences:

1. Weierstrass approximation theorem [2] and its trigonometry polynomial are no longer relevant and are replaced by the Fourier series (integral) [3].

2. Fourier analysis is now not limited to periodic signals only, i.e. treatment of arbitrary signals becomes practically viable, and

3. There is a problem of on-line determination of the validity of a specific (a_j, b_j) pair, i.e. of a harmonic j.

Due to the consequence 1, the input signal initial value does not need to be same as the end value – these values can be arbitrary as long as they are finite. Therefore the Bernstein polynomials [4] as well as generic polynomial approximations become much less relevant.

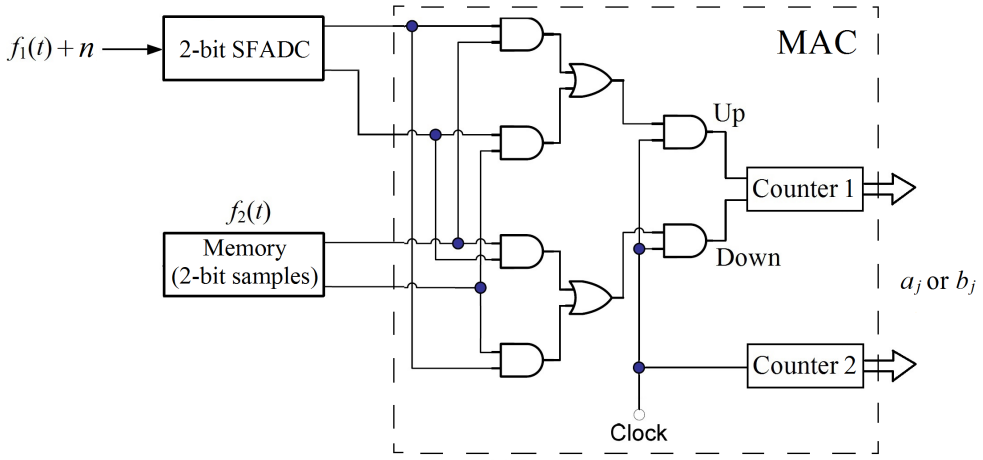

Fig. 1. An optimal scheme for measuring a single Fourier coefficient with a two-bit stochastic flash A/D converter.

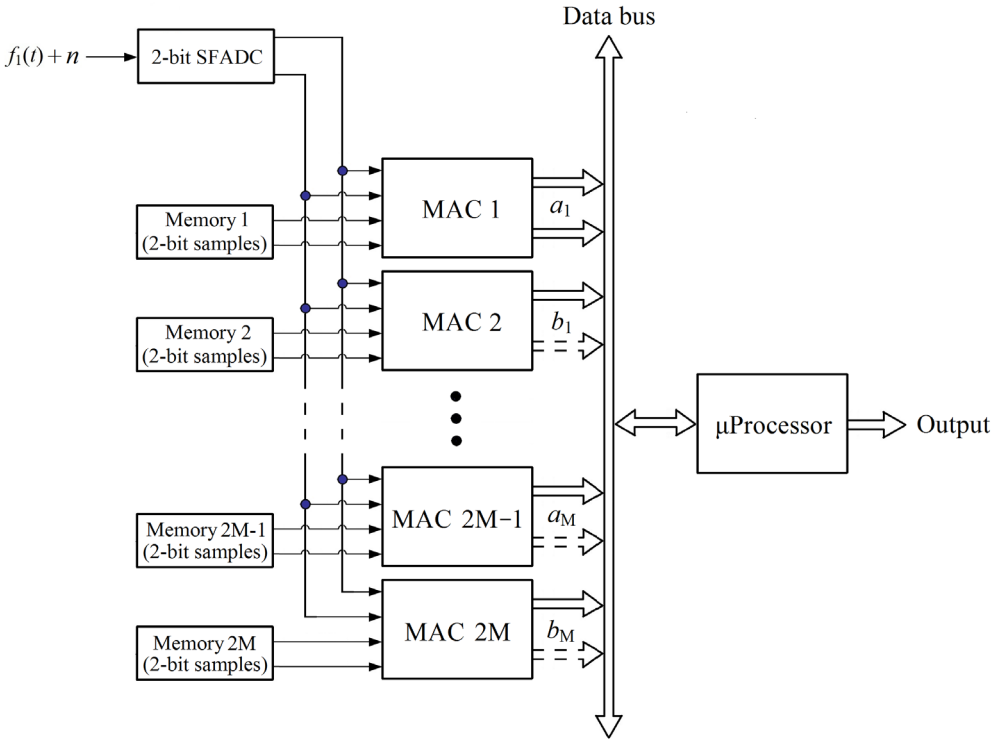

Fig. 2. A stochastic DFT processor for measuring 2*M* Fourier coefficients.

The Consequence 2 enables analysis of any continuous signal with a finite number of first-order discontinuities, via piece-wise analyses, on an arbitrary time interval [3].

The Consequence 3 indicates that an efficient and smart algorithm to quickly estimate the validity of a specific (*aj*, *bj*) pair is needed. Such an algorithm can be developed on the basis of a detailed insight into the hardware structure of the presented DFT processor. It features a simple and robust design, as well as accuracy, precision and speed [5]-[8]. The performance of first versions of such an algorithm is promising and encouraging.

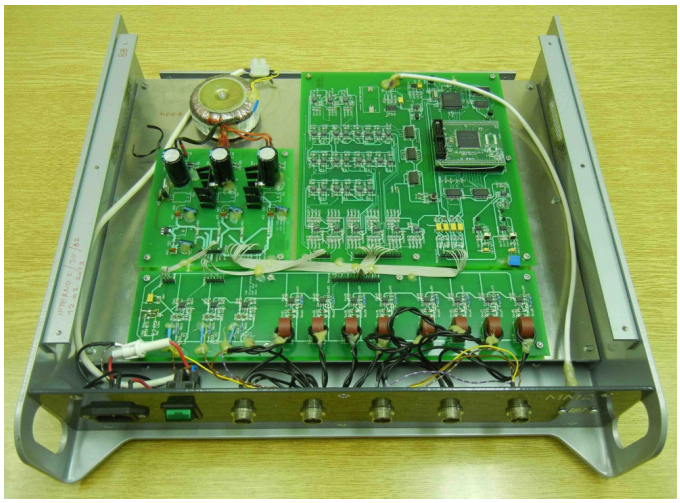

Fig. 3. A two-bit double three-phase power analyzer implemented in FPGA technology.

If such a device entailing (1-bit or 2-bit A/D converter with DFT processor and fast estimator of harmonic's validity) is to be used for processing of big data, it is natural to process and store only the important data. This means that overall volume of processing as well as memory needs to be minimised. This is not the only benefit of the proposed approach/method. The Fourier coefficients in the DFT processors, shown in Figure 2, are calculated in counters that have an inherent pipelining feature and do not suffer from carry propagation problems [9]. This can enable high data processing speeds. It is possible, therefore, to design a custom processor, tailored for the described use. The use of FPGA [10] offer many possibilities for the implementation of both prototypes, as well as a batch production. Some additional Internet of Things requirements, such as monitoring and control of household [11], may justify the use of ASIC implementations.

It should be noted that a single datum that is a measure of the observed signal (for processing and/or storage) is not a real number any more. A quantum of signal information is dominantly a complex number in a frequency domain that also contains information on its validity over the observation time interval. A finite set of such data that include the "validity" faithfully describe the signal spectrum over the measurement interval.

Signal reconstruction and/or further processing of such data is not a problem, because the equivalency of time domain and frequency (Fourier) domain is well known. The Inverse Fast Fourier Transformation (IFFT) implemented in a large number of software tools can be utilised for transition from Fourier to time domain. Our research has confirmed that use of FPGA

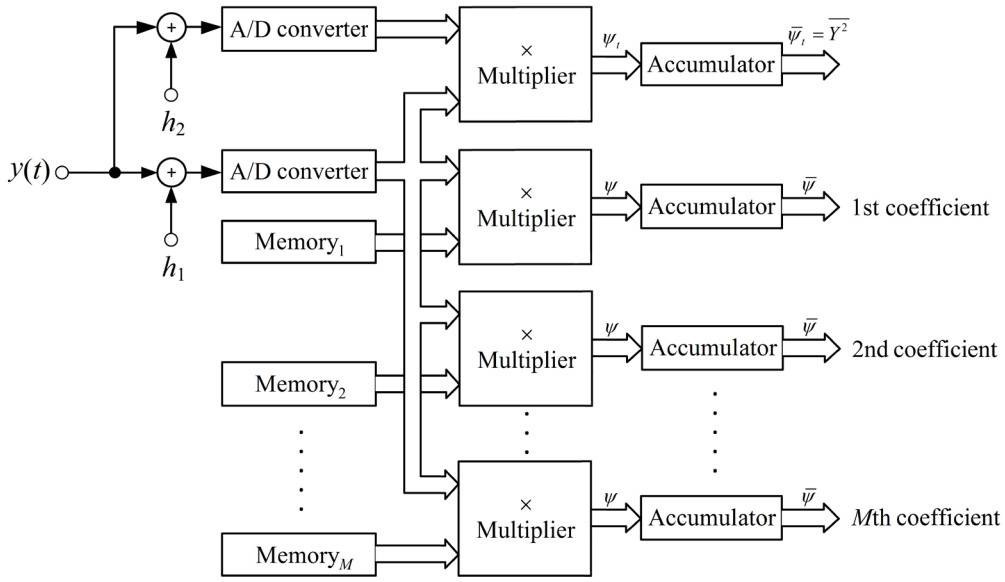

Fig. 4. A hardware scheme for on-line determination of the validity of a specific (a_j, b_j) pair, i.e. of a harmonic j.

technology enables fast and efficient experimental validation of the new approaches proposed here. Based on it, powerful measurement devices, such as the three-phase analyser and energy meter shown in Figure 3, have been developed.

Several additional fine details need to be further explored in this synergic frequency-time treatment of signal measurement and processing to make it equally efficient in both domains. We need to find answers to the following questions:

a. an optimal number of significant harmonics,
b. optimal sampling frequency of the reconstructed signal,
c. an acceptable number/size of first-order discontinuities,
d. an optimal length of the measurement interval,
e. an optimal precision of the reconstruction, etc.

The main goal of the paper is to define a role for SDDM methodology in the reduction of the volume Big Data (BD) that is independent from the BD generator, which leads to the need for a standard sampling method. The underlying motivation is based on the fact that SDDFT output can process data in real time and immediately provide naturally weighted components. In other words, non-critical results can be immediately discarded and only the critical ones are stored.

As an example of defining a specific problem and finding its optimal solution, let us consider case a): the uppermost channel in the instrument shown in Figure 4 measures the average signal power over the measurement time interval. Other channels shown in Figure 4 measure M Fourier coefficients over the same time interval. When all the coefficients are squared and then sorted in a descending order, they represent the average signal power. It is possible to approximately calculate, within a pre-defined accuracy, the average signal power by including only K ($K < M/2$) most significant harmonics. The optimisation criterion is to determine the lowest number of harmonics that satisfy the prescribed accuracy level. This criterion is common in measuring power and energy in a power grid. Similarly, problems denoted under b), c), d), e) require a clear initial brief definition in order to reach a solution. These are currently under research.

III. Conclusion

The paper presented the principle of operation of a novel approach to reducing the big data volume by means of a stochastic digital measurement method. This can be achieved by measuring harmonics that are naturally weighted, which opens a possibility to determine harmonics' validity in real time, before further processing and/or storage. This is not possible to do in time domain with data that can be obtained using the standard sampling method approach.

This novel approach opens up an array of new but solvable problems. One of these – determining an optimal number of harmonics needed in power measurements – is solved and described in the paper. The use of FPGA technology offered a great possibility for implementation and an efficient experimental verification.

The important characteristics of harmonics measurements are the adaptive precision and high accuracy, stemming from the elimination of systemic errors in hardware. Since the measurement results obtained by the proposed approach depends on the signal waveform, a further research effort will be invested in the development of applications for specific signal classes.

The use of IFFT provides simple and fast transition from frequency to the time domain – especially when a small number of significant harmonics is involved – thus enabling the use of a number of software solutions tailored for time-domain processing.

LabVIEW-Arduino UNO Temperature Measuring System

Josif Tomić, *Member, IEEE*, Miodrag Kušljević, Platon Sovilj, *Member, IEEE*, Vladimir Rajs, *Member, IEEE*

***Abstract*—Today's modern measuring technique is based on the implementation of microprocessor-supported measurement and information systems. The low price of computing and electronic components has led to measuring devices becoming software-oriented. The main emphasis is placed on the realization of complex mathematical algorithms, over sampled physical signals that were converted into electricity or voltage. The same case applies to temperature measurements. The temperature is undoubtedly the most widely measured physical size and there is a very large number of measuring methods and sensors that can precisely measure this size. Unfortunately, many temperature sensors have non-linear characteristics, so complex numerical formulas need to be applied to get the exact values. This paper presents a microprocessor measuring device for measuring and calibrating temperature sensors from silicon. The system is characterized by simplicity, low price and satisfactory accuracy. The device was realized with the Arduino UNO card and the program is written in the LabVIEW software package, using the LIFA library of functions.**

***Index Terms*—Temperature; Arduino UNO; LabVIEW; LIFA; Silicon temperature sensors.**

I. Introduction

Temperature is without doubt the most widely measured variable. Temperature is a measure of molecular energy, or heat energy, and the potential to transfer heat energy. Thermometers can be traced back to Galileo (1595). In the process control of chemical reactions, temperature control is of major importance, since chemical reactions are temperature-dependent. It is therefore necessary, in most cases, to measure the temperature together with the physical size, so that certain mathematical corrections can be made to achieve precise measurements.

II. Temperature Sensors

Because of the high importance of temperature information, there are a very large number of sensors and measurement methods for temperature measurement. Temperature sensors could be divided into two large groups: contact and noncontact sensors [1, 2].

Josif Tomić - Faculty of Technical Sciences, University of Novi Sad, Trg Dositeja Obradovića 6, Novi Sad 21000, Serbia (e-mail: tomicj@uns.ac.rs).

Miodrag Kušljević – Termoelektro Enel AD,Uralska 9, Beograd 11060, Serbia (e-mail: miodrag.kusljevic@te-enel.rs).

Platon Sovilj – Faculty of Technical Sciences, University of Novi Sad, Trg Dositeja Obradovića 6, Novi Sad 21000, Serbia (e-mail: platon@uns.ac.rs).

Vladimir Rajs – Faculty of Technical Sciences, University of Novi Sad, Trg Dositeja Obradovića 6, Novi Sad 21000, Serbia (e-mail: vladimir@uns.ac.rs).

Noncontact temperature sensors (infrared), work mostly on the optical principle and measurement is based on the ability of all materials to emit electromagnetic radiation (infrared radiation). This radiation comes from the motion of charged particles in the atom. All matter at a temperature greater than absolute zero emits heat radiation. Infrared measuring instruments use this radiation to determine the body temperature. When a body is heated, it radiates the electromagnetic energy of different wavelengths. The advantages of contactless temperature measurements are: a) the measurement time is very short (milliseconds), b) it is possible to measure the temperature on the moving objects, and c) measurements can be performed in hazardous and physically inaccessible locations (high voltage, large distance). These devices measure without problems temperatures in the range of 1300°C to 3000°C, where contact thermometers cannot be used or have a limited lifetime. Also, energy is not taken from the measurement object so that the measurements are much more accurate.

There are several groups of contact sensors for temperature measurement, and the main groups are: a) resistance temperature detectors, b) thermistors, c) thermocouples, and d) silicon-based temperature sensors.

Platinum Resistance Temperature Detectors are characterized by a very high accuracy and precision of temperature measuring of 0.1%, in the range of -200°C to 850°C. They need to be used in conjunction with XTR1xx conditioners from Burr-Brown. They give a current excitation to the sensor, amplify and linearize the output signal. These sensors are characterized by high consistency and repeatability of measurement. Unfortunately, they also have a higher price than other temperature sensors. The Pt-100 temperature-dependent resistors have a resistance of 100Ω at a temperature of 0°C and a resistance of 138.4Ω at a temperature of 100°C. Temperature change of 1°C gives a resistance variation of 0.384Ω. Also, there are sensors with a resistance of 1000Ω at a temperature of 0°C and they have a Pt-1000 label. For these sensors, the dependence between temperature and resistance changes is mostly linear, in a low temperature range, typically between 0° C and 100° C. For accurate measurements in a wider temperature range, it is necessary to use the following equation:

$$R_T = R_0 \times (1 + A \times T + B \times T^2 + C \times T^3) \quad (1)$$

Where the coefficients R_0, A, B and C are: R_0=100Ω, A=3.9083×10^{-3} C^{-1}, B=-5.775×10^{-7} C^{-2}, C=-4.183×10^{-12} C^{-3}, bellow 0°C or C = 0, above 0°C.

Thermocouples are formed when two dissimilar metals are joined together to form a junction. A current will flow in the circuit if the two junctions are at different temperatures. The current flowing is the result of the difference in electromotive force developed at the two junctions due to their temperature difference. The voltage difference between the two junctions is measured, and this difference is proportional to the temperature. This phenomenon was discovered in 1821 by Thomas Johann Seebeck. The advantages are: low cost, simple construction, high robustness, wide temperature range (-200°C to 3000°C), short response time, good accuracy and repeatability for rough measurements (+/-2%). Their disadvantages are: low sensitivity (50μV/°C), high sensitivity to noise and insufficient accuracy for precise measurements, great nonlinearity, limited work life and definition of cold junction point. A formula that defines the dependence voltage of temperature is:

$$\nabla V = -S(T)\nabla T \tag{2}$$

Where *S(T)* is a temperature-dependent material property known as the Seebeck coefficient.

Thermistor is an element (most often a metal oxide) which, when changing temperature, changes its resistance. The temperature coefficient may be both positive (PTC) and negative (NTC), and may have a resistance variation of 10% by degrees Celsius. It is used in applications where it is necessary to detect small changes in temperature, for example, only 0.01°C. The accuracy of the thermistor is approximately ten times greater than the accuracy of the thermocouple. The formula for NTC resistors is as follows:

$$R_{NTC}=R_0 \times e^{(B/T)} \tag{3}$$

Where R_0 is the resistance at the reference temperature and B is a constant which depends on the material from which the thermistor was made. Similar formula applies to PTC resistors:

$$R_{PTC}= A + C \times e^{(B/T)} \tag{4}$$

Only the platinum RTD can have better accuracy from the thermistor. The advantages of a thermistor are small physical dimensions and high nominal resistance. Small dimensions contribute to quick response, and high resistance reduces the impact of terminal resistance. Thermistors are very non-linear and have the most common logarithmic characteristic of the third order. Thermistors can be used in a temperature range of -50°C to 100°C. Thermistors are also very sensitive to strike.

Silicon temperature sensors are devices made in much the same way as transistors and integrated circuits. A primary physical property of silicon-based temperature sensors is their extreme stability over time and over extreme environmental conditions. This is because silicon is an inherently stable element, especially in its crystalline form. The crystal structure that makes up a silicon-based temperature sensor is literally *rock-solid*. Another important consideration of these types of sensors is they are fabricated using highly repeatable manufacturing processes, using fully automatic machinery and photolithographic techniques.

Measurements made with silicon-based sensors are highly consistent and very stable, which translates to low drift in the accuracy of readings over time. In comparison with traditional temperature monitoring devices, silicon-based sensors lead to high-performance over the lifetime of the product in which they are used.

One of the most prominent silicon sensors is the KTY temperature detector, manufactured by Philips. There are a whole series of these sensors that differ in their characteristics. The formula by which the temperature resistance is calculated is:

$$R_T= R_0 \times (1+A \times T+B \times T^2) \tag{5}$$

Where R_0 is the resistance at the reference temperature, and A, B are the polynomial constants.

When high accuracy or wide measurement range is required, the temperature sensor parameters are not used from the table given by the manufacturer. This applies to all temperature sensors. The reason for this is a large error in measuring the temperature, which can be even ±20%. Therefore, individual calibration is necessary. Detailed calibration is not done by the manufacturer, as it would significantly raise the price of the temperature sensors. Calibration is done in a number of points and then numerically computes the formula by which the values of all temperatures can be obtained. This formula is most commonly of the higher order polynomial. The calibration quality depends on the precision of the reference thermometer and the mathematical algorithm used to make the curve fit. The calibration is based on several models. Most commonly, this is the *General Least Square* algorithm based on *Least Mean Squares (LMS)* algorithms or some of the exponential algorithms.

III. ARDUINO - OVERVIEW

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programed a microcontroller and a ready-made software called Arduino IDE (*Integrated Development Environment*), which is used to write and upload the computer code to the physical board [3]. This software package is completely free and can be downloaded from the Internet at the address: https://www.arduino.cc/en/Main/Software. The key features of this board are: a) Arduino board is able to read analog or read/write digital signals, b) Arduino board can send a set of instructions to the microcontroller via Arduino IDE and USB cable, c) Arduino does not need an extra piece of hardware (called a boot loader) in order to load a new code onto the board, d) Arduino IDE uses a simplified version of C++, making it easier to learn to program, e) Arduino board can change the firmware to match another programming language, f) it has a very low price, about 12 €, g) it has

embedded I2C, SPI and RS232 communications, h) it has a large number of hardware add-ons for Internet and Wi-Fi communication.

The heart of Arduino UNO board is high performance, low power, RISC, Atmel AVR 8-Bit processor ATmega328, whose characteristics are: a) operating voltage of 5V, b) 131 powerful instructions, c) 16 MHz clock speed, d) 32KB flash program memory, e) 2KB SRAM, f) 1KB EEPROM, g) two 8-bit timer/counters, h) 6-PWM channels, i) 6-channel 10-bit AD converter, j) programmable serial Interface, k) 23 programmable I/O pins. The look of the Arduino UNO board is shown in Figure 1.

Fig. 1. Arduino UNO board

Lately due to the enormous popularity of the LabVIEW software package, a large number of companies create many toolkits for a variety of hardware and software interfaces. All these tools are available from the Internet site: http://www.ni.com/gate/gb/GB_EVALTLKTLVARDIO/US

As this site is continuously updated it is possible to get a list of all the available interfaces. *LabVIEW VI Package Manager* can also be accessed directly from the site: http://jki.net/vipm. These programs are in general free of charge. Most importantly, Arduino board can be programmed using only LabVIEW graphical language. In the implementation of this measuring device, the LIFA (*LabVIEW Interfaces For Arduino*) program library was used so that the entire program was realized in the LabVIEW program package. This open source toolkit is made for users to create custom programs for their sensors. In order for the Arduino card to accept LabVIEW programs it is necessary to download the *LIFA_base* firmware program, using the Arduino IDE interface [4]. This is a great relief for engineers because they do not have to write a program in two programming languages (C and LabVIEW) and it is significantly easier to test the whole program. This practically means that is possible to programming *embedded* microprocessor devices with graphical language. After writing and testing the LabVIEW program it is necessary to download program to Arduino board using a USB port. This is the process of finalizing the program, and it is only necessary to disconnect the card from the computer and plug in 9V power supply.

The LIFA software function palette automatically appears in the LabVIEW program (if the installation is done correctly) and includes a large number of functions. Some of them are at a very low level and allow access to individual pins on the Arduino card, while other functions are complete programs for measuring and acquisition signals from different types of sensors. Figure 2. shows the finished program for reading analogue values from one AD converter input.

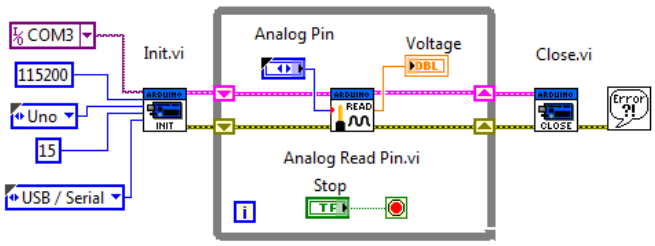

Fig. 2. Realization of LabVIEW program with LIFA interface functions

IV. Realization of Measuring System

The temperature measurement process with the silicone sensor KTY81-121 is made in the following order.

At first, calibration of the sensor is carried out by selecting the temperature range in which the unknown resistance of the sensor will be measured. The maximum temperature range is from -50°C to + 150°C. The desired temperature range needs to be divided into several parts, for example, with a step of 10°C. It is now necessary to measure the resistance of the sensor in these temperature values with a precision ohm-meter. In this way, a table is formed, which contains the values of temperature and resistance. The front panel of the finished program is shown in Figure 3. The measured values can be seen in the table on the left side of the front panel. Using the values from the table, the coefficients of the polynomial are now calculated using the method of the *Least Mean Squares* [5, 6]. As a result of this mathematical operation, *Polynomial Coefficients* are obtained, whose values are displayed on the front panel, at the right side. It can be seen that it is obtained a polynomial of a very large order. The front panel shows the graphically-fitted curve as well as the modified values of the resistance of the temperature sensor at the given temperatures. Residue returns the weighted average error of the fitted model. It seems that the fitting curve was successfully done with a very small *Mean Square Error*, *mse*=2.844. The second part of the program performs temperature measurement and is made using LIFA functions. At first, LIFA functions take the numerical value from the AD converter and calculate mathematically the resistance. The acquired resistance value is entered in the polynomial and using numerical algorithm the value of the current temperature is obtained. This value is then displayed on the front panel in numerical and graphic form.

The realized measuring device is very sensitive, so it is necessary to provide precise reference voltage for the AD converter as well as precision measuring equipment for calibration. This measuring device has a very high accuracy and precision of temperature measurement. The temperature measurement error does not exceed +/- 0.1°C throughout the measuring range, which is a very good value for this type of sensors. For high precision, sensor calibration should be performed once a year.

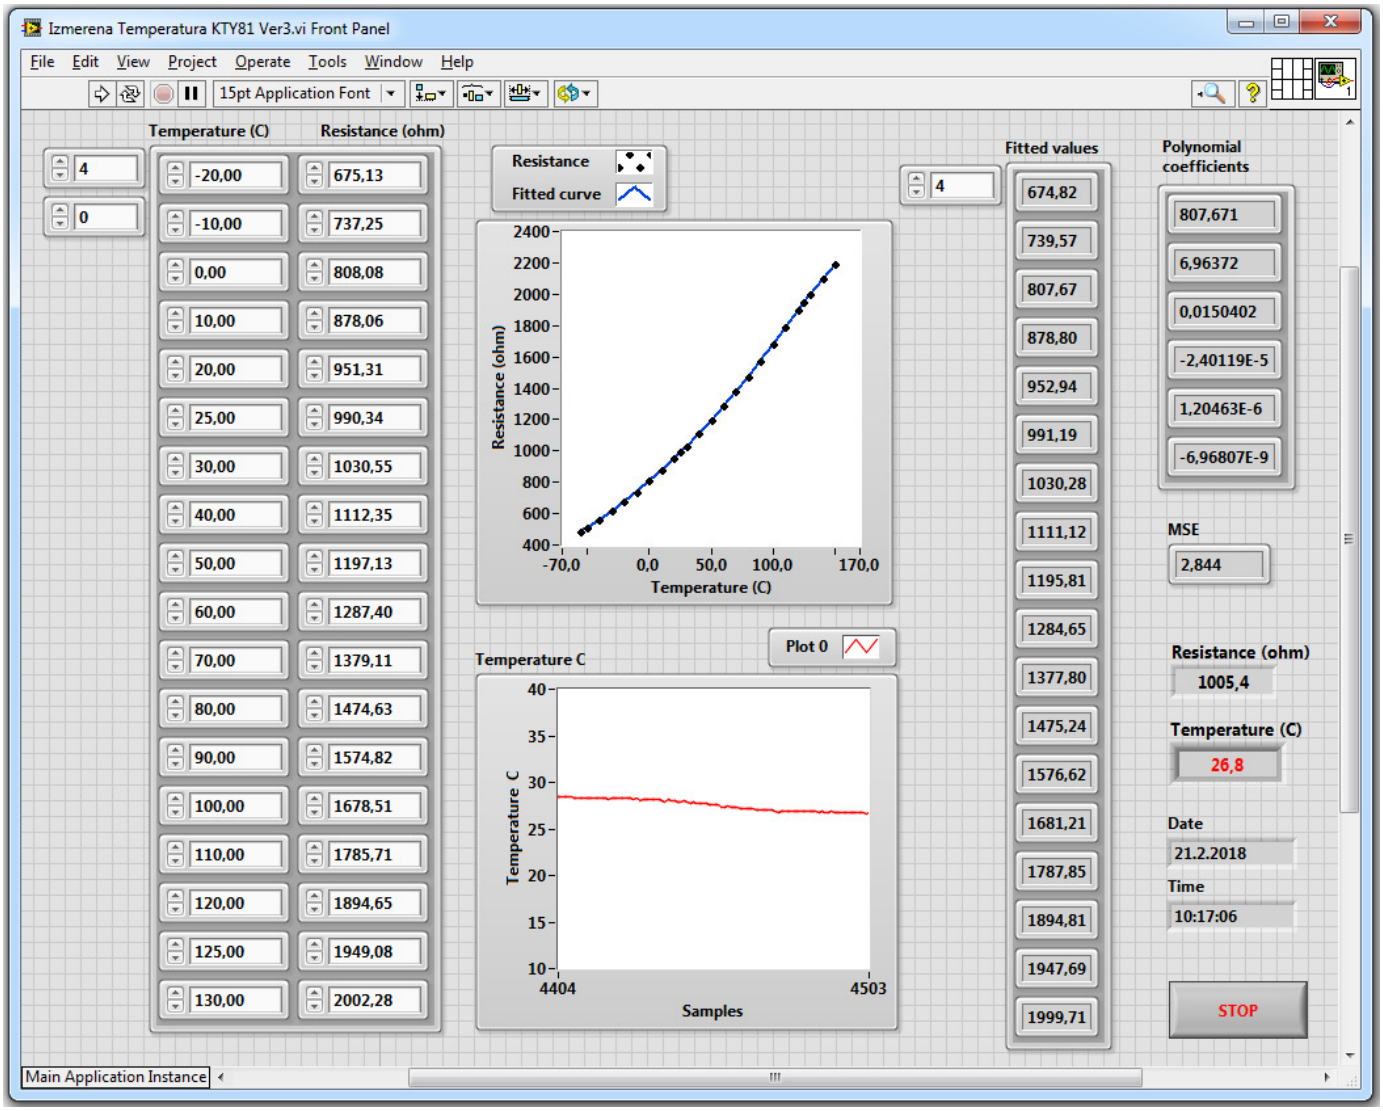

Fig. 3. Front panel of realized measurement program in LabVIEW programing package using LIFA functions

V. Conclusion

This paper presents the practical realization of a measuring device for calibration and temperature measurement using silicon sensors. With minor modifications in the program, the system could also be used to perform temperature measurements with other sensors that possess nonlinear characteristics.

Simulacioni model stohastičkog fleš A/D konvertora

Nikola Petrović, Dragan Pejić, Marjan Urekar, Đorđe Novaković i Nemanja Gazivoda

***Apstrakt*— Na osnovu potreba za ispitivanjem rada kreiranog sistema na Fakultetu tehničkih nauka, Katedra za električna merenja, pristupilo se projektovanju i izradi simulacionog modela postojećeg sistema stohastičkog fleš A/D konvertora. Simulacioni model je kreiran u MATLAB programskom okruženju koja je imala zadatak da simulira rad postojećeg sistema, kao i kombinacije različitih uticaja na njega.**

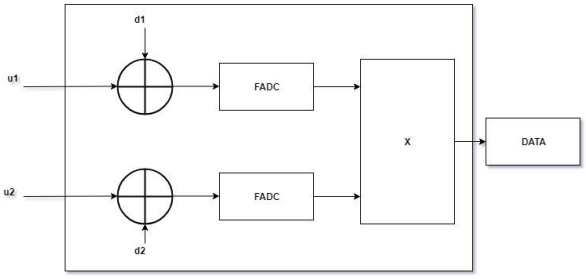
Zbog potrebe za simuliranjem velikog broja podataka, bilo je neophodno izvršiti optimizaciju modela i prilagođavanje dostupnim računarskim konfiguracijama, kao i čuvanje dobijenih podataka, parametara, rezultata i grafika.

***Ključne reči*— SFADC, Matlab, Multithreading, Big Data Analysis**

I. Uvod

Pod digitalnim merenjem danas se podrazumeva digitalno merenje standardnom sempling metodom (SSM). Unapređenje SSM se sastoji u: što tačnijem semplovanju, što je tehnološki problem, što dužoj reči A/D konvertora (ADC), što je, takođe, tehnološki problem i što većoj brzini ADC, što je isto tako tehnološki problem. Postoji metodološka kontradikcija između dužine reči ADC i njegove brzine: brzi ADC imaju kratku digitalnu reč, a ADC duge reči su spori. I ova kontradikcija se danas prevazilazi tehnološki, što je komplikovano, dugotrajno i skupo.

U pokušaju da se prevaziđe navedena metodološka kontradikcija, sredinom devedesetih godina prošlog veka, na Katedri za električna merenja FTN u Novom Sadu, uspešno je razvijena Stohastička Digitalna Merna Metoda (SDMM) [1-3]. SDMM je potpuno različita paradigma digitalnih merenja od SSM, i predstavlja metodološki iskorak u digitalnim merenjima. Naime, u SDMM se, za razliku od SSM, merena veličina ne posmatra i meri samo u tački (vremenskom trenutku), nego u skupu tačaka na intervalu na vremenskoj osi. Dalje, koriste se najbrži, fleš A/D konvertori (FADC) niske rezolucije, najčešće dvobitne. Oni su izuzetno jednostavni, robusni i pouzdani. Jednostavan FADC ima vrlo mali broj izvora sistematske greške koji se lako identifikuju i greška može da se otkloni. Prema tome, SDMM je inherentno vrlo tačna. Dvobitni FADC ima veliku grešku kvantizacije pa, na prvi pogled, izgleda da je veliki problem preciznost. Ovaj problem se efikasno rešava dodavanjem slučajnog uniformnog šuma (ditera), čime nastaje stohastički fleš A/D konvertor (SFADC), pa je SDMM i vrlo precizna. Kratka dvobitna reč SFADC ima za posledicu i vrlo jednostavan blok za osnovnu obradu – množenje i akumulaciju – (multiply and accumulate, MAC).



Sl. 1. Grafički prikaz sistema

Na slici 1. se nalazi šematski prikaz modelovanog sistema, pri čemu su u1 i u2 ulazni naponi, d1 i d2 su generisani diteri koji se dodaju na signale u1 i u2 nakon čega se vrši A/D konverzija tih signala, X predstavlja kolo za množenje dobijenih vrednosti i DATA predstavlja izlaznu brojnu vrednost.

II. Slučajne i sistematske greške

Osnovni problem kod stohastičke metode je prisustvo slučajne greške u velikom iznosu, uzrok ove greške je signal ditera koji se dodaje na ulazni signal. Usrednjavanjem signala se dolazi do zaključka da je uticaj slučajne greške obrnuto srazmeran dužini merenja signala. **Greška opada sa kvadratom dužine trajanja merenja** [4]**.**

Sistematske greške su manje od slučajne i ne zavise od trajanja merenja signala, one zavise od fizičkih osobina komponenti sistema. Sa dovoljnom količinom podataka za usrednjavanje, moguće je potisnuti slučajnu grešku i posmatrati sistematske greške. Potrebna količina podataka zavisi od frekvencije odabiranja, frekvencije signala, kao i matematičkog modela posmatrane komponente sistema.

Tokom simulacije rada celokupnog sistema i analize svih komponenata, za jednu kombinaciju parametara komponenata sistema i jedan referentni napon, vršili smo merenje signala u trajanju od 1600 sekundi.

Nemanja Gazivoda - Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, nemanjagazivoda@uns.ac.rs

III. PROGRAMSKA SIMULACIJA

S obzirom da testiranje razvijenog sistema za jednu kombinaciju parametara sistema zahteva vreme koje nije zanemarljivo, sa kombinatorikom parametara sistema se vreme znatno produžava. Za ispitivanje svih kombinacija parametara bi sistem morao da radi više od dve godine bez prestanka.

Zbog toga je neophodno vršiti simulacije sistema koje daju znatno brže rezultate i mogućnosti simulacije različitih parametara sistema. Slika 1. prikazuje šematski prikaz sistema, pri čemu je izlaz sistema brojna vrednost DATA.

Vrednost napona U_m se izračunava na osnovu formule:

$$U_m = \sqrt{\frac{2 \times DATA}{K \times t}} \quad (1)$$

, gde je DATA suma izlaz akumulatora, K predstavlja koeficijent za određenu rezoluciju A/D konvertora, a t je vreme merenja signala.

A. Ulazni simulacioni podaci

U cilju definisanja ulaznih simulacionih podataka, neophodno je definisati sledeće vrednosti:

- Skup vrednosti rezolucija A/D konvertora
- Skup referentnih napona
- Skup vrednosti trajanja simulacionog merenja
- Broj ponavljanja simuliranog merenja
- Skup binarnih vrednosti primene algoritma svičevanja
- Skup vrednosti napona ofseta A/D konvertora
- Maksimalni napon
- Minimalni napon
- Frekvenciju odabiranja
- Frekvenciju signala
- Skup vrednosti napona ofseta D/A konvertora
- Skup rednih brojeva simuliranih problema D/A konvertora
- Skup vrednosti rezolucija D/A konvertora

Na osnovu unetih podataka se vrši kombinatorika i kreira skup mogućih kombinacija ulaznih parametara. Svakoj kombinaciji se dodeljuje unikatna šifra koja se čuva u tabeli.

B. Generisanje ditera

Jedan od ključnih delova stohastičkog fleš A/D konvertora jeste diter, nasumično generisani signal sa uniformnom raspodelom amplitude jednog praga A/D konvertora. U ovom radu, postoje četiri opcije za generisanje ditera:

1. Idealni slučaj generisanja ditera
2. Generisanje ditera sa multiplikativnim ofsetom. Svaka vrednost ditera se množi sa 1 + ofset.
3. Generisanje ditera sa kumulativnim (aditivnim) ofsetom. Svaka vrednost ditera se sabira sa ofsetom.
4. Generisanje ditera sa konačnim skupom vrednosti, određenim D/A konverzijom i njenom rezolucijom

C. Određivanje koeficijenta K

Koeficijent K je vrednost koja se menja za različit broj bita A/D konvertora i pre testiranja programa je neophodno odrediti za svaki broj bita. Postupak određivanja koeficijenta K je sledeći: Generisanje ulaznih signala sa dovoljnim brojem ponavljanja i različitim referentnim vrednostima napona; Određivanje koeficijenata K za svaki signal na osnovu (2); Čuvanje rezultata u fajlovima pod šifrovanim imenom; Prolazak kroz sačuvane rezultate za isti broj bita i usrednjavanje vrednosti koeficijenta K; Čuvanje koeficijenta K u fajlu K.mat

$$K = \frac{2 \times DATA}{U_m^2 \times t} \quad (2)$$

D. A/D konverzija

A/D konverzija predstavlja pretvaranje ulaznog analognog signala u skup brojnih vrednosti definisanih rezolucijom i naponskim opsegom A/D konvertora.

Konvencionalna metoda simulacije A/D konvertora traži veće računarske resurse i vreme u zavisnosti od rezolucije A/D konvertora. Iz tog razloga je bilo neophodno kreirati vektorizovanu simulaciju koja zahteva jednako vreme za svaku rezoluciju A/D konvertora.

1) Ofseti A/D konvertora

Ofseti A/D konvertora se definišu posebno za svaki prag i za svaki vremenski trenutak. Prethodno definisani ofseti se dodaju na ulazni signal za svaki odgovarajući prag A/D konvertora.

2) Postupak svičevanja

U cilju potiskivanja uticaja ofseta A/D konvertora, koristi se postupak svičevanja, što fizički podrazumeva zamenu ulaza A/D konvertora sa periodom koja je dva puta veća od periode ulaznog signala [5-6]. Ova ideja suzbijanja ofseta periodičnim unakrsnim preklapanjem (PUP) ulaza je poznata i široko primenjena tehnika u preciznim operacionim pojačavačima, gde se koristi za poništavanje dinamičkog ofseta.

Postupak svičevanja u simulaciji podrazumeva promenu znaka vrednosti ofseta sa periodom koja je dva puta veća od periode ulaznog signala.

IV. OPTIMIZACIJA SIMULACIJE

Mogućnosti simulacije zavise od računarske konfiguracije, kao i strukture simulacije. U cilju optimalnog iskorišćenja računarskih resursa, neophodno je izvršiti optimizaciju spram dostupnim resursima [7-8].

A. Vektorizacija

MATLAB programski jezik smešta promenljive u radnu

memoriju računara, što znači da je potrebno kreirati promenljive koje svojim sadržajem menjaju prolazak kroz petlje. Na taj način se skupovi podataka obrađuju kao celina, a ne pojedinačno. Ovaj postupak značajno ubrzava simulaciju, ali zahteva veću radnu memoriju računara kod većih količina podataka.

Prvi korak vektorizacije uzima kao promenljivu jedan jednodimenzionalni vektor signala.

Drugi korak vektorizacije uzima kao promenljivu dvodimenzionalni vektor koji u sebi sadrži jednodimenzionalne vektore signala za sva ponavljanja.

B. Planiranje

U slučaju da postoji više računara koji obrađuju podatke, neophodno je uraditi planiranje, što podrazumeva raspodelu mogućih kombinacija na sve računare spram njihovih kapaciteta i mogućnosti. Celokupan postupak se izvodi unošenjem raspoloživih računara i odnosa njihovih kapaciteta, kao i potrebnih kombinacija koje se dele.

C. Paralelno programiranje

MATLAB omogućava višejezgarnu optimizaciju petlji pomoću funkcije parfor koja paralelno pokreće onoliko paralelnih procesa koliko mikroprocesor ima jezgara. Tokom rada parfor funkcije potrebni resursi radne memorije se multipliciraju. U okviru programskog okruženja je moguće ručno precizirati koliko jezgara za koliko procesa se koristi.

D. Operacije nad velikim podacima

Ukoliko se obrađuju podaci koji zahtevaju veće resurse radne memorije nego što su dostupni, neophodno je pristupiti dodacima za obradu velikih podataka, što podrazumeva smeštanje podataka iz radne memorije na hard disk.

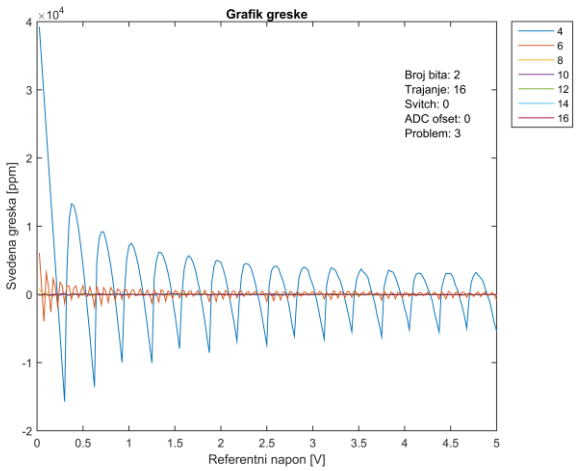
Prva mogućnost je upotreba MATLAB programskih dodataka za obradu podataka, pri čemu je tada potrebno izvršiti minorne izmene programa i odrediti lokaciju smeštenih fajlova.

Druga mogućnost je podešavanje veličine Windows Page File datoteke koja predstavlja prostor za virtuelnu radnu memoriju računara. Ova datoteka je ograničena veličinom i brzinom hard diska i preporučuje se upotreba SSD hard diska. Uz primenu ove mogućnosti nije potrebno vršiti izmenu programa.

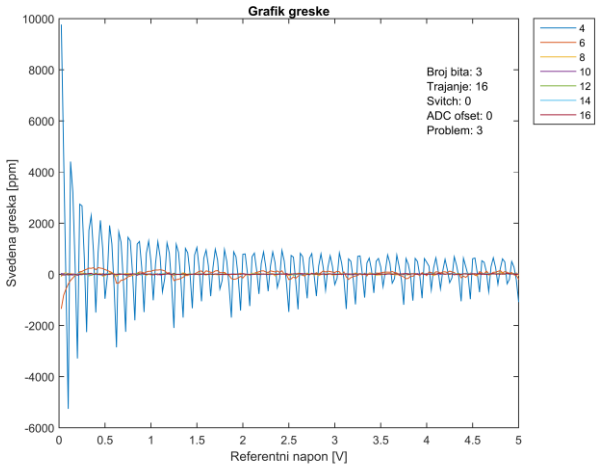
Upotreba operacija nad velikim podacima usporava simulacije za 50%, ali pruža mogućnost pokretanja simulacija na računarskim konfiguracijama koje nemaju dovoljnu količinu RAM memorije.

V. REZULTATI

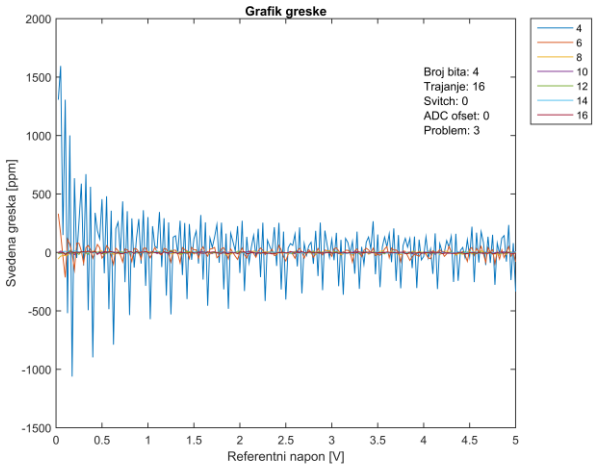
Nakon izvršenih simulacija sistema za različite uslove, svi dobijeni rezultati se čuvaju i arhiviraju u odgovarajućim datotekama. Dobijene rezultate je moguće interpretirati i porediti na različite načine u zavisnosti od potreba korisnika. Nakon postavljanja željenih poređenja, algoritmi za grafički prikaz generišu grafike dobijeni rezultata.



Sl. 2. Grafički prikaz rezultata simulacije sistema sa dvobitnim A/D konvertorom



Sl. 3. Grafički prikaz rezultata simulacije sistema sa trobitnim A/D konvertorom



Sl. 4. Grafički prikaz rezultata simulacije sistema sa četvorobitnim A/D konvertorom

Na slikama 2, 3 i 4 su prikazani rezultati za simulaciju sa rezolucijom A/D konvertora od 2, 3 i 4 bita. Na svakom

grafiku su prikazani rezultati za simulaciju sistema sa 4, 6, 8, 10, 12, 14 i 16 bita rezolucije D/A konvertora. Na ovim slikama je prikazan uticaj konačne rezolucije DACa koji generiše diter. Što je veća rezollucija ditera manji je njegov doprinos grešci i vidimo više preseka sa horizontalnom osom.

VI. ZAKLJUČAK

Trenutni sistem za simulaciju se pokazao kao uspešan uz rezultate koji su približni dobijenim rezultatima sa stvarnim sistemom. Sa trenutnim mogućnostima, sistem se prilagođava računarskim konfiguracijama na kojima se pokreće i pruža mogućnost ručno planiranog distribuiranog računanja.

Plan za dalji razvoj projekta je dodatna vektorizacija generisanih podataka, što podrazumeva kreiranje multidimenzionalne matrice podataka i njenu automatizovanu višejezgarnu obradu.

Osim toga, ideja je razvoj serverske obrade podataka uz kreiranje sopstvenih servera koji bi pružili mogućnost znatno bržeg rada celokupnog sistema.

Kao nastavak, pruža se mogućnost i kreiranja sistema mašinskog učenja, koji bi znatno olakšao generisanje podataka, određivanje koeficijenata i opisivanje sistematskih grešaka.

Kreirani sistem će se u budućnosti koristiti kao alat za ispitivanje međusobnog uticaja više problema istovremeno, što pruža mogućnost boljeg shvatanja međusobnog dejstva velikog skupa sistematskih uzročnika, što bi dalje trebalo da usmeri na načine potiskivanja njihovog uticaja, kao i višedimenzionalnu optimizaciju parametara sistema u cilju dobijanja optimalnog rešenja.

ABSTRACT

Based on the needs for testing the performance of the created system at the Faculty of Technical Sciences, Department of Electrical Measurements, we designed and developed a simulation model of the existing system of stochastic flash A / D converter. A simulation was performed using the MATLAB programming language, which had the task of simulating the operation of the existing system, as well as a combination of various effects on it.

Due to the need to simulate a large number of data, it was necessary to perform model optimization and adjustment to the available computer configurations, as well as to store the obtained data, parameters, results and graphics.

Simulation model of a stochastic flash A / D converter

SISTEM ZA DETEKCIJU POŽARA ZASNOVAN NA MIKROPROCESORSKIM MERNIM MODULIMA

Milan Šaš i Đorđe Novaković, *Member, IEEE*

***Apstrakt*—Ovaj rad prikazuje sistem za detekciju požara, zasnovan na mikroprocesorskom razvojnom sistemu EasyPIC Pro v7, sa mikrokontrolerom PIC18F87K22. Kao senzore za detekciju odabranih parametara koriste se SMOKE click (MIKROE-2560) baziran na MAX30105 senzoru za detektovanje dima, FLAME click (MIKROE-1820) baziran na PT334-6B senzoru za detektovanje plamena i CO click (MIKROE-1626) koji koristi MQ-7 senzor za merenje koncetracije ugljen-monoksida.**

***Ključne reči*— Mikroprocesorski merno-akvizicioni sistemi; Protivpožarni sistem; Dojava požara; Merenje; Senzori.**

I. UVOD

Sistem za detekciju i dojavu požara je sastavni deo svakog objetka, odnosno zgrada, kuća, stanova, hala i drugih objekata sličnih namena. Osnovni zadatak sistema je detekcija i dojava požara u ili na nekom objektu. U svetu već postoje rešenja za ovaj sistem koji se baziraju, između ostalog, na Neuronskim mrežama [1] i koriste se razni algoritmi koji služe za jasniju i precizniju detekciju požara, kako ne bi došlo do lažne uzbune [2][3].

Ovaj sistem je razvijen u sklopu predmeta mikroprocesorski merno-akvizicioni sistemi [4] na EasyPIC Pro V7 [5] razvojnom okruženju koje je razvija kompanija Mikroelektronika [6] i u čijem središtu se nalazi mikrokontrolerom PIC18F87K22 [7]. Kako svaki sistem slične namene ima određene senzore tako i ovaj sistem ima svoje senzore za detekciju požara. Odabrani senzori su senzori za dim, plamen i ugljen-monoksid koji se nalaze na zasebnim click pločicama koje je takođe razvila Mikroelektronika. Same pločice se povezuju na razvojno okruženje preko microBUS terminala. Komunikacija sa senzorima se vrši preko I2C (Inter-Intergrated Circuit) protokola ili preko interapta koji se šalje preko određenog pina na samoj pločici. U nastavku će biti razmotrene i detaljno objašnjene komponente koje su korišćenje kao senzori.

Milan Šaš – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: milan.sas.97@gmail.com)

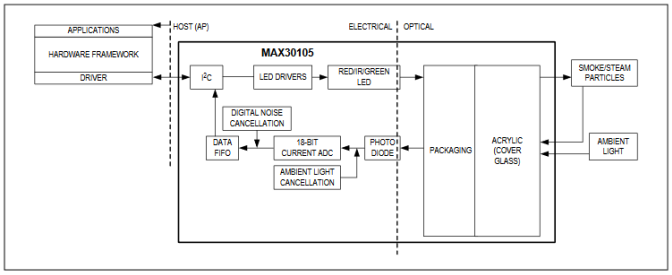
Đorđe Novaković - Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: djordjenovakovic@uns.ac.rs).

II. SMOKE CLICK

Smoke click u sebi sadrži MAX30105 [8] visoko-osetljivi optički senzor za detekciju dima. Pločica je dizajnirana tako da može da se napaja sa 3.3V ili 5V. Komunikacija sa mikrokontrolerom se vrši preko I2C interfejsa sa dodatnom funkcijom koju omogućava INT pin. Na slici 1 se vidi sam izgled pločice:

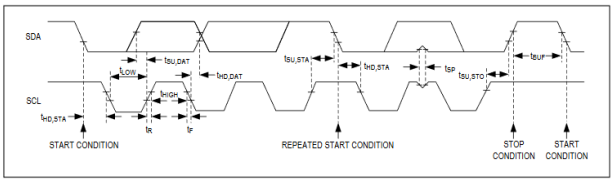
Sl. 1. Smoke click – izgled [9]

MAX30105 je čip kompanije Maxim Integrated sa integrisanim modulom za detektovanje čestica. Sadrži interni LED, foto detektore, optičke elemente i ″low noise″ elektroniku. Koristi se za detekciju dima i najveća primena je u protivpožarnim sistemima. Pošto je malih dimenzija može da se koristi i u mobilnim sistemima. Čip se napaja sa 1.8V i odvojeno sa 5V koji se koristi za napajanje LED-a. Potrošnja struje iznosi 0.7 μA. Sistemski dijagram je dat na slici 2:



Sl. 2. MAX30105 sistemski dijagram [8]

Pošto se komunikacija sa mikrokontrolerom vrši preko I2C komunikacije na sledećoj slici je dat dijagram po kome se vrši komunikacija:



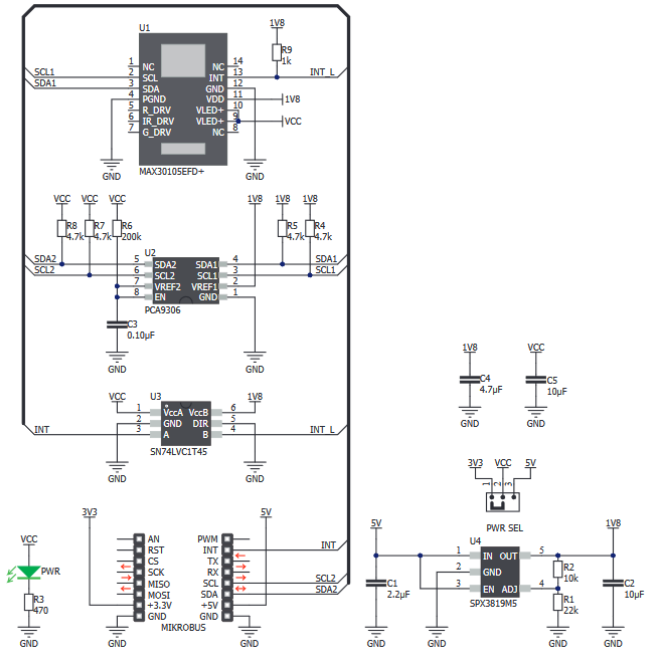
Sl. 3. I2C Komunikacija [8]

Na SL. 4 je dat Pinout dijagram pločice:

Notes	Pin	mikro BUS				Pin	Notes
	NC	1	AN	PWM	16	NC	
	NC	2	RST	INT	15	**INT**	Active-Low Interrupt (Open-Drain).
	NC	3	CS	TX	14	NC	
	NC	4	SCK	RX	13	NC	
	NC	5	MISO	SCL	12	**SCL2**	I2C Clock Input
	NC	6	MOSI	SDA	11	**SDA2**	2C Clock Data, Bidirectional (Open-Drain)
Power supply	**+3.3V**	7	3.3V	5V	10	**+5V**	Power supply
Ground	**GND**	8	GND	GND	9	**GND**	Ground

Sl. 4. Pinout dijagram smoke pločice [9]

Pored samog senzora na samoj pločici se nalaze još i PCA9306 čip [10] koji se koristi za I2C komunikaciju, SN74LVC1T45 čip [11] koji je jednobitni neinvertujući bus transrisiver i SPX3819M5 čip [12] koji je regulator pozitivnog napona. Na SL. 5. Se nalazi šema same pločice:



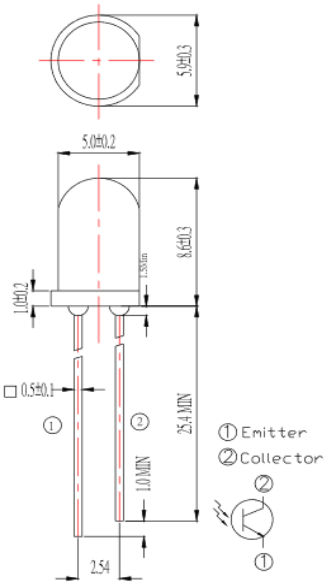
Sl. 5. Šema Smoke pločice [9]

III. FLAME CLICK

Flame click je uređaj koji na sebi ima PT334-6B [13] silikonski foto tranzistor koji je prekriven crnim epoksijem i zbog toga reaguje samo na infracrvenu svetlost. Koristi se kao alarm u slučaju vatre tako što se podešava ″threshold″ na potenciometru na samoj pločici. Kada vrednost pređe tu granicu šalje se interapt preko INT pina. Senzor takođe može da šalje i kontinualni analogni signal preko AN pina. Pločica može da se napaja sa 3.3V i 5V. Na Sl. 6. je dat prikaz pločice:

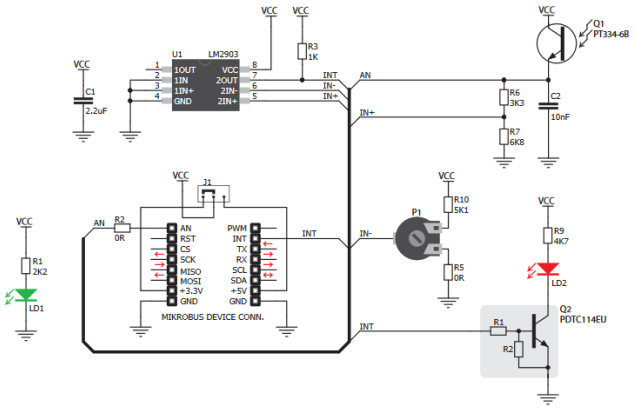
Sl. 6. Flame click – Izgled [14]

PT334-6B je veoma brz i veoma osetljiv NPN silikonski foto tranzistor koji se nalazi u standardnom 5 mm pakovanju. Pošto je prekriven crnim epoksijem, uređaj je osetljiv na infracrvenu svetlost. Brzo reaguje i veoma je osetljiv na svetlost pa se može primenjivati u infrared sistemima, kamerama, protivpožarnim alarmima kao i za hvatanje bubašvaba. Na Sl. 7. je dat izgled foto tranzistora:



Sl. 7. PT334-6B – Izgled [13]

Na pločici, osim PT334-6B, se nalazi i LM2903 [15] čip koji se koristi kao komparator za detektovanje praga provođenja. Na Sl. 8. je dat Pinout dijagram i šema Flame pločice:



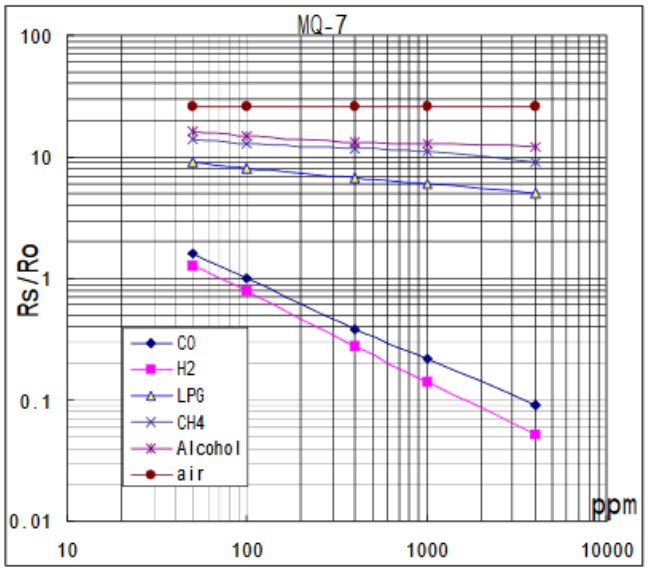
Sl. 8. Pinout dijagram i šema Flame pločice [16]

IV. CO CLICK

Ova pločica se koristi za merenje ugljen-monoksida u okolini i to postiže sa MQ-7 [17] gasnim senzorom. Na samoj pločici se nalazi potenciometar kojim se zadaje ″threshold″. Pločica se napaja sa 5V. Komunikacija sa mikrokontrolerom se vrši preko AN pina. Izgled pločice je dat na Sl. 9:

Sl. 9. CO click – izgled [18]

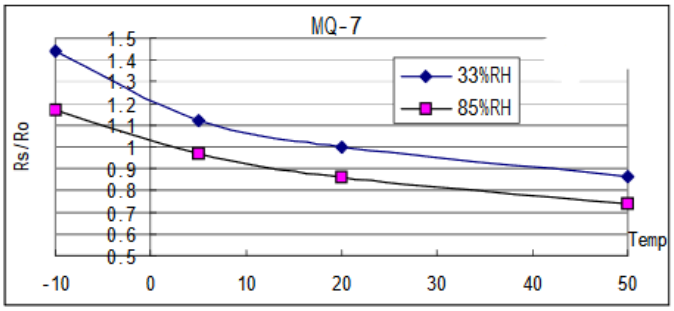
MQ-7 je gasni senzor koji služi za detekciju ugljen-monoksida (CO). Deo koji detektuje gas je napravljen od kalaj-dioksida (SnO2) koji ima manju provodnosti od vazduha. Kada se pojavi gas menja se i provodnosti. Opseg detektovanja CO je između 20ppm – 2000ppm. Kalibracija se vrši putem potenciometra koji se nalazi na pločici. Potrebno je da, kada se vrši kalibracija, senzor bude na radnoj temperaturi. Preporuka je da se upali oko 48h pre kalibracije. Na Gr. 1. je dat grafik osetljivosti senzora pri temperaturi od 20ºC, .vlažnosti vazduha od 65%, O2 koncentraciji od 21%:



Gr. 1. Karakteristika MQ-7 senzora [17]

Rs – otpornosti senzora na 100ppm CO u čistom vazduhu
Ro – otpotnost senzora na različitim koncentracijama CO

Očitavanje senzora takođe zavisi od temperature i vlažnosti vazduha. Na Gr. 2 je data zavisnost otpornosti od ovih parametara:



Gr. 2. Zavisnost otpora od temperature i vlažnosti vazduha [17]

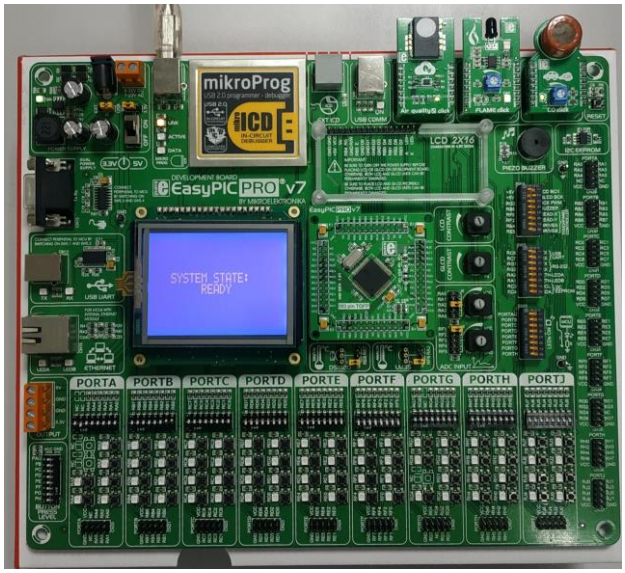
Na SL. 10 je dat Pinout dijagram pločice:

Notes	Pin	mikroBUS™				Pin	Notes
Analog output	AN	1	AN	PWM	16	NC	Not connected
Not connected	NC	2	RST	INT	15	NC	Not connected
Not connected	NC	3	CS	TX	14	NC	Not connected
Not connected	NC	4	SCK	RX	13	NC	Not connected
Not connected	NC	5	MISO	SCL	12	NC	Not connected
Not connected	NC	6	MOSI	SDA	11	NC	Not connected
Not connected	NC	7	3.3V	5V	10	+5V	Power supply
Ground	GND	8	GND	GND	9	GND	Ground

Sl. 10. Pinout dijagram CO pločice [18]

V. ZAKLJUČAK

Ovakav sistem za detekciju požara može biti veoma koristan u navedenim primenama zato što se ne oslanja na stanje odnosno prisutnost samo jedne komponente koja dovodi do aktiviranja alarma već se vrši merenje i obradu tri različite veličine koje zajedno mogu da dovedu do katastrofalnih posledica pre svega po čoveka pa i po objekte. Sistem može da se konfiguriše tako da radi kao ″Standalone″ uređaj koji bi se napajao iz baterijskog napajanja. Na slici 10. je dat izgled sistema:



Sl. 10. Izgled sistema

ZAHVALNICA

Želeo bih da zahvalim profesoru Platonu Sovilju na velikoj pomoći i podršci pri izradi ovog rada. Takođe, veliko hvala celoj Katedri za električna merena na Fakultetu tehničkih nauka u Novom Sadu. Na kraju bih se zahvalio i kompaniji Mikroelektronika na tehničkoj podršci ovom projektu.

ABSTRACT

This paper presents the system that works as a fire detection system, based on development system EasyPIC Pro V7, with a PIC18F87K22 microcontroller. As sensors for detection of certain parameters system uses SMOKE click (MIKROE-2560) based on MAX30105 sensor for detection of smoke, FLAME click (MIKROE-1820) based on PT334-6B sensor for detection of flame and CO click (MIKROE-1626) based on MQ-7 carbon-monoxide concentration sensor.

System for fire detection based on microprocessor measuring modules

Milan Šaš, Đorđe Novaković

SMART Home sistem zasnovan na mikroprocesorskim mernim modulima

Duško Gajinović, Đorđe Novaković, IEEE member

***Apstrakt*—Ovaj rad prikazuje sistem, koji vrši očitavanje nekoliko senzorskih modula koristeći microBUS koji je baziran na I2C protokolu, kao i očitavanje vrednosti sa analognih senzora. Sistem je realizovan na EasyPIC Pro V7 ploči sa PIC18F87K22 mikrokontrolerom. Senzorski moduli u ovom sistemu su Weather Click koji je baziran na senzoru BME-280 za očitavanje temperature, atmosferskog pritiska i vlažnosti vazduha, kao i Proximity Click koji koristi VCNL4010 za detektovanje korisnika ispred glavne konzole. Takođe se koriste i analogni senzori LM35 za merenje temperature u pojedinačnim prostorijama. Zatim mikrokontroler vrši obradu svih očitanih signala, i prikazuje ih na 128x64 GLCD ekranu sa TouchPanel-om. Osim prikazivanja očitanih podataka, GLCD služi i za upravljanje rasvetom u pojedinačnim prostorijama kuće, kao i otključavanje i zaključavanje ulaznih vrata.**

***Ključne reči*— Mikroprocesorski merno-akvizicioni sistemi; Senzori; GLCD; Touchscreen; I2C; Temperatura; Vlažnost vazduha; Atmosferski pritisak; Kontrola električnih uređaja.**

I. Uvod

Ovaj rad je nastao na osnovu ideje da se konstruiše sistem koji bi omogućio korisniku da ima uvid u sve parametre koje očitava set odabranih senzora i mogućnost bezbednosne kontrole u vidu alarmnog sistema i elektronskih brava.

Ceo sistem je zasnovan na EasyPIC Pro V7 [1] razvojnoj ploči, na kojoj se nalazi PIC18F87K22 [2] mikrokontroler. Ova razvojna ploča i svi senzorski moduli su razvijeni i proizvedeni od strane kompanije Mikroelektronika [3]. Konkretno su u ovom projektu implementirani moduli Weather Click (MIKROE-1978) [4] za merenje temperature, atmosferskog pritiska i vlažnosti vazduha, kao i Proximity Click (MIKROE-1445) [5] za merenje udaljenosti korisnika od glavne upravljačke konzole. Osim tih modula koriste se i analogni senzori LM35 za merenje temperature. Njihove izlazne vrednosti se mere pomoću A/D konvertora koji je integrisan u sam PIC mikrokontroler. Sve prikupljene informacije se obrađuju i prikazuju na 128x64 GLCD ekranu koji se nalazi na samoj razvojnoj ploči. Interfejs je napravljen tako da prikazuje samo osnovne informacije dok je sistem u "standby" modu, a svi ostali detalji su dostupni u podmeniju, koje korisnik sam bira pritiskom na ekran.

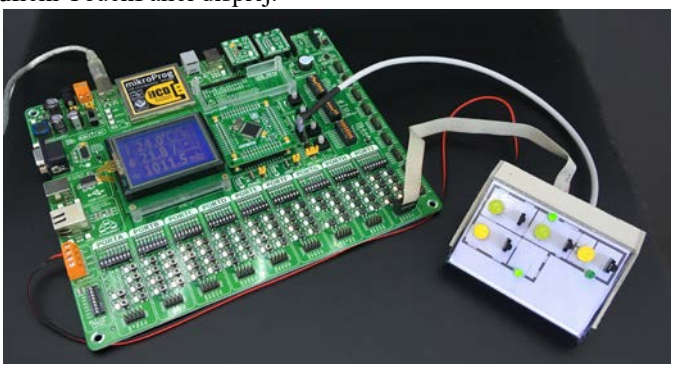
Ovaj sistem je razvijen u sklopu predmeta Mikroprocesorski merno-akvizicioni sistemi [6].

Duško Gajinović – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: gajinovic.dusko@gmail.com)

Đorđe Novaković - Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: djordjenovakovic@uns.ac.rs)

II. Interfejs

Početna ideja je bila da se napravi grafički intefejs pomoću kojeg se jednostavno prate očitani parametri, kao i upravljanje rasvetom i električnim bravama. U tu svrhu sam koristio grafički TouchPanel displej.



Sl. 1. SMART Home sistem

Početni ekran prikazuje osnovne informacije kao što su temperatura, vlažnost vazduha i pritisak dok se sistem nalazi u standby modu.

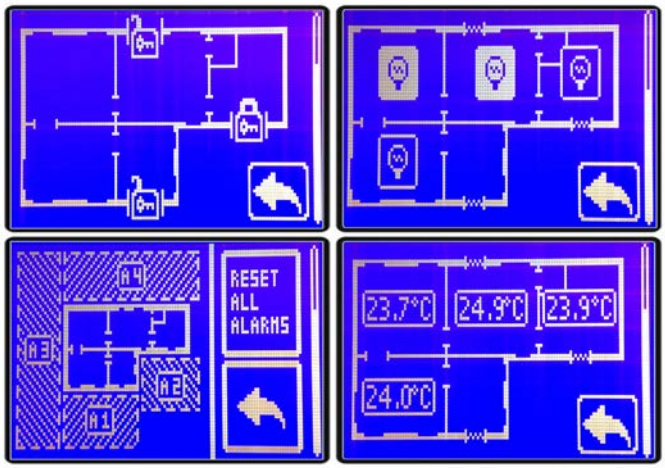
Sl. 2. "Standby" ekran

Glavni meni je dostupan pritiskom na bilo koji deo ekrana.

Sl. 3. Glavni meni

Na glavnom meniju je moguć izbor jednog od pet različitih podmenija:

1. “House Locks” meni služi za otključavanje i zaključavanje svih elektronskih barava na ulaznim vratima objekta.
2. “House Lights” meni omogućava kontrolu glavne rasvete u svakoj prostoriji.
3. “House Alarms” meni daje informaciju o aktivaciji alarmnog sistema oko objekta. Prostor oko objekta se može podeliti na više zona koje se simultano prate. Aktivacija bilo koje zone je prikazana i na “standby” meniju.
4. “House Temps” dozvoljava uvid u trenutnu temperaturu svake prostorije.
5. “System Info” daje sve neophodne informacije u vezi sistema, kao i proveru ispravnosti svih modula u sistemu.

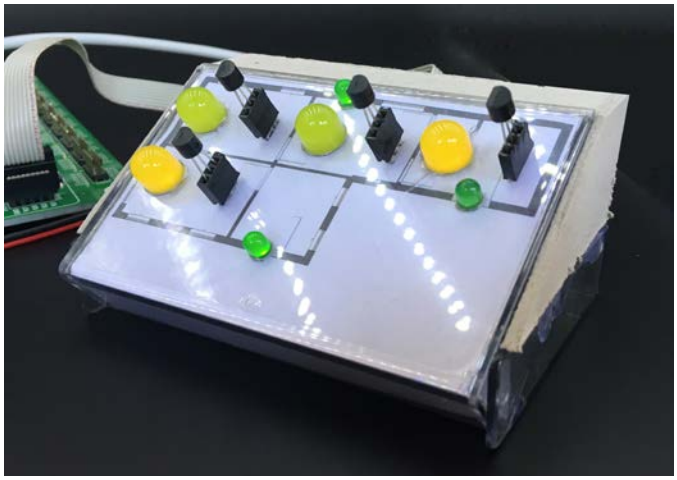


Sl. 4. Podmeniji (House Locks, House Lights, House Alarms, House Temps)

Sa desne strane svakog menija se nalazi grafički prikaz tajmera koji odborojava 30 sekundi od poslednjeg unosa ili promene. Ako korisnik duže stoji ispred glavne konzole, sensor udaljenosti će to detektovati, i tajmer neće biti aktivan.

Ovaj sistem se može jednostavno primeniti u različitim objektima, bez obzira na broj i raspored prostorija, kao i izgled i veličinu spoljnog okruženja. Primena je veoma široka, može se implementirati u sve vrste objekata (stambeni, poslovni, industrijski), u zavisnosti od potreba. Sistem se može nadograditi širokom paletom senzora i modula, koji omogućavaju preciznije i detaljnije praćenje svih željenih parametara.

Uz glavnu ploču ide i maketa objekta, koja u ovom slučaju ima četiri prostorije, u svakoj sensor za temperaturu, kao i indikator stanja rasvete i električnih brava. Maketa se može videti na slici broj 5:



Sl. 5. Maketa objekta

III. Senzorski Moduli

SMART Home sistem vrši očitavanja pomoću dva senzorska modula, Weather Click [4] i Proximity Click [5].

Weather Click (MIKROE-1978) je senzor atmosferskih veličina, koji je baziran na senzoru Bosch BME280 [7]. Ovaj senzor vrši merenja temperature, vlažnosti vazduha i atmosferskog pritiska, i dizajniran je za malu potrošnju struje i dugoročnu stabilnost. Komunikacija sa mikrokontrolerom se vrši preko I2C interfejsa.

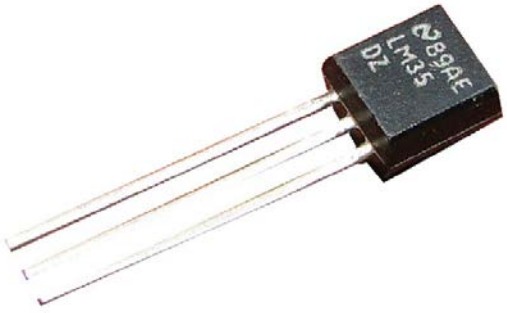
Sl. 6. Weather Click - [4]

BME280 ima visoku tačnost i pouzdanost za sva tri senzora. Senzor vlažnosti vazduha ima vreme odziva od jedne sekunde i preciznost od ± 3% RH. Senzor atmosferskog pritiska ima grešku od 0.25%. Senzori vlažnosti vazduha i pritiska mogu raditi nezavisno jedan od drugog. Najbitnija karakteristka senzora temperature je da ima visoku rezoluciju, u određenom modu, do 20 bita.

Proximity Click (MIKROE-1445) je modul koji je zasnovan na senzoru Vishay Semiconductors VCNL4010 [8], kombinuje infracrvenu LED diodu i PIN fotodiodu za merenje udaljenosti do 20 cm. Takođe može da se koristi kao senzor ambijentalnog svetla.

Sl. 7. Proximity Click – [5]

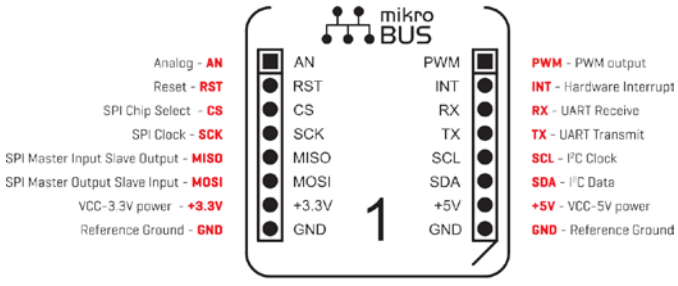
Osim senzorskih modula se koriste i analogni senzori temperature Texas Instruments LM35-DZ [9]. On se koristi za merenje pojedinačnih prostorija objekta, zbog svojih malih dimenzija i male greške merenja, od 0.5°C. Izlazni napon ovog senzora se menja za +10.0 mV/°C u odnosu na 0°C. Taj signal se pretvara u digitalni broj pomoću A/D konvertora, čija je rezolucija 12 bita, koji je integrisan u PIC mikrokontroler.



Sl. 8. Senzor LM35DZ [10]

IV. Struktura platforme

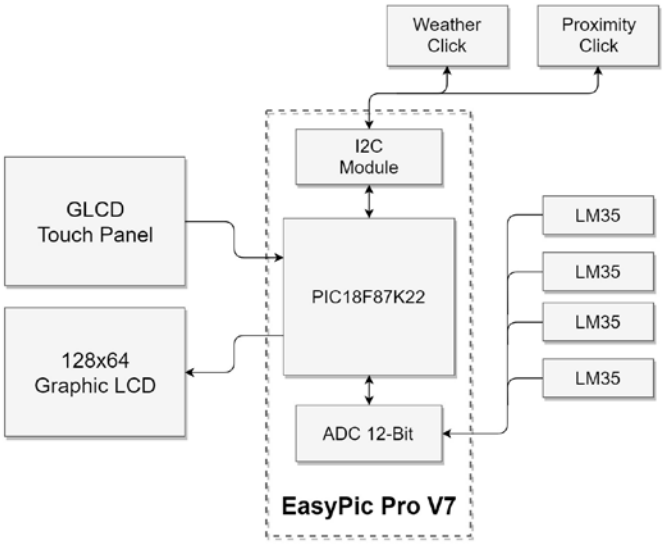
EasyPic Pro V7 je razvojni sistem koji povezuje sve periferne jedinice sa mikrokontrolerom PIC18F87K22. U samom mikrokontroleru se nalazi modul za I2C protokol, koji omogućuje komunikaciju sa senzorskim modulima preko MikroBUS-a, slika 9.



Sl. 9. MikroBUS socket – [11]

Konkretno u ovom slučaju Click pločice komuniciraju sa mikrokontrolerom isključivo preko I2C protokola. MikroBUS je pogodan i za ostale vrste senzora, posto podržava i SPI i UART protokole. Osim toga ima i pinove za PWM, analogni ulaz, kao i pristup jednom interrupt pinu po klik pločici.

Strukturu platforme je najlakše prikazati blok šemom koja je se nalazi na slici 10. Smer strelica prikazuje kako se odvija razmena podataka.



Sl. 10. Blok šema SMART Home sistema

Prilikom aktivacije sistema se inicijalizuju sve periferne jedinice. Prvo se vrši podešavanje PORT-ova mikrokontrolera, kao ulazni ili izlazni, digitalni ili analogni, podešavanje tajmerskih registara, i svih potrebnih protokola.

Nakon toga se inicijalizuje GLCD ekran kako bi sve potrebne informacije, kao i greške, mogle da se prikažu korisniku. Nakon toga se uspostavlja komunikacija sa senzorskim modulima, i na određene adrese se unose bitovi za konfigurisanje samih senzora, kao što su osetljivost, vreme odabiranja i kalibracija. Ubrzo posle toga se isti ti registri za konfigurisanje očitavaju i porede sa već zadatim vrednostima, kako bi se proverilo da li je senzor u potpunosti podešen, u slučaju da nije, ispisuje se greška na ekranu. Takođe se može pristupiti statusu svih perifernih jedinica u “System Info” meniju. LM35 senzori temperature su povezani na PORT-A mikrokontrolera, i sam port je u inicijalizaciji podešen kao analogni ulaz.

Tajmerski interapt je podešen tako da se na svakih 50ms vrši provera da li je bilo novih unosa preko touch panela. U slučaju da jeste, vrši se provera položaja unosa i da li se taj položaj poklapa sa “ikonicom” u datom meniju. Ukoliko se poklapa, poziva se odabrana funkcija. Ubrzo posle toga se radi osvežavanje ekrana, sa novim informacijama ili sa novim podmenijem. Takođe se i posle svakog unosa resetuje tajmer od 30 sekundi i kreće novo odbrojavanje. Ekran se nezavisno

od aktivnosti osvežava svake sekunde, a tome prethodi ponovno očitavanje svih vrednosti koje treba da se prikažu. Po isteku 30 sekundi od poslednjeg unosa, sistem prelazi na standby režim.

V. Zaključak

Sistem SMART Home je realizovan od komponenata koje su dostupne na domaćem tržištu, pristupačnih cena i izuzetnog kvaliteta. Veoma lako se može prilagoditi specifičnim zahtevima tržišta i sama implementacija i upotreba je jednostavna. Moguće je uz male izmene povezati ovaj uređaj sa mobilnim telefonima ili nekim web serverom, za detaljnije praćenje statusa sistema. Sistem je veoma fleksibilan zbog velikog broja senzorskih modula koji se mogu naknadno ugraditi, ukoliko se za to pokaže potreba.

Zahvalnica

Zahvaljujem se profesoru Platonu Sovilju na podršci i pomoći prilikom izrade ovog rada, kao i svim kolegama sa Katedre za električna merenja, na Fakultetu tehničkih nauka u Novom Sadu.

Abstract

This project presents a system that reads multiple sensor modules using microBUS socket which is based on an I2C protocol, as well as reading values from analog sensors. This system was implemented on the EasyPIC Pro V7 board with the PIC18F87K22 microcontroller. Sensor modules for this system are Weather Click, based on the BME-280 sensor for temperature, atmospheric pressure and humidity, as well as the Proximity Click that uses the VCNL4010 sensor to detect users in front of the main console. This system also features analog LM35 sensors that are used to measure temperature in individual rooms. The microcontroller takes the readings from all of the sensors, processes them, and displays them on a 128x64 GLCD with a TouchPanel. Besides displaying the read data, GLCD also serves to manage the lighting in individual rooms of the house, as well as unlocking and locking the front door.

SMART Home system based on microprocessor measuring modules

IMPLEMENTACIJA PID REGULATORA POMOĆU MIKROPROCESORSKIH MERNO-REGULACIONIH MODULA

Žarko Dubajić, Đorđe Novaković, IEEE member

***Apstrakt*— Ovaj rad prikazuje implementaciju PID regulatora u mikroelektronici, koristeći razvojni sistem EasyPIC Pro v7, sa mikrokontrolerom PIC18F87K22. Vrši se regulacija brzine obrtanja elektromotora. Kao senzor za detekciju okretanja osovine elektromotora koristi se inkrementalni enkoder. Za generisanje PWM signala za upravljanje koristi se DC MOTOR 4 click.**

***Ključne reči* — Mikroprocesorski merno-akvizicioni sistemi; PID; Regulacija; Merenje; Senzori; Brzina; Elektromotor.**

I. UVOD

Kontroler je deo sistema automatskog upravljanja koji obavlja upravljačku funkciju. Njegov zadatak je da, generišući upravljački signal , vodi merljivu izlanu veličinu ka referentnoj vrednosti koja je zadata signalom.

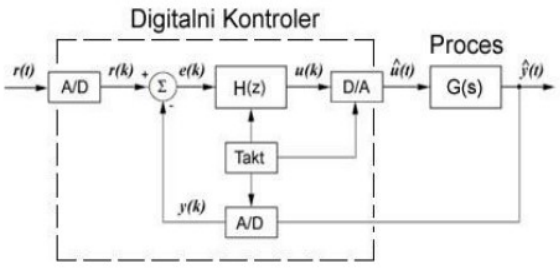
Ovaj sistem je razvijen u sklopu predmeta Mikroprocesorski merno-akvizicioni sistemi [3] na EasyPIC Pro V7 [4] razvojnom okruženju koje razvija kompanija Mikroelektronika [2] i u čijem središtu se nalazi mikrokontrolerom PIC18F87K22 [1].

II. DIGITALNI KONTROLER

Poslednjih decenija digitalna tehnika doživela je revoluciju. U sistemima automatskog upravljanja primat nad analognim preuzeli su digitalni kontroleri. Osnovni razlog je njihova dostupnost odnosno niska nabavna cena , jednostavna primena i održavanje. Digitalni kontoleri u sistemu automatskog upravljanja obavljaju istu funkciju kao i analogni a osnovna razlika između ova dva rešenja je u principu rada. Analogni konroleri izvršavaju svoj upravljački algoritam obradom vremenski neprekidnih signala. Digitalni konroleri obavljaju istu funkciju obradom digitalnih odnosno signala disrketizovanih po vremenu i po nivou. Njihova realizacija osvaruje se primenom digitalnih komponenti što ih čini neuporedivo pristupačnijim nego što su to analogni kontroleri.

Žarko Dubajić – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: zardubajic@gmail.com)

Đorđe Novaković - Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: djordjenovakovic@uns.ac.rs)

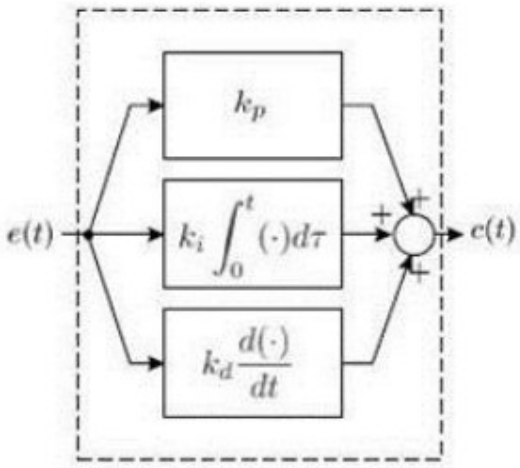


Sl. 1. Blok dijagram Sistema automatskog upravljanja sa digitalnim kontrolerom

Digitalni sistem automatskog upravljanja sadrži u opštem slučaju i analogne delove (objekat upravljanja). S obzirom da se digitalni sistemi opisuju diskretnim (diferencnim) jednačinama zadatak teorije digitalnih sitema je da nađe diskretni ekvivalent analognim delovima kako bi se vršila obrada isključivo diskretnih signala. Potrebno je naći diskretnu prenosnu funkciju sistema koja će obezbediti da sistem ima isti izlaz kao u slučaju kontinualne prenosne funkcije ali samo u trenucima odabiranja.

III. PID REGULATOR

Najčešće upotrebljavani kontroler u sistemima automatskog upravljanja je PID kontroler koji predstavlja kombinaciju Proporcionalnog Integracionog i Diferencijalng upravljanja. Razlog njegove rasprostranjenosti leži u jednostavnosti njegove primene.

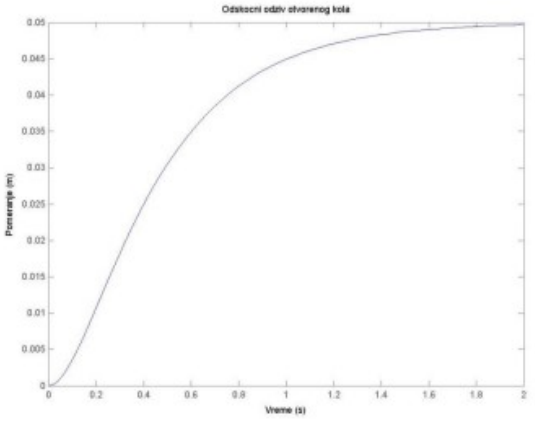


Sl. 2. Blok dijagram PID regulatora

U praksi se PID kontroleri izrađuju tako da svako od tri dejstava kontrolera bude sa podesivim parametrijma. Nakon jednostavne procedure podešavanja parametara najčešće se može postići zadovoljavajući odziv sistema čak i u slučaju kada nije poznat matematički model objekta upravljanja. U tom slučaju ovi kontroleri predstavljaju najbolje rešenje.

PID kontroleri su linearni pa daju slabe rezultate u slučaju nelinearnih sistema. Takođe su osetljivi na poremećaje visokih frekvencija što donekle može biti otklonjeno primenom nisko-propusnog filtera.

Da bi se analizirala priroda uticaja pojedinih komponti PID upravljačkog signala na sistem u celini pogodno je poznavati vremenski odziv sistema kada nema upravljanja odnono vremenski odziv otvorenog kola.



Sl. 3. Vremenski odziv otvorenog kola na jedinični odskočni signal

Jednačona PID regulatora po kojoj se računa upravljanje glasi:

$$u(t) = K_p + K_i \int_0^t e(t)dt + K_d \frac{de(t)}{dt}. \qquad (1)$$

U jednačini *u(t)* predstavlja vrednost upravljanja u vremenskom trenutku *t*. K_p, K_i i K_d su koeficijent proporcijalnog, integralnog i diferencijalnog dejstva tim redosledom, a *e(t) je* greška u vremenskom trenutku *t* dobijena razlikom referentnog i izlaznog signala.

Jednačina (1) je u kontinualnom domenu i u tom obliku nije upotrebljiva za implementaciju u mikroelektronici zato koristimo diskretnu brzinsku formu jednačine PID regulatora:

$$u(k) = u(k-1) + q_0 \cdot e(k) + q_1 \cdot e(k-1) + q_2 \cdot e(k-2). \qquad (2)$$

Za razliku od (1), u (2) se koriste diskretni odabirci u vremenu obeleženi sa *k*. Koeficijenti q_0, q_1 i q_2 se računaju kao:

$$q_0 = k_p + k_i. \qquad (3)$$

$$q_1 = k_p + k_i + 2 \cdot k_d. \qquad (4)$$

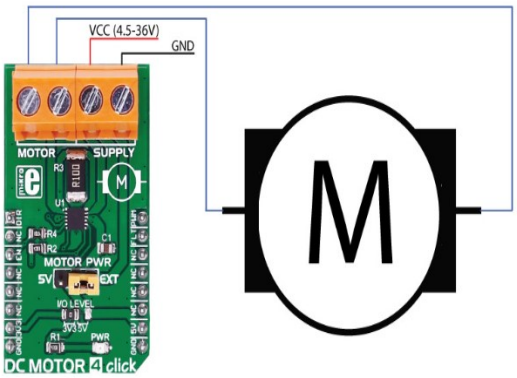
$$q_2 = k_d. \qquad (5)$$

k_p, k_i i k_d predstavljaju koeficijente proporcijalnog, integralnog i diferencijalnog upravljanja.

IV. DC MOTOR 4 CLICK

DC MOTOR 4 click [6] sadrži MAX14870 [5] motor drajver proizvođača Maxim Integrated. Click komunicira sa mikrokontrolerom preko sledećih pinova: PWM, AN, CS, i INT. Kratkospojnik na pločici se koristi za odabiranje eksternog ili internog napajanja. MAX14870 [5] motor drajver je male snage i jednostavno rešenje za upravljanje DC motorima i relejima naponima između 4.5 – 36V. Na click-u postoje dva zavrtna terminala od kojih se jedan kotisti za povezivanje motora, a drugi za eksterno napajanje ukoliko je potrebno.

Sl. 4. DC MOTOR 4 click – izgled [6]



Sl. 5. DC MOTOR 4 click – način povezivanja motora i napajanja [6]

Notes	Pin	mikro BUS				Pin	Notes
Rotation direction	DIR	1	AN	PWM	16	PWM	PWM Control Logic Input

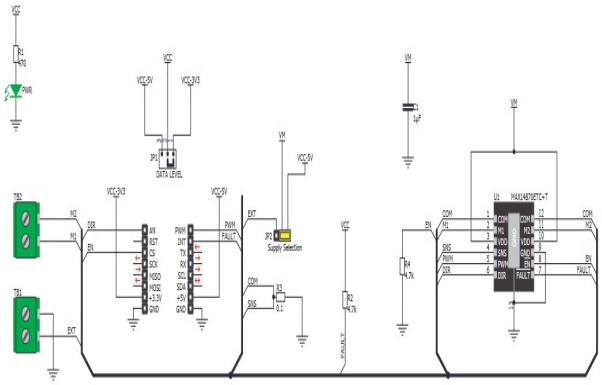
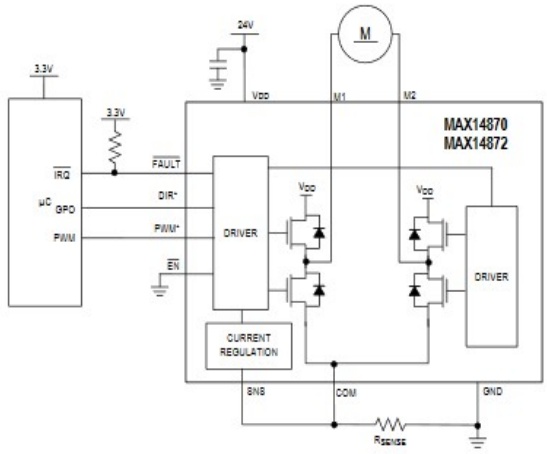
Sl. 6. DC MOTOR 4 click – pinout dijagram



Sl. 7. DC MOTOR 4 click – električna šema [6]



Sl. 8. MAX14870 motor drajver – šema [5]

V. Regulacija brzine obrtanja elektromotora

Za regulaciju brzine korišten je elektromotor čija je osovina bila pričvršćena za obrtni deo inkrementalnog enkodera sa 660 pozicija po krugu. Napajanje motora je vršeno koristeći eksterno napajanje od 5V preko DC MOTOR 4 click pločice koja je pretvarala DC napon u PWM signal koji je korišten za kontrolu brzine obrtanja motora. Signali sa A i B kanala enkodera su detektovani eksternim interaptom na pinovima RB0 i RB1. Pošto su signali sa enkodera samo impulsi, računanje brzine se vrši brojanjem impulsa u jedinici vremena. Referenca se zadaje putem UART-a u obrtajima po minuti.

Izračunavanje trenutne brzine obrtanja i vrednosti upravljanja se radi na svakih 100ms uz pomoć tajmerskog interapta. Za računanje upravljanja koristi se brzinska formula diskretnog PID regulatora pokazana ranije. Vrednosti upravljanja su softverski ograničene između 0 i 255 jer su to minimum i maksimum za podešavanje PWM duty cycle-a. Ispis vrednosti trenutne brzine, upravljanja i greške ce prosleđuje na UART terminal svaki sekund.

Podešavanje parametara PID regulatora vršeno je Zigler-Nicholsonovom metodom.

Brzina obrtanja elektro motora se račina preko formule:

$$obrtaji\_u\_minuti = \frac{broj\_impulsa}{660} \cdot 600 \quad (6)$$

Pod brojem impulsa misli se na impulse sa kanala A ili B inkrementalnog enkodera. Pošto se izračunavanje vrši svakih 100ms sve je pomnoženo sa 600 da bi se dobili obrtaji u minuti.

Zahvalnica

Zahvalio bih se Katedri za električna merenja, i katedri za automatiku fakulteta tehničkih nauka u Novom Sadu, za pruženo znanje potrebno za izradu ovog rada. Želim posebno da zahvalim profesoru Platonu Sovilju na pruženoj podršci u izradi ovog rada. Takođe bih da zahvalim kompaniji Mikroelektronika na tehničkoj podršci ovom projektu.

Prilog radnom uputstvu za etaloniranje silotermometara

Ivan Gutai, *Member, IEEE*, Bojan Vujičić, *Member, IEEE*, Nemanja Gazivoda, *Member, IEEE*

***Apstrakt*—U ovom radu se daje jedan primer postupka etaloniranja silotermometara, koje se sprovodi na objektu na terenu. Prikazane su najbolje mogućnosti merenja, opisana je priprema za merenje, navedena je merna oprema koja se koristi, opisani su postupci merenja koje treba sprovesti i prikazana je obrada dobijenih rezultata.**

***Ključne reči*—Postupak etaloniranja silotermometara; ISO 17025; Metrologija**

I. Uvod

Temperatura je fizička veličina koja predstavlja stepen zagrejanosti tela. Temperatura je povezana sa termičkim kretanjem molekula ili atoma, tj. sa termodinamičkim stanjem tela i njegovom unutrašnjom energijom. Fizičke veličine kao što su masa, dužina, i druge označavaju se kao ekstenzivne ili parametarske, jer se sa povećanjem objekta povećava i njihova vrednost. Za razliku od ovih veličina, temperatura je intenzivna ili aktivna veličina. Njen intenzivni karakter ogleda se u tome što će prilikom deljenja tela na više delova svaki deo zadržati temperaturu tog tela. Drugim rečima, temperatura nema svojstvo aditivnosti. Za temperaturu se ne može izgraditi delitelj ili sabirač. Zbog toga se etalon temperature ne može praviti na način kako se to radi za ekstenzivne veličine. U skladu sa drugim zakonom termodinamike, pri uzajamnom delovanju dva tela sa različitim temperaturama prelazi toplota od tela sa većom energijom na telo sa manjom energijom. Prelaženje toplote vrši se kondukcijom, konvekcijom i radijacijom. Promena toplotnog stanja tela koja tada nastaje praćena je popratnim efektima i fenomenima, kao što su: dilatacija, ekspanzija, termoelektricitet, zračenje, itd. Zbog propratnih efekata menjaju se određena fizička svojstva tela, tj. odgovarajuće veličine: dužina, volumen, termoelektrična sila, električni otpor i dr. Ovo su termometrijske veličine, jer se njihovim direktnim merenjem dolazi do vrednosti temperature. Iz ovoga se zaključuje da je temperaturu moguće izmeriti samo posrednim putem, preko termometrijskih veličina, koje su podložne direktnom merenju i u funkcionalnoj su vezi sa temperaturom. Senzor za merenje temperature obično se naziva termometrom, a oblast merenja temperature termometrijom. Temperatura je najčešće merena veličina u tehnološkim procesima i na nju otpada oko 60% svih merenja u toj oblasti. Veliki je značaj merenja temperature i u drugim oblastima nauke i tehnike, u medicini, u svakodnevnom životu. [1].

Ovaj rad ima cilj da prikaže način na koji Laboratorija za metrologiju izvršava etaloniranja silotermometara. Svi termini i definicije su u skladu sa SRPS ISO/IEC 9000:2001, SRPS ISO/IEC 17025:2006 i Međunarodnim rečnikom osnovnih i opštih termina u metrologiji.

II. Priprema za rad

A. *Merna nesigurnost*

Merna nesigurnost iskazana u ovom radu je proširena merna nesigurnost, gde je standardna merna nesigurnost pomnožena faktorom obuhvata k = 2, što za slučaj normalne raspodele greške odgovara verovatnoći od približno 95 %. Najbolje mogućnosti etaloniranja su prikazane u Tabeli I.

TABELA I
NAJBOLJE MOGUĆNOSTI ETALONIRANJA

Veličina	Predmet etaloniranja	Opseg	Merna nesigurnost
Temperatura	Silotermometri	od -30 °C do 70 °C	≤ 0,5 °C

B. *Priprema za etaloniranje*

Priprema za etaloniranje obuhvata detaljno upoznavanje objekta etaloniranja na osnovu priložene dokumentacije, eventualnih prethodnih iskustava sa ranijih etaloniranja i ostalih informacija u kontaktima sa vlasnikom objekta, proizvođačem i/ili serviserom sistema silotermometara.

C. *Vizuelni pregled*

Vizuelnim pregledom se utvrđuje usaglašenost oznaka, opšte stanje objekta etaloniranja i konstatuju se eventualna oštećenja. Konstatuje se i da li ima ćelija bez sajli.

D. *Provera referentnih uslova etaloniranja*

Referentni uslovi za merenje su: temperatura okoline od 10 °C do 30 °C i relativna vlažnost vazduha od 40 % do 80 %.

III. Merna oprema

Oprema neophodna za etaloniranje silotermometara navedena je u Tabeli II.

Ivan Gutai – Laboratorija za metrologiju, Fakultet tehničkih nauka, Novi Sad, Srbija (e-mail: gutai@uns.ac.rs).

Bojan Vujičić – Laboratorija za metrologiju, Fakultet tehničkih nauka, Novi Sad, Srbija (e-mail: bojanvuj@uns.ac.rs).

Nemanja Gazivoda – Laboratorija za metrologiju, Fakultet tehničkih nauka, Novi Sad, Srbija (e-mail: nemanjagazivoda@uns.ac.rs).

TABELA II
OPREMA NEOPHODNA ZA ETALONIRANJE SILOTERMOMETARA

Oznaka	Naziv	Tip
MΩ	Instrument za merenje električne otpornosti izolacije	Iskra MA 2075
R_s	Dekadna kutija otpornosti	GenRad, Model 1433G
Ω	Digitalni multimetar	Fluke, Model 87V

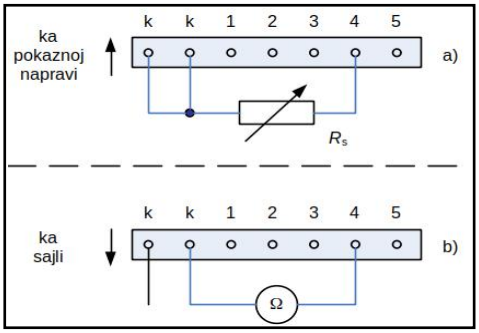
IV. POSTUPAK MERENJA

A. *Izbor sajli*

Na osnovu pokazivanja temperatura sa svih mernih mesta, konstatuju se eventualne smetnje na pojedinim kanalima (prekidi veza sa senzorima ili njihova neispravnost). Konstatuju se i eventualne velike razlike u merenim temperaturama na bliskim mernim mestima i traže se uzroci za to. Izaberu se kritične sajle i zabeleže se temperature Tm1(i) (i – nivo senzora u sajli) koje odgovaraju senzorima temperature na izabranim sajlama.

B. *Merenja na nadsilosnoj galeriji*

Sa kompetentnom osobom (serviser i/ili radnik silosa) odlazi se na nadsilosnu galeriju. Utvrđuju se merna mesta odabranih ćelija, redosled senzora, kompenzacioni otpornici, itd. Odspoji se sajla od multipleksera (pokazne naprave) i pristupa se merenjima prema šemi na slici 1.



Sl 1. Šema veza za a) etaloniranje pokazne naprave silotermometra; b) proveru ispravnosti senzora temperature

a) Na kontakte prema pokaznoj napravi priključuje se dekadna kutija otpornosti na kojoj je postavljena etalonska otpornost R_s. Imajući u vidu tip senzora temperature (Pt-100, Pt-1000, NTC, ...), vrednostima R_s dodeljuju se vrednosti temperature T_{s2}. Na pokaznoj napravi očitavaju se pokazivanje $T_{m2}(i)$. Vrednosti R_s biraju se tako da odgovaraju nazivnim temperaturama etaloniranja: 20 °C, 30 °C , 40 °C i 50 °C. Rezultati merenja se unose u Tabelu III.

b) Na kontakte prema senzoru temperature priključuje se merilo otpornosti (digitalni multimetar). Izmeri se otpornost kompenzacionog otpornika R_k. Zatim se izmere otpornosti senzora temperature $R_T(i)$ i serijski vezanog kompenzacionog otpornika R_k. Od tako izmerenih otpornosti oduzmu se vrednosti otpornosti kompenzacionog otpornika R_k. Imajući u vidu tip senzora temperature, dobijenim vrednostima pridružuju se temperature $T_{s1}(i)$. Porede se tako izračunata temperature sa temperaturama $T_{m1}(i)$, izmerenim pomoću pokazne naprave. Rezultati merenja se unose u Tabelu IV.

TABELA III
Tabela za evidenciju rezultata etaloniranja pokazne naprave silotermometra

Kompenzaciona otpornost R_k	Nivo senzora i	$R_T + R_k$	Temperatura odgovarajuća izmerenoj otpornosti T_{s1}	Očitanje pokazne naprave $T_{m1}(i)$
Ω		Ω	°C	°C

			...		

C. *Merenje otpornosti izolacije*

Merenja otpornosti izolacije se sprovodi tako što se krajevi (dovodne žice) otpornog temperaturnog senzora kratko vežu i zajedno dovedu na jedan kraj instrumenta za merenje električne otpornosti izolacije (megaommetra). Drugi kraj megaommetra se krokodil štipaljkom spoji na uzemljenu tačku silosa. Ispitni napon megaommetra treba da bude jednosmerni napon u granicama od 10 V do 100 V.

D. *Metod etaloniranja*

Etaloniranje silotermometra vrši se metodom poređenja. Očitanja/nominalne vrednosti na instrumentu koji se etalonira porede se sa očitanjima na etalonskom instrumentu.

E. *Etaloniranje pokazne naprave*

Model izračunavanja greške izvora $G(T)$ je dat jednačinom (1):

$G(T)$ Greška pokazne naprave;

T_x Očitanje temperature na pokaznoj napravi;

δT_x Korekcija temperature očitane na pokaznoj napravi, zbog konačne rezolucije displeja pokazne naprave.

R_s Nazivna otpornost etalona otpornosti.

k_{RT} Korekcija etalonske otpornosti, iz sertifikata o etaloniranju etalon otpornika.

k_T Korekcija etalonske otpornosti, zbog promene etalonske otpornosti u zavisnosti od temperature okoline.

α Temperaturski koeficijent otpornosti.

$R(0)$ Otpornost na temperaturi od 0 °C temperaturske sonde za koju je predviđena pokazna naprava.

$$G(T) = (T_x + \delta T_x) - T_s(R_s + k_{RT} + k_T) \approx (T_x + \delta T_x) - \frac{1}{\alpha}\left(\frac{R_s + k_{RT} + k_T}{R(0)} - 1\right) \quad (1)$$

U Tabeli V je dat primer budžeta nesigurnosti etaloniranja.

TABELA V

***Apstrakt*—U radu je izložen primer postupka etaloniranja pokaznih naprava termometara sa otpornim sondama metodom poređenja u uslovima unutar i u uslovima van metrološke laboratorije. Prikazane su najbolje mogućnosti merenja, opisana je priprema za merenje, navedena je merna oprema koja se koristi, opisani su postupci merenja koje treba sprovesti i prikazana je obrada dobijenih rezultata**

***Ključne reči*—termometar; etalonski otpornik; multimetar; etaloniranje; merna nesigurnost; budžet merne nesigurnosti; metrologija.**

I. Uvod

Ovaj rad ima cilj da prikaže jedan od načina na koji Laboratorija za metrologiju Fakulteta tehničkih nauka (FTN) u Novom Sadu izvršava etaloniranje pokaznih naprava termometara. Krajnji proizvod etaloniranja je dokument Uverenje o etaloniranju koje se izdaje klijentu saglasno dokumentovanom sistemu kvaliteta.

Postupak etaloniranja pokaznih naprava termometara sa otpornim sondama određen je radnim uputstvom izrađenim od strane tima saradnika Laboratorije za metrologiju. U radnom uputstvu, svi termini i definicije su u skladu sa SRPS ISO/IEC 9000:2015, SRPS ISO/IEC 17025:2017 i Međunarodnim rečnikom osnovnih i opštih termina u metrologiji.

U ovom radu obrađeni su termometri sa otpornim sondama (RTD). Termometri sa otpornim sondama zasnivaju se na merenju električne otpornosti ugrađene sonde koja zavisi od temperature. Etaloniranje pokazne naprave vrši se metodom poređenja. Na pokaznu napravu se, umesto temperaturske sonde, priključuje etalonski otpornik za simuliranje otpornih sondi. Očitanja na pokaznoj napravi termometra porede se sa izračunatim vrednostima temperature, koje odgovaraju zadatim etalonskim vrednostima otpornosti.

Za proračun merne nesigurnosti određivanja greške pokazne naprave ne uzimaju se u obzir otpornosti priključnih vodova.

II. Merne mogućnosti i merna oprema

U Tabeli I prikazane su merne mogućnosti etaloniranja pokaznih naprava termometara sa otpornim sondama, raspoloživom opremom Laboratorije.

TABELA I
Merne mogućnosti

Veličina	Predmet etaloniranja	Opseg	Merna nesigurnost*
Temperatura	Pokazna naprava termometara sa otpornom sondom (unutar laboratorije)	od -200 °C do +50 °C	0,010 °C
		od +50 °C do +500 °C	0,040 °C
	Pokazna naprava termometara sa otpornom sondom (van laboratorije)	od -200 °C do +50 °C	0,15 °C
		od +50 °C do +500 °C	0,50 °C

*Merna nesigurnost je proširena merna nesigurnost, gde je standardna merna nesigurnost pomnožena faktorom obuhvata k=2, što za slučaj normalne raspodele greške odgovara verovatnoći od približno 95 %.

Merna oprema

U Tabeli II prikazani su referentni etaloni Laboratorije.

TABELA II
Referentni etaloni

Naziv	Tip
Digitalni multimetar	Hewlett Packard 3458A

Radni etaloni Laboratorije koji se koriste za etaloniranje pokaznih naprava su prikazani u Tabeli III.

TABELA III
Radni etaloni

Naziv	Tip
Digitalni multimetar	Fluke 8846A
Dekadna kutija otpornosti	GR 1433-G
	GR 1433-H

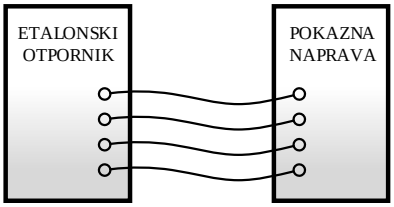
III. ETALONIRANJE UNUTAR LABORATORIJE ZA METROLOGIJU

Priprema za etaloniranje u Laboratoriji podrazumeva vizuelni pregled objekta etaloniranja, konstataciju da je objekt pripremljen za etaloniranje i proveru referentnih uslova etaloniranja. Potrebno da objekt etaloniranja bude u Laboratoriji najmanje 12 sati pre početka etaloniranja, da bi se njegova temperatura izjednačila sa temperaturom okoline. Vizuelnim pregledom se utvrđuje opšte stanje objekta etaloniranja i konstatuju se eventualna oštećenja. Utvrđuje se, takođe, i postojanje dokumentacije o objektu etaloniranja, relevantne za etaloniranje. Referentni uslovi za merenje u Laboratoriji su:

Temperatura okoline: (23 ± 2) °C;
Relativna vlažnost vazduha: (45 ± 15) %.

Referentni uslovi u Laboratoriji se održavaju stalno, i podrazumeva se ispunjenje navedenih zahteva neposredno pre merenja.

Analiziraće se slučaj kada je otporna sonda izrađena od metala (Pt-100, Pt-1000 i sl.).



Sl. 1. Blok šema etaloniranja pokazne naprave termometra sa otpornom sondom

Model izračunavanja greške E_X pokazne naprave je:

$$E_X = (T_X + \delta T_X) - T(R_S + \delta R_S) \quad (1)$$

gde je:

T_X Pokazivanje pokazne naprave;
δT_X Korekcija očitanja pokazne naprave, zbog konačne rezolucije očitavanja;
$T(R)$ Temperatura koja odgovara otpornosti R , definisana standardom ili od strane proizvođača pokazne naprave;
R_S Etalonska otpornost kojom se simulira otporna sonda;
δR_S Korekcija zbog netačnosti merenja etalonske otpornosti;

Vrednost etalonske otpornost R_S meri se digitalnim multimetrom sa granicama greške G_{Rs} određene specifikacijom proizvođača. Smatra se da gustina raspodele verovatnoće greške merenja digitalnim multimetrom kao i raspodela greške očitavanja pokazne naprave imaju ravnomernu raspodelu.

Standardna merna nesigurnost očitanja pokazne naprave zbog konačne rezolucije očitavanja određena je formulom:

$$u(\delta T_X) = \frac{LSD}{2\sqrt{3}} \quad (2)$$

gde je LSD (*Least Significiant Digit*) rezolucija displeja pokazne naprave.

Standardna merna nesigurnost koja potiče od digitalnog multimetra određena je izrazom:

$$u(\delta R_S) = \frac{G_{Rs}}{\sqrt{3}} \quad (3)$$

Koeficijenti osetljivosti su:

$$c_1 = \frac{\partial E_X}{\partial \delta T_X} = 1 \quad (4)$$

$$c_2 = \frac{\partial E_X}{\partial \delta R_S} = -\frac{\partial T(R_S + \delta R_S)}{\partial \delta R_S} \quad (5)$$

Merna nesigurnost određivanja greške etaloniranja pokazne naprave predviđene za rad sa otpornim sondama:

$$u(E_X) = \sqrt{[c_1 \cdot u(\delta T_X)]^2 + [c_2 \cdot u(\delta R_S)]^2} \quad (6)$$

Proširena merna nesigurnost U definisana je sa:

$$U = k \cdot u(E_X) \quad (7)$$

Etalonirana je pokazna naprava, za opseg temperatura od -50 °C do +600 °C, sa rezolucijom od LSD=0,01 °C , predviđena da se na nju, četvorožično, priključi otporna sonda Pt-100. Vrednost etalonskog otpornika kojim se simulira otporna sonda izmerena je digitalnim multimetrom Hewlett Packard 3458A.

			Proširena merna nesigurnost (k=2)				0,012 °C

IV. ETALONIRANJE VAN LABORATORIJE ZA METROLOGIJU

Priprema za etaloniranje podrazumeva proveru metroloških karakteristika etalonskog sistema pre odlaska na mesto etaloniranja, prevoz do mesta etaloniranja, vizuelni pregled objekta etaloniranja, konstataciju da je objekt pripremljen za etaloniranje i proveru referentnih uslova etaloniranja. Da bi se smanjili rizici tokom prenošenja opreme do i od mesta etaloniranja, pre i posle prenosa vrši se provera osnovnih metroloških karakteristika etalona. Po pravilu, oprema za etaloniranje do i od mesta etaloniranja prenosi se putničkim automobilom.

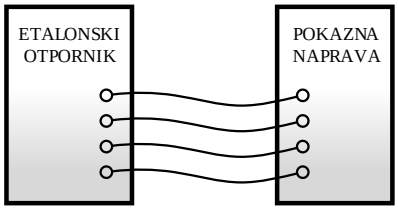
Za etaloniranja van Laboratorije je potrebno da objekt etaloniranja i etalonska oprema budu u prostoru namenjenom za etaloniranje najmanje jedan sat pre početka etaloniranja, da bi se njihova temperatura približno izjednačila sa temperaturom okoline. Za etaloniranje van Laboratorije utvrđuje se i opšte stanje prostora u kome treba da se obavi etaloniranje: prostor mora da je čist, bez prašine i drugih agensa koji mogu da deluju na mernu opremu, da bude suv i da se u njemu ne odvijaju druge aktivnosti koje mogu da nepovoljno utiču na postupak etaloniranja. Vizuelnim pregledom se utvrđuje opšte stanje objekta etaloniranja i konstatuju se eventualna oštećenja. Utvrđuje se, takođe, i postojanje dokumentacije o objektu etaloniranja, relevantne za etaloniranje.

Referentni uslovi za merenje van Laboratorije su:

Temperatura okoline: 10 °C do 30 °C;
Relativna vlažnost vazduha: 40 % do 80 %.

Neposredno pre merenja podrazumeva se ispunjenje navedenih referentnih uslova.

Analiziraće se slučaj kada je otporna sonda izrađena od metala (Pt-100, Pt-1000 i sl.).



Sl. 2. Blok šema etaloniranja pokazne naprave termometra sa otpornom sondom

Model izračunavanja greške E_X pokazne naprave je:

$$E_X = (T_X + \delta T_X) - T(R_S + \delta R_S + \delta R_{S-temp}) \qquad (8)$$

gde je:

T_X Pokazivanje pokazne naprave;
δT_X Korekcija očitanja pokazne naprave, zbog konačne rezolucije očitavanja;
$T(R)$ Temperatura koja odgovara otpornosti R , definisana standardom ili od strane proizvođača pokazne naprave;
R_S Etalonska otpornost kojom se simulira otporna sonda;
δR_S Korekcija zbog netačnosti merenja etalonske otpornosti;
$\delta R_{S\text{-temp}}$ Korekcija zbog netačnosti merenja etalonske otpornosti ako temperatura okoline izlazi van referentnog opsega temperatura etalonskog merila otpornosti;

Vrednost etalonske otpornost R_S meri se digitalnim

multimetrom sa granicama greške G_{Rs} određene specifikacijom proizvođača. Ako ambijentalna temperatura izađe van referentnog opsega multimetra, granice grešaka merenja se povećavaju zbog uticaja dodatne greške $G_{Rs\text{-}temp}$, koja je posledica ambijentalne temperature. Smatra se da gustina raspodele verovatnoće greške merenja digitalnim multimetrom kao i raspodela greške očitavanja pokazne naprave imaju ravnomernu raspodelu.

Standardna merna nesigurnost očitanja pokazne naprave zbog konačne rezolucije očitavanja određena je formulom:

$$u(\delta T_X) = \frac{LSD}{2\sqrt{3}} \tag{9}$$

Standardna merna nesigurnost koja potiče od digitalnog multimetra određena je izrazom:

$$u(\delta R_S) = \frac{G_{Rs}}{\sqrt{3}} \tag{10}$$

Standardna merna nesigurnost koja potiče od dodatne greške multimetra usled ambijentalne temperature je:

$$u(\delta R_{S-temp}) = \frac{G_{Rs-temp}}{\sqrt{3}} \tag{11}$$

Koeficijenti osetljivosti su:

$$c_1 = \frac{\partial E_X}{\partial \delta T_X} = 1 \tag{12}$$

$$c_2 = \frac{\partial E_X}{\partial \delta R_S} = -\frac{\partial T(R_S + \delta R_S + \delta R_{S-temp})}{\delta R_S} \tag{13}$$

$$c_3 = \frac{\partial E_X}{\partial \delta R_{S-temp}} = -\frac{\partial T(R_S + \delta R_S + \delta R_{S-temp})}{\delta R_{S-temp}} \tag{14}$$

Merna nesigurnost određivanja greške etaloniranja pokazne naprave predviđene za rad sa otpornm sondama:

$$u(E_X) = \sqrt{[c_1 \cdot u(\delta T_X)]^2 + [c_2 \cdot u(\delta R_S)]^2 + [c_3 \cdot u(\delta R_{S-temp})]^2} \tag{15}$$

Etalonirana je pokazna naprava, za opseg temperatura od -50 °C do +600 °C, sa rezolucijom od LSD=0,01 °C, predviđena da se na nju, četvorožično, priključi otporna sonda Pt-100. Vrednost etalonskog otpornika kojim se simulira otporna sonda izmerena je digitalnim multimetrom Fluke 8846A.

			Proširena merna nesigurnost (k=2)				0,013 °C

V. ZAKLJUČAK

Etaloniranje pokaznih naprava termometara sa otpornim sondama saglasno je dokumentovanom sistemu kvaliteta Laboratorije za metrologiju. Opisana metoda etaloniranja je jedna od metoda koje se koriste u Laboratoriji za etaloniranje pokaznih naprava termometara. Napredak u tačnosti merenja do danas dostigao je nivo da rezolucija i merna nesigurnost instrumenata prednjače ispred mogućnosti apsolutnih merenja.

Postalo je teško odgovoriti na pitanja šta nam znači merenje otpornosti sa rezolucijom 0,001 ppm kad je om (Ω) definisan sa mernom nesigurnošću reda 0,2 ppm [3]. Međutim, merna nesigurnost opisane metode ispunjava većinu zahteva klijenata Laboratorije, kada su u pitanju pokazne naprave termometara.

ZAHVALNICA

Ovaj rad je delom podržan od strane projekta ELEMEND (šifra projekta: 585681-EEP-1-2017-EL-EPPKA2-CBHE-JP).

ABSTRACT

The paper presents an example of the method of calibration temperature indicators with resistive probes by comparison method, in conditions inside and outside the metrology laboratory. The best measurement posibilities and measurement equipment are presented, the preparation for measurements and measurement procedures is described, and processing of the obtained results is shown.

***Apstrakt*— U ovom radu je dat primer postupka etaloniranja termometara sa direktnim očitavanjem u Laboratoriji za metrologiju Fakulteta tehničkih nauka u Novom Sadu. Prikazane su najbolje mogućnosti merenja, opisana je priprema za merenje i navedena je merna oprema koja je korišćena. Opisani su postupci merenja koji treba da se sprovedu i prikazana je obrada dobijenih rezultata. Dati su primeri koji ilustruju primenu ovog uputstva. Svi termini i definicije su u skladu sa SRPS ISO/IEC 9000:2001, SRPS ISO/IEC 17025:2017 i Međunarodnim rečnikom osnovnih i opštih termina u metrologiji.**

***Ključne reči*—** merna oprema; etaloniranje; metrologija; termometar; merna nesigurnost.

I. Uvod

Uređaji za merenje temperature ili temperaturnog gradijenta nazivaju se termometri. Međusobno se razlikuju kako po principu na kojem se zasniva njihov rad, tako i prema mernom području. Proces etaloniranja koji prethodi izdavanju uverenja o etaloniranju je u upotrebi u industriji, laboratorijama, ocenjivanju usaglašenosti tela i preduzećima, kako bi zadovoljili zahteve standarda. Uverenje o etaloniranju je sredstvo kojim se obezbeđuje dokaz sledivosti merenja.

U Tabeli I su prikazane merne mogućnosti etaloniranja termometara sa direktnim očitavanjem u Laboratoriji za metrologiju Fakulteta tehničkih nauka u Novom Sadu (u daljem tekstu samo Laboratorija). Merna nesigurnost iskazana u ovom radu je proširena merna nesigurnost, kod koje je standardna merna nesigurnost pomnožena faktorom obuhvata $k = 2$, što za slučaj normalne raspodele greške odgovara verovatnoći od približno 95%.

TABELA I
NAJBOLJE MOGUĆNOSTI ETALONIRANJA U LABORATORIJI

Predmet etaloniranja	Temperaturni opseg	Merna nesigurnost
Stakleni termometri punjeni tečnošću, otpornički termometri, termometri sa termoparom	0 °C	0.05 °C
Stakleni termometri punjeni tečnošću, otpornički termometri, termometri sa termoparom	- 40 °C do 250 °C	0.10 °C
Stakleni termometri punjeni tečnošću, otpornički termometri, termometri sa termoparom	250 °C do 500 °C	2.0 °C
Termometri sa termoparom	500 °C do 1200 °C	3.5 °C

II. Priprema za rad

Priprema za etaloniranje u Laboratoriji podrazumeva vizuelni pregled objekta etaloniranja, konstataciju da je objekt pripremljen za etaloniranje i proveru referentnih uslova etaloniranja. Potrebno da objekt etaloniranja bude u Laboratoriji najmanje dvanaest sati pre početka etaloniranja, da bi se njegova temperatura izjednačila sa temperaturom okoline. Vizuelnim pregledom se utvrđuje opšte stanje objekta etaloniranja i konstatuju se eventualna oštećenja. Utvrđuje se, takođe, i postojanje dokumentacije o objektu etaloniranja, relevantne za etaloniranje.

Referentni uslovi za merenje u Laboratoriji su:

1. Temperatura okoline: (23 ± 2) °C
2. Relativna vlažnost vazduha: (45 ± 15)%.

Referentni uslovi u Laboratoriji se održavaju stalno, a provera podrazumeva ispunjenje navedenih zahteva neposredno pre merenja.

III. Merna oprema

Oprema, koja je neophodna za etaloniranje termometara sa direktnim očitavanjem, je navedena u Tabelama II, III i IV.

TABELA II

Tabela V daje pregled mogućnosti etaloniranja raspoloživom opremom Laboratorije u opsegu temperatura – 50 °C do 1200 °C. Plava polja ukazuju na nemogućnost pojedinih kombinacija.

TABELA V
PRIKAZ MOGUĆNOSTI ETALONIRANJA RASPOLOŽIVOM OPREMOM LABORATORIJE

Etalon / Sredina	5187 SA & HP 3458A	S(T9) & HP 3458A	884X-RTD & 8846A*	S(T1) & 8846A*	Kalibrator temperature
AVM (alkohol)	-50 °C do 25 °C				
AVM (ulje)	25 °C do 250 °C				
9101	0 °C		0 °C		0 °C
9103	-25 °C do 140 °C	-25 °C do 140 °C	-25 °C do 140 °C	-25 °C do 140 °C	-25 °C do 140 °C
9140	35 °C do 350 °C	35 °C do 350 °C	35 °C do 300 °C	35 °C do 350 °C	35 °C do 350 °C
9141	50 °C do 650 °C	50 °C do 650 °C	50 °C do 300 °C	50 °C do 650 °C	50 °C do 650 °C
Pegasus 1200	150 °C do 650 °C	150 °C do 1064 °C	150 °C do 300 °C	150 °C do 1064 °C	150 °C do 1200 °C
Peć	100 °C do 650 °C	100 °C do 1064 °C			

Najbolje mogućnosti etaloniranja u opsegu temperatura - 50 °C do 1200 °C moguće je postići kombinacijom raspoloživih etalona i sredina etaloniranja, kao što je prikazano u Tabeli VI. Plava polja ukazuju ili na nemogućnost pojedinih kombinacija ili na kombinacije koje ne daju najbolje mogućnosti etaloniranja. Neka od plavih polja mogu biti aktivirana u slučaju da se za sonde etaloniranih termometara postavljaju posebni zahtevi.

TABELA VI
PREGLED KOMBINACIJA ETALONA I SREDINA ETALONIRANJA RASPOLOŽIVOM OPREMOM LABORATORIJE KOJE DAJU NAJBOLJE MOGUĆNOSTI ETALONIRANJA

Etalon / Sredina	5187 SA & HP 3458A	S(T9) & HP 3458A	884X-RTD & 8846A*	S(T1) & 8846A*	Kalibrator temperature

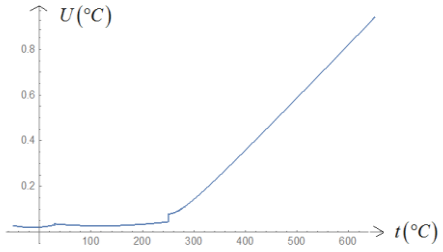
Pegasus 1200				650 °C do 1064 °C	1064 °C do 1200 °C
Peć	250 °C do 650 °C	650 °C do 1064 °C			

Imajući u vidu metrološke karakteristike etalona i svojstva zona etaloniranja, grafički smo predstavili najbolje mogućnosti etaloniranja u funkciji temperature etaloniranja i u zavisnosti od izbora etalonskog sistema.

A. – 50 °C *do* 650 °C

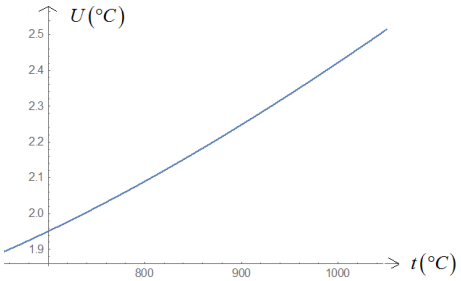
Etalonski sistem, prikazan na Sl. 1, sastoji se iz referentnog platinskog otporničkog termometra Tinsley 5187 SA i referentnog digitalnog multimetra HP 3458A. Za temperature etaloniranja u granicama – 50 °C do 25 °C, sredina etaloniranja je alkohol, u granicama 25 °C do 250 °C, sredina etaloniranja je silikonsko ulje i u granicama 250 °C do 650 °C, sredina etaloniranja je vazduh (peć).



Sl. 1. Proširena merna nesigurnost etaloniranja za faktor obuhvata $k = 2$ u zavisnosti od temperature, za etalonski sistem koji se sastoji od referentnog platinskog otporničkog termometra Tinsley 5187 SA i referentnog digitalnog multimetra HP 3458A

B. 650 °C *do* 1050 °C

Etalonski sistem, prikazan na Sl. 2, sastoji se iz referentnog termopara S tipa (Termotehna) i referentnog digitalnog multimetra HP 3458A. Sredina etaloniranja je vazduh (peć).



Sl. 2. Proširena merna nesigurnost etaloniranja za faktor obuhvata $k = 2$ u zavisnosti od temperature, za etalonski sistem koji se sastoji od referentnog termopara (Termotehna T9) i referentnog digitalnog multimetra HP 3458A

C. 1064 °C *do* 1200 °C

Etalon je suvo kupatilo Pegasus 1200. Proširena merna nesigurnost etaloniranja je ocenjena na 3.5 °C. Etaloniranje termometara vrši se metodom poređenja. Očitanja na etaloniranom termometru porede se sa očitanjima na etalonskom termometru.

IV. Etaloni

Laboratorija raspolaže opremom kojom je moguće realizovati u osnovi tri međusobno različita etalonska merna sistema.

A. Etalonski sistem sa otporničkom sondom i digitalnim multimetrom

Odstupanje (greška) pokazivanja rezultata merenja temperature etaloniranog termometra (DUT engl. *Device Under Test*) od temperature koju pokazuje etalonski merni sistem sa PRT sondom, modeluje se izrazom:

$$E_{DUT}=(T_{DUT}+\delta T_{DUT}) - \\ -(T(R_s+\delta R_s+k_{Rs})+k_{PRT}+k_{DriftPRT}+k_{Stab}+k_{HomR}+k_{HomA}),$$

gde je:

T_{DUT} Pokazivanje (aritmetička sredina pokazivanja) DUT; Analitički izraz za njenu nesigurnost je $u_{T_{DUT}}=\frac{S_{T\,DUT}}{\sqrt{n_{T\,DUT}}}$;

$S_{T\,DUT}$ Standardno odstupanje niza pojedinačnih očitanja DUT, a $n_{T\,DUT}$ broj tih očitanja;

δT_{DUT} Korekcija očitanja DUT, zbog konačne rezolucije očitavanja. Ocena korekcije je 0 °C. Standardna nesigurnost korekcije očitanja određena je formulom $u_{\delta T\,DUT}=\frac{LSD}{2\sqrt{3}}$, gde je *LSD* rezolucija displeja DUT;

R_s Otpornost etalonske sonde, PRT, izmerene etalonskim merilom otpornosti;

$T(R_s)$ Temperatura etaloniranja (aritmetička sredina niza očitanja), kao funkcija otpornosti R_s, definisana standardom, ili od strane proizvođača PRT, ili iz odgovarajućeg uverenja o etaloniranju. Njena nesigurnost je $u_{T(R_s)}=\frac{S_{Rs}}{\sqrt{n_{Rs}}}$, gde je S_{Rs} standardno odstupanje niza pojedinačnih očitanja R_s, a n_{Rs} broj tih očitanja;

δR_s Korekcija očitanja otpornosti R_s, zbog konačne rezolucije očitavanja;

k_{Rs} Korekcija merenja otpornosti R_s, zbog netačnosti merenja otpornosti. Ocena korekcije se preuzima iz uverenja o etaloniranju merila otpornosti. Nesigurnost korekcije se preuzima iz uverenja o etaloniranju ili se koriste podaci o tačnosti merila otpornosti, datih od strane proizvođača;

k_{PRT} Korekcija merenja temperature etaloniranja, zbog netačnosti PRT. Nesigurnost korekcije se preuzima iz uverenja o etaloniranju ili se koriste podaci o tačnosti merila otpornosti, datih od strane proizvođača;

$k_{DriftPRT}$ Korekcija merenja temperature etaloniranja, zbog drifta PRT;

k_{Stab} Korekcija merenja temperature etaloniranja, zbog nestabilnosti temperature etaloniranja tokom vremena etaloniranja;

k_{HomR} Korekcija merenja temperature etaloniranja, zbog radijalne nehomogenosti temperature u zoni etaloniranja;

k_{HomA} Korekcija merenja temperature etaloniranja, zbog aksijalne nehomogenosti temperature u zoni etaloniranja.

Analizu merne nesigurnosti rezultata etaloniranja DUT (merila temperature sa direktnim očitavanjem), kada se etalon sastoji od otporničke sonde (PRT) i digitalnog multimetra, prikazali smo u primerima u obliku budžeta merne nesigurnosti.

Primer 1.

Etaloniran je stakleni termometar punjen živom, mernog opsega 150 °C do 200 °C i vrednošću najmanjeg podeoka od 0.1 °C. Etalonski sistem se sastoji od platinskog otporničkog termometra, model 5187 SA, i digitalnog multimetra, model 8846A. Sredina etaloniranja je temperaturno kupatilo sa silikonskim uljem. Prikaz budžeta nesigurnosti rezultata etaloniranja prikazan je u Tabeli VII.

Budući da je objekt etaloniranja stakleni termometar punjen tečnošću, model greške termometra, koji je prikazan u (1), dopunjen je korekcijom očitanja temperature termometra, k_{DP}, zbog delimičnog potapanja termometra u ulje, kako je opisano u Referentnom dokumentu za etaloniranje ovakve vrste termometara. Kombinovana merna nesigurnost rezultata etaloniranja $u(e_{DUT})$ je 0.11 °C, a proširena merna nesigurnost rezultata etaloniranja $U(e_{DUT})$ za faktor obuhvata $k = 2$ iznosi 0.22 °C .

TABELA VII
PRIKAZ BUDŽETA MERNE NESIGURNOSTI ETALONIRANJA STAKLENOG TERMOMETRA IZ PRIMERA 1

Veličina	Simbol	Ocena	Nesigurnost	Tip	Raspodela	Osetljivost	Doprinos

Korekcija merenja temperature etaloniranja, zbog radijalne nehomogenosti temperature u zoni etaloniranja (°C)	k_{HomR}	0	14E-3	B	R	-1	0.014
Korekcija merenja temperature etaloniranja, zbog aksijalne nehomogenosti temperature u zoni etaloniranja (°C)	k_{HomA}	0	14E-3	B	R	-1	0.014
Greška DUT	E_{DUT}	0.245					0.112

B. *Etalonski sistem sa termoparom i digitalnim multimetrom*

Greška e_{DUT} termometra koji se etalonira (DUT) modeluje se izrazom:

$$E_{DUT}=(T_{m\,DUT}+\delta T_{DUT}) - \\ -\left(T_s(k_{ess}+\delta e_S+ k_{es})+k_{TP}+k_{DriftTP}+k_{Stab}+k_{HomR}+k_{HomA}\right),$$

gde je:

$T_{m\,DUT}$ Rezultat (aritmetička sredina) merenja temperature DUT;

δT_{DUT} Korekcija merenja temperature DUT, zbog konačne rezolucije očitavanja;

T_s Temperatura etaloniranja, kao funkcija elektromotorne sile etalonskog termopara;

k_{ess} Korekcija očitanja elektromotorne sile e_s, zbog rasipanja rezultata merenja elektromotorne sile etalonskog termopara;

δe_S Korekcija očitanja elektromotorne sile e_s, zbog konačne rezolucije očitavanja elektromotorne sile etalonskog termopara;

k_{es} Korekcija merenja elektromotorne sile e_s, zbog netačnosti merenja elektromotorne sile etalonskog termopara. Ocena korekcije se preuzima iz uverenja o etaloniranju merila elektromotorne sile. Nesigurnost korekcije se preuzima iz uverenja o etaloniranju ili se koriste podaci o tačnosti merila elektromotorne sile, datih od strane proizvođača;

k_{TP} Korekcija merenja temperature etaloniranja, zbog netačnosti etalonskog termopara (TP). Nesigurnost korekcije se preuzima iz uverenja o etaloniranju ili se koriste podaci o tačnosti etalonskog termopara, datih od strane proizvođača;

$k_{DriftTP}$ Korekcija merenja temperature etaloniranja, zbog drifta etalonskog termopara;

k_{Stab} Korekcija merenja temperature etaloniranja, zbog nestabilnosti temperature etaloniranja tokom vremena etaloniranja;

k_{HomR} Korekcija merenja temperature etaloniranja, zbog radijalne nehomogenosti temperature u zoni etaloniranja;

k_{HomA} Korekcija merenja temperature etaloniranja, zbog aksijalne nehomogenosti temperature u zoni etaloniranja.

Analiza merne nesigurnosti rezultata etaloniranja DUT (merila temperature sa direktnim očitavanjem), kada se etalon sastoji od termopara i digitalnog multimetra, prikazana je primerima u obliku budžeta merne nesigurnosti.

Primer 2.

Etaloniran je digitalni termometar sa rezolucijom od 1 °C na temperaturi 300 °C.

T_{DUT} je srednja vrednost od pet uzastopnih očitanja DUT. Etalonski merni sistem se sastoji od etalonskog termopara (Termotehna, tip S, granice greške ± 0.5 °C) i digitalnog multimetra (8846 A, opseg 100 mV, rezolucija 10 nV, tačnosti ± (37 ppm od izmerene vrednosti + 35 ppm od mernog opsega)).

T_s je srednja vrednost od pet uzastopnih očitanja etalonskog merila temperature. Sredina je peć za etaloniranje termoparova (nestabilnost temperature etaloniranja tokom vremena iznosi 0.1 °C, radijalna nehomogenost 0.5 °C i aksijalna nehomogenost 1.0 °C). Termometar je etaloniran u Laboratoriji.

Prikaz budžeta nesigurnosti rezultata etaloniranja prikazan je u Tabeli VIII. Kombinovana merna nesigurnost rezultata etaloniranja $u(e_{DUT})$ je 1.3 °C, a proširena merna nesigurnost rezultata etaloniranja $U(e_{DUT})$ za faktor obuhvata k=2 iznosi 2.5 °C.

TABELA VIII

C. *Kalibratori temperature*

Greška e_{DUT} termometra koji se etalonira (DUT) modeluje se izrazom:

$$E_{DUT}=(T_{m\,DUT}+\delta T_{DUT})-\left(T_s+k_{T_s}+k_{Stab}+k_{HomR}+k_{HomA}\right),$$

gde je:

$T_{m\,DUT}$ Rezultat (aritmetička sredina) merenja temperature DUT;

δT_{DUT} Korekcija merenja temperature DUT, zbog konačne rezolucije očitavanja ;

T_s Temperatura etaloniranja (pokazivanje kalibratora temperature);

k_{Ts} Korekcija zadate temperature etaloniranja, zbog netačnosti kalibratora temperature. Nesigurnost korekcije se preuzima iz uverenja o etaloniranju ili se koriste podaci o tačnosti kalibratora, datih od strane proizvođača;

k_{Stab} Korekcija merenja temperature etaloniranja, zbog nestabilnosti temperature etaloniranja tokom vremena etaloniranja;

k_{HomR} Korekcija merenja temperature etaloniranja, zbog radijalne nehomogenosti temperature u zoni etaloniranja;

k_{HomA} Korekcija merenja temperature etaloniranja, zbog aksijalne nehomogenosti temperature u zoni etaloniranja.

Analiza merne nesigurnosti rezultata etaloniranja DUT (merila temperature sa direktnim očitavanjem), kada je etalon kalibrator temperature, prikazana je primerima u obliku budžeta merne nesigurnosti.

Primer 3.

Etaloniran je digitalni termometar sa rezolucijom 0.1 °C na temperaturi – 20 °C. T_{DUT} je srednja vrednost od pet uzastopnih očitanja DUT. Etalonski merni sistem je kalibrator temperature Hart, 9103, granice greške ± 0.25 °C. T_s je temperatura zadata kalibratorom. Nestabilnost temperature etaloniranja tokom vremena iznosi 0.03 °C, radijalna nehomogenost 0.1 °C i aksijalna nehomogenost 0.1 °C. Termometar je etaloniran u Laboratoriji.

Prikaz budžeta nesigurnosti rezultata etaloniranja je prikazan u Tabeli IX. Greška DUT je – 0.20 °C, kombinovana standardna nesigurnost 0.17 °C, a proširena nesigurnost za faktor obuhvata $k = 2$ iznosi 0.35 °C.

V. PROGRAM ZA OBRADU REZULTATA ETALONIRANJA

Pouzdana, jednoznačna i efikasna obrada rezultata etaloniranja svakako podrazumeva neki stepen računarske podrške. Za jednostavnije obrade, Laboratorija koristi odgovarajuće Excel-ove tabele, ali za etaloniranja koja potencijalno obuhvataju veliki broj etalona ili njihovih kombinacija, razvijanje i čuvanje za dalju upotrebu uglednih primeraka Excel-ovih tabela nije racionalno.

Primer 4.

Etaloniran je (izmišljeni) termometar sa direktnim pokazivanjem:

1) u tački – 20 °C

Srednja vrednost merenja DUT iznosi – 20.20 °C, standardna devijacija očitanja DUT 0.02 °C, broj pojedinačnih očitanja DUT je 5 i rezolucija displeja DUT je 0.01 °C. Srednja vrednost očitanja etalona iznosi 23 **Ω**, a standardna devijacija očitanja etalona 0.001 **Ω**. Broj pojedinačnih očitanja etalona je 5.

Kao etaloni su upotrebljeni PRT Tinsley 5187 SA i DMM HP 3458A, a kao sredina alkoholno kupatilo.

2) u tački 0 °C

Srednja vrednost merenja DUT je 0.1 °C, standardna devijacija očitanja DUT 0.02 °C, broj pojedinačnih očitanja DUT je 5, dok rezolucija displeja DUT iznosi 0.01 °C.

Kao etalon upotrebljen je Djuarov sud;

3) u tački 100 °C

Srednja vrednost merenja DUT je 100.1 °C, standardna devijacija očitanja DUT 0.2 °C, broj pojedinačnih očitanja DUT je 5, a rezolucija displeja DUT iznosi 0.1 °C.

Na kalibratoru Hart, 9103 zadata je temperatura od 100 °C;

4) u tački 200 °C

Srednja vrednost merenja DUT je 200.2 °C, standardna devijacija očitanja DUT 0.2 °C, broj pojedinačnih očitanja DUT je 5, a rezolucija displeja DUT iznosi 0.1 °C. Srednja vrednost očitanja etalona je 176.0 **Ω**, standardna devijacija očitanja etalona 0.005 **Ω**, broj pojedinačnih očitanja etalona je 5.

Kao etaloni upotrebljeni su PRT Fluke 884X i DMM Fluke 8846A, a u sredini Hart, 9140;

5) u tački 500 °C

Srednja vrednost merenja DUT je 500.2 °C, standardna devijacija očitanja DUT 0.2 °C, broj pojedinačnih očitanja DUT je 5, dok je rezolucija displeja DUT 0.1 °C. Srednja vrednost očitanja etalona je 4230 µV, standardna devijacija očitanja etalona 0.5 µV, broj pojedinačnih očitanja etalona je 5.

Kao etaloni upotrebljeni su TP Termotehna, S tip i DMM HP 3458A, a u sredini peć za etaloniranje;

6) u tački 1000 °C

Srednja vrednost merenja DUT je 1002 °C, standardna devijacija očitanja DUT 0.3 °C, broj pojedinačnih očitanja DUT je 5, dok je rezolucija displeja DUT 1 °C.

Na kalibratoru Isotech, Pegasus 1200 je zadata temperatura od 1000 °C.

Rezultati etaloniranja su predstavljeni na Sl. 3.

Etaloniranje termometra sa direktnim ocitavanjem

Proizvodjac: XXX
Model: ABC123
Serijski broj: 123A456
Datum etaloniranja: 30.11.2014. god.

Rezultat etaloniranja

Pokazivanje etalona °C	Ocitanje DUT °C	Greska DUT °C	Nesigurnost °C
-20.972	-20.20	0.77	0.035
0.000	0.01	0.01	0.012
100.00	100.1	0.1	0.43
200.25	200.2	-0.1	0.53
499.9	500.2	0.3	1.7
1000.0	1002.	2.	2.7

Sl. 3. Izgled priloga uz Uverenja o etaloniranju sa rezultatima etaloniranja

ABSTRACT

The paper presents an example of the procedure for the calibration of direct reading thermometers in the Laboratory. It demonstrates the optimal ways of measuring. In addition, it offers a description of the preparation for measuring and lists the measuring equipment that has been used. It also features a description of the measuring procedures that need to be applied and it shows the processing of the measurement results. It provides the examples illustrating the application of this instruction manual. All the terms and definitions meet the requirements of SRPS ISO/IEC 9000:2001, SRPS ISO/IEC 17025:2017 and follow International Vocabulary of Basic and General Terms in Metrology.

A Contribution to the Calibration of Direct Reading Thermometers in the Laboratory

***Apstrakt* — U ovom radu je dat postupak etaloniranja čitača dozimetara u Laboratoriji za metrologiju Fakulteta tehničkih nauka u Novom Sadu. Prikazane su najbolje mogućnosti merenja, opisana je priprema za merenje i navedena je merna oprema koja se koristi. Opisani su postupci merenja koje treba sprovesti, prikazana je obrada dobijenih rezultata i određena je forma procene merne nesigurnosti. Dat je primer etaloniranja čitača dozimetara. Svi termini i definicije su u skladu sa JUS ISO/IEC 9000:2001, SRPS ISO/IEC 17025:2017 i Međunarodnim rečnikom osnovnih i opštih termina u metrologiji.**

***Ključne reči* —** merna oprema; etaloniranje; metrologija; čitač dozimetara; merna nesigurnost.

I. Uvod

U Tabeli I su prikazane merne mogućnosti etaloniranja čitača dozimetara raspoloživom opremom Laboratorije za metrologiju Fakulteta tehničkih nauka u Novom Sadu (u daljem tekstu samo Laboratorija).

TABELA I
NAJBOLJE MOGUĆNOSTI MERENJA

Veličina	Predmet etaloniranja	Opseg	Merna nesigurnost
Jačina struje	Elektrometri	1 pA do 100 mA	≤ 0.05%

Posebni termini korišćeni u ovom uputstvu imaju sledeća značenja:

Čitač dozimetara – uređaj, deo dozimetra, koji meri struju odnosno naelektrisanje iz detektora i konvertuje u oblik pogodan za prikaz veličine kao što je apsorbovana doza, ekvivalentna doza, efektivna doza, kerma i odgovarajuće jačine doza ili kerme;

Marina Bulat – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: marina.bulat@uns.ac.rs). Nemanja Gazivoda – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: nemanjagazivoda@uns.ac.rs). Ivan Gutai – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: gutai@uns.ac.rs). Bojan Vujičić– Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: bojanvuj@uns.ac.rs). Dragan Pejić – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: pejicdra@uns.ac.rs). Marjan Urekar – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: urekarm@uns.ac.rs).

Nelinearnost - odstupanje odziva elektrometra od linearnosti. Procentualno odstupanje od linearnosti se izračunava iz relacije

$$100\cdot\left(\frac{m\cdot Q}{M\cdot q} - 1\right),$$

gde M i m predstavljaju očitavanja na elektrometru za prvu i drugu izabranu referentnu vrednost fizičke veličine, respektivno, a Q i q ulazne signale potrebne da bi proizvele referentnu vrednost za prvu i drugu izabranu vrednost fizičke veličine, respektivno. Za merenje naelektrisanja koristi se DOSE režim rada, a za merenje struje DOSE RATE;
Rezolucija prikaza - najmanja promena očitavanja na skali koja se može uočiti bez dodatne interpolacije. Za analogni prikaz odnosno displej je to najmanja frakcija intervala skale koji se može uočiti pri određenim uslovima. Kod digitalnih prikaza to je najmanji značajni inkrement očitavanja;

Odziv - odnos vrednosti prikazane na čitaču dozimetra i ulazne struje dobijene iz strujnog izvora;
Drift nule - kontinualna promena oko nulte vrednosti očitavanja na skali pri uslovima kada na elektrometru nema signala;

Šift nule - iznenadna promena u nultom očitavanju na skali elektrometra kada se režim merenja prebaci sa „nula" na „merenje" u uslovima kada nema mernog signala.

II. Opis aktivnosti

A. *Priprema za rad*

Priprema za etaloniranje podrazumeva vizuelni pregled objekta etaloniranja, konstataciju da je objekt pripremljen za etaloniranje i proveru referentnih uslova etaloniranja.

B. *Vizuelni pregled*

Vizuelnim pregledom se utvrđuje opšte stanje objekta etaloniranja i konstatuju se eventualna oštećenja. Utvrđuje se i postojanje dokumentacije o objektu etaloniranja, relevantne za etaloniranje. Čitač dozimetara (koji može biti odvojen od detektora ili njegov sastavni deo) koji se šalje na pregled mora imati stabilan displej i napunjenu bateriju, ukoliko postoji.

C. *Priprema za etaloniranje*

Potrebno je da objekt etaloniranja bude u Laboratoriji dvanaest sati pre početka etaloniranja, da bi se njegova temperatura izjednačila sa temperaturom okoline. Pre etaloniranja elektrometar treba da bude uključen najmanje dva sata.

D. *Provera referentnih uslova etaloniranja*

Referentni uslovi za merenje u Laboratoriji su:

- Temperatura okoline: (23 ± 2) °C;
- Relativna vlažnost vazduha: (45 ± 15)%.

Referentni uslovi u Laboratoriji se održavaju stalno, a provera podrazumeva ispunjenje navedenih zahteva neposredno pre merenja.

III. MERNA OPREMA

Oprema koja je neophodna za etaloniranje čitača dozimetara je navedena u Tabeli II.

TABELA II
SPISAK MERNE OPREME ZA ETALONIRANJE ČITAČA DOZIMETARA

Oznaka	Naziv	Tip
IJS	Izvor jednosmerne struje	Keithley 6220
	Etalonski otpornici	
DMM	Digitalni multimetar	HP 3458A

IV. POSTUPAK MERENJA

Etaloniranje čitača dozimetara vrši se metodom direktnog merenja. Očitavanja na čitaču su direktno srazmerna intenzitetu jačine struje koja se iz strujnog izvora primenjuje na njegove ulazne krajeve bilo direktno bilo preko etalonskog otpornika prema izrazu:

$$I=\frac{U}{R}.$$

Čitači se etaloniraju u najmanje pet tačaka koje pokrivaju najmanje 80% njihovog opsega.

Etaloniranje za merenje struje se obavlja korišćenjem strujnog izvora visoke impedanse ili merenjam pada napona na etalonskom otporniku kroz koji je propuštena poznata vrednost struje. Merni opseg struje zavisi od tipa detektora koji se koristi i može biti reda nA (1 nA do 100 nA) i reda pA (5 pA do 500 pA).

Uslovi zadavanja struje na strujnom izvoru pri etaloniranju dati su u Tabeli III.

TABELA III
USLOVI ZADAVANJA STRUJE STRUJNOG IZVORA PRI ETALONIRANJU

Opseg	Tačnost (23 °C)	Rezolucija
1 pA	0.2% + 1 pA	100 fA
10 pA	0.2% + 1 pA	100 fA
100 pA	0.2% + 1 pA	100 fA
500 pA	0.4% + 2 pA	100 fA
1 nA	0.4% + 2 pA	100 fA
2 nA	0.4% + 2 pA	100 fA
20 nA	0.3% + 10 pA	1 pA
200 nA	0.3% +100 pA	10 pA

Koeficijent etaloniranja ili kalibracioni faktor se izračunava za svaki opseg posebno kao srednja vrednost odnosa pokazivanja na čitaču i zadate struje. Koeficijent etaloniranja se izražava u jedinicama Sv/A, Gy/A, A/A ili u umnošcima pomenutih mernih jedinica. Koeficijent etaloniranja (kalibracioni faktor) se određuje za svaki merni opseg. Potrebno je proveriti da li displej pokazuje 0.000 ± 1 count. Ukoliko to nije slučaj, neophodno je podesiti nulu.

Kod merila koja imaju više opsega za svaki se određuje faktor kalibracije (koeficijent etaloniranja) koji se izražava kroz faktore promene opsega. Ti faktori su procenjeni u odnosu na opseg koji je izabran kao referentan i za koji je faktor promene opsega jednak jedinici. Kalibracioni faktori (koeficijenti etaloniranja) se međusobno ne smeju razlikovati za više od 0.5%.

U zavisnosti od detektora koji se koristi, čitači imaju različite linearne odzive. Provera linearnosti se sastoji od određivanja koeficijenta etaloniranja u odnosu na struju za različite opsege. Linearnost za svaku opseg se izražava kroz korekcioni faktor za nelinearnost, procenjen za svaki niz očitavanja u odnosu na očitavanje na referentnoj skali. Po definiciji, korekcija na nelinearnost je jednaka jedinici na referentnoj skali.

Curenje čitača se određuje posle primene spoljašnjeg izvora struje (koje simulira uslove ozračivanja detektora) i meri se pet minuta. Struja curenja ne sme biti veća od vrednosti koje je specificirao proizvođač, a ukoliko nije specificirano ne sme biti veća od 0.1 pA.

V. ETALONIRANJE ČITAČA DOZIMETARA

Vrednosti dobijene pri etaloniranju moraju biti određene sa relativnom standardnom mernom nesigurnošću i u granicama datim u Tabeli IV.

TABELA IV
GRANICE VARIJACIJE I RELATIVNA STANDARDNA MERNA NESIGURNOST RELEVANTNIH PARAMETARA

Karakteristika	Granice varijacije	Relativna standardna merna nesigurnost
Rezolucija	± 0.02%	± 0.01%
Curenje	± 0.1 pA	± 0.40%
Drift nule	± 1 count	± 0.10%
Šift nule	± 5 fA	± 0.60%
Nelinearnost	± 0.05%	± 0.01%
Promena opsega	± 0.5%	± 0.01%
Ulazna struja	± 0.2%	± 0.10%

Model izračunavanja greške etaloniranog čitača E_X:

$$E_X=(I_X + \delta I_X) - I_e,$$

gde je :

I_X – vrednost struje očitane čitačem koji se etalonira;

δI_X – greška očitavanja na čitaču koji se etalonira nastala zbog konačne rezolucije očitavanja;

I_e – vrednost struje zadate strujnim izvorom.

Koeficijenti osetljivosti su:

$$C_{\delta I_X}=\frac{\partial_{E_X}}{\partial \delta I_X}=1,\ C_{I_e}=\frac{\partial_{E_X}}{\partial I_e}=-1.$$

Merna nesigurnost određivanja greške etaloniranog čitača je:

$$u_{E_X}=\sqrt{\left(C_{\delta I_X}\cdot u_{\delta I_X}\right)^2+\left(C_{I_e}\cdot u_{I_e}\right)^2}$$

U Tabeli V je dat prikaz budžeta mernih nesigurnosti rezultata etaloniranja čitača.

TABELA V
PRIKAZ BUDŽETA MERNIH NESIGURNOSTI REZULTATA ETALONIRANJA ČITAČA

Veličina	Simbol	Merna nesigurnost	Tip merne nesigurnosti	Raspodela verovatnoće	Osetljivost c_i	Doprinos mernoj nesigurnosti
Vrednost struje očitane čitačem koji se etalonira	I_x					
Greška očitavanja, zbog konačne rezolucije očitavanja	δI_x	$\frac{I_{xr}}{2\sqrt{3}}$ Rezolucija (proizvodjač)	B	Pravougaona	1	$\frac{I_{xr}}{2\sqrt{3}}$
Vrednost struje zadate strujnim izvorom	I_e	Prema Tabeli III	B		-1	Prema Tabeli III
Greška čitača	E_x					

VI. PRIMER PROCENE MERNE NESIGURNOSTI

Merna nesigurnost tipa A, u_A, se procenjuje iz standardne devijacije srednje vrednosti ponovljenih merenja. Kombinovana merna nesigurnost je kvadratni koren zbira kvadrata merne nesigurnosti tipa A i B. Proširena merna nesigurnost je dobijena množenjem kombinovane merne nesigurnosti faktora obuhvata $k = 2$ što predstavlja interval u kome je nivo poverenja 95%.

A. Standardna merna nesigurnost tipa A

Merenje fizičke veličine X se ponovi N puta. Najbolja procenjena vrednost je aritmetička sredina svih rezultata merenja x_i:

$$\bar{x}=\frac{1}{N}\cdot\sum_{i=1}^{N}x_i$$

Za izražavanje merne nesigurnosti pojedinačnog rezultata x_i koristi se standardna devijacija:

$$\sigma_x=\sqrt{\frac{1}{N}\cdot\sum_{i=1}^{N}(x_i-\bar{x})^2}.$$

Standardna devijacija srednje vrednosti se koristi za izražavanje merne nesigurnosti najbolje procenjene vrednosti:

$$\sigma_{\bar{x}}=\frac{1}{\sqrt{N}}\cdot\sigma_x.$$

Standardna merna nesigurnost tipa A definisana je kao standardna devijacija srednje vrednosti:

$$u_A=\sigma_{x.}$$

B. Standardna merna nesigurnost tipa B

Procena merne nesigurnosti tipa B, u_B, procenjuje se iz faktora koji utiču na proces merenja, na osnovu korekcionih faktora i podataka iz literature (fizičke konstante i njihove merne nesigurnosti) kao na osnovu odabrane gustine raspodele verovatnoće.

Primer procene merne nesigurnosti tipa B

Pretpostavke:

- meri se struja I=100 pA;
- postoji donja i gornja granična vrednost za pravougaonu raspodelu $(I-\Delta,\ I+\Delta)$;
- postoji 100% verovatnoća da se tačna vrednost nađe u tom intervalu pošto je odabrana pravougaona raspodela.

Korak 1. Projektovati gustinu verovatnoće $p(x)$ za raspodelu vrednosti jačine struje:

$$p(x)=\begin{cases}C, & za\ I-\Delta\le x\le I+\Delta\\ 0\ , & u\ svim\ drugim\ slučajevima.\end{cases}$$

Vrednost integrala u granicama $(I-\Delta,\ I+\Delta)$ mora da bude jednak jedinici, stoga imamo da je:

$$\int p(x)dx=\begin{cases}C\cdot 2\Delta=1, & za\ I-\Delta\le x\le I+\Delta\\ 0, & u\ svim\ drugim\ slučajevima.\end{cases}$$

Za interval $I-\Delta\le x\le I+\Delta$ imamo da je

$$p(x)=\frac{1}{2\Delta}.$$

Korak 2. Izračunati najbolje procenjenu vrednost fizičke veličine (srednju vrednost) i varijansu v:

$$\bar{x}=\int_{-\infty}^{+\infty}x\cdot p(x)dx=\frac{1}{2\cdot\Delta}\cdot\int_{I-\Delta}^{I+\Delta}xdx=I$$

$$v=\int_{-\infty}^{+\infty}(x-\bar{x})^2\cdot p(x)dx=\frac{1}{2\cdot\Delta}\cdot\int_{I-\Delta}^{I+\Delta}(x-I)^2dx=\frac{1}{3}\cdot\Delta^2$$

$$u_B=\sqrt{v}=\frac{\Delta}{\sqrt{3}}.$$

U Tabeli VI je dat prikaz budžeta mernih nesigurnosti rezultata etaloniranja čitača (za zadatu struju 100 pA).

TABELA VI
PRIKAZ BUDŽETA MERNIH NESIGURNOSTI REZULTATA ETALONIRANJA ČITAČA(ZA ZADATU STRUJU 100 PA)

Veličina	Simbol	Merna nesigurnost	Tip merne nesigurnosti	Raspodela verovatnoće	Osetljivost c_i	Doprinos mernoj nesigurnosti
Vrednost struje očitane čitačem koji se etalonira	102 pA	0.612 pA				0.612 pA
Greška očitavanja, zbog konačne rezolucije očitavanja	100 fA	28.9 fA	B	Pravougaona	1	28.9 fA
Vrednost struje zadate strujnim izvorom	100 pA	0.05 pA	B		-1	0.05 pA
Greška čitača	E_x					0.614 pA

***Apstrakt*—Na osnovu metode poređenja u radu je opisan postupak etaloniranja pokaznih naprava termometara sa termoparovima unutar i van metrološke laboratorije. Obrađene su i prikazane najbolje mogućnosti merenja, postupak pripreme za etaloniranje, dokumentovana je merna oprema koja se koristi kao i postupci merenja i prikazani su specifični rezultati etaloniranja propraćeni odgovarajućim mernim nesigurnostima**

***Ključne reči*—termometar; termopar; kalibrator; multimetar; etaloniranje; merna nesigurnost; budžet merne nesigurnosti; metrologija.**

I. UVOD

Laboratorija za metrologiju Fakulteta tehničkih nauka u Novom Sadu vrši etaloniranje pokaznih naprava termometara sa termoparovima, što je opisano u ovom radu. Kao krajnji proizvod etaloniranja Laboratorija izdaje dokument Uverenje o etaloniranju koje se izdaje klijentu saglasno dokumentovanom sistemu kvaliteta. Etaloniranje pokaznih naprava termometara sa termoparovima kao i sam postupak, određen je radnim uputstvom izrađenim od strane tima saradnika Laboratorije za metrologiju, na osnovu EURAMET-ovih saveta i uputstava iz [2]. U radnom uputstvu, svi termini i definicije su u skladu sa SRPS ISO/IEC 9000:2015, SRPS ISO/IEC 17025:2017 i Međunarodnim rečnikom osnovnih i opštih termina u metrologiji.

Termometri sa termoparovima rade na principu merenja termoelektričnog napona na krajevima ugrađenog termopara, koji zavisi od temperaturnog gradijenta – Seebeck efekat, koji se može pozvati na Peltier i Thomson efekat. Etaloniranje pokazne naprave vrši se metodom poređenja. Na pokaznu napravu (DUT) se, umesto termopara, priključuje izvor etalonske elektromotorne sile (ems, EMS) za simuliranje termopara. Očitanja na pokaznoj napravi termometra porede se sa izračunatim vrednostima temperature definisanim standardom ili od strane proizvođača pokazne naprave, koje odgovaraju zadatim vrednostima elektromotornih sila.

II. MERNE MOGUĆNOSTI I MERNA OPREMA

Merne mogućnosti u vidu mernih nesigurnosti etaloniranja pokaznih naprava termometara sa termoparovima, raspoloživom opremom Laboratorije prikazane su u tabeli ispod.

TABELA I
MERNE MOGUĆNOSTI

Veličina	Predmet etaloniranja	Opseg	Merna nesigurnost*
Temperatura	Pokazna naprava termometara sa termoparom (unutar laboratorije)	od -200 °C do +1800 °C	0,3 °C
	Pokazna naprava termometara sa termoparom (van laboratorije)	od -200 °C do +1300 °C	1,2 °C

*Merna nesigurnost je proširena merna nesigurnost, gde je standardna merna nesigurnost pomnožena faktorom obuhvata k=2, što za slučaj normalne raspodele greške odgovara verovatnoći od približno 95 %.

Merna oprema

Referentni etaloni, radni etaloni i pomoćna oprema Laboratorije koja se koristi za etaloniranje pokaznih naprava prikazani su u Tabeli II.

TABELA II
ETALONI I POMOĆNA OPREMA

Referentni etaloni	
Naziv	Tip

Termometar/higrometar	445815

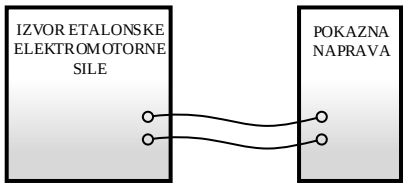
III. ETALONIRANJE UNUTAR LABORATORIJE

Vizuelni pregled objekta etaloniranja, konstatacija da je objekt pripremljen za etaloniranje i provera referentnih uslova etaloniranja unutar Laboratorije se podrazumevaju pre samog etaloniranja. Utvrđuje se opšte stanje objekta etaloniranja i konstatuju se eventualna oštećenja. Utvrđuje se, takođe, i postojanje dokumentacije o objektu etaloniranja, relevantne za etaloniranje. Objekt etaloniranja mora da bude u Laboratoriji najmanje 12 sati pre početka etaloniranja, da bi se njegova temperatura izjednačila sa temperaturom okoline. Uslovi za merenje u Laboratoriji su:

Temperatura okoline: (23 ± 2) °C;
Relativna vlažnost vazduha: (45 ± 15) %.

Ovi uslovi se održavaju stalno, i podrazumeva se ispunjenje navedenih referentnih uslova neposredno pre merenja.

Etaloniranje bez kompenzacije hladnog spoja



Sl. 1. Blok šema etaloniranja pokazne naprave termometra sa termoparom

Model izračunavanja greške E_X pokazne naprave je:

$$E_X = (T_X + \delta T_X) - T(V_S + \delta V_S) \tag{1}$$

gde je:

T_X Pokazivanje pokazne naprave;
δT_X Korekcija očitanja pokazne naprave, zbog konačne rezolucije očitavanja;
$T(V)$ Temperatura koja odgovara elektromotornoj sili V, definisana standardom ili od strane proizvođača pokazne naprave;
V_S Etalonska ems kojom se simulira termopar;
δV_S Korekcija zbog netačnosti merenja etalonske ems;

Vrednost etalonske ems V_S meri se digitalnim multimetrom sa granicama greške $\pm G_{V_S}$ određene specifikacijom proizvođača. Za gustinu raspodele verovatnoće greške merenja digitalnim multimetrom kao i gustinu raspodele greške očitavanja pokazne naprave se smatra da imaju ravnomernu raspodelu.

Standardna merna nesigurnost očitanja pokazne naprave zbog konačne rezolucije očitavanja određena je izrazom (2), gde je LSD (*Least Significiant Digit*) rezolucija displeja pokazne naprave:

$$u(\delta T_X) = \frac{LSD}{2\sqrt{3}} \tag{2}$$

Standardna merna nesigurnost koja potiče od greške multimetra određena je izrazom:

$$u(\delta V_S) = \frac{G_{V_S}}{\sqrt{3}} \tag{3}$$

Koeficijenti osetljivosti su:

$$c_1 = \frac{\partial E_X}{\partial \delta T_X} = 1 \tag{4}$$

$$c_2 = \frac{\partial E_X}{\partial \delta V_S} = -\frac{\partial T(V_S + \delta V_S)}{\partial \delta V_S} \tag{5}$$

Kombinovana standardna merna nesigurnost određivanja greške etaloniranja pokazne naprave:

$$u(E_X) = \sqrt{[c_1 \cdot u(\delta T_X)]^2 + [c_2 \cdot u(\delta V_S)]^2} \tag{6}$$

Proširena merna nesigurnost U definisana je sa:

$$U = k \cdot u(E_X) \tag{7}$$

Etalonirana je pokazna naprava, za opseg temperatura od 0 °C do +1200 °C, sa rezolucijom od LSD=0,1 °C, predviđena da se na nju priključi termopar tipa K. Vrednost etalonske elektromotorne sile kojom se simulira termopar izmerena je digitalnim multimetrom Hewlett Packard 3458A.

TABELA III
EVIDENCIJA REZULTATA ETALONIRANJA

Očitanje pokazne naprave	Etalonska ems	Etalonska temperatura*	Greška pokazne naprave	Nesigurnost**	Faktor obuhvata
T_X (°C)	V_S (mV)	$T(V_S)$ (°C)	E_X (°C)	U (°C)	k
0,0	0,000	0,00	0,0	0,058	2
199,0	8,100	199,02	0,0	0,059	2

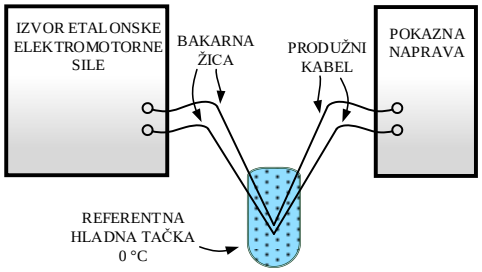
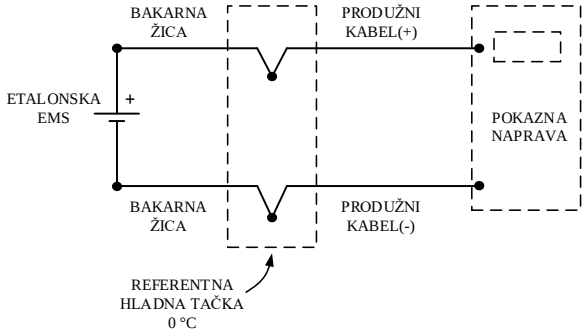
Etaloniranje sa kompenzacijom hladnog spoja



Sl. 2. Blok šema etaloniranja pokazne naprave termometra sa termoparom sa kompenzacijom hladnog spoja

Blok šema sa Sl. 2 pokazuje način povezivanja kod etaloniranja sa kompenzacijom hladnog spoja, prema [2]. Izvor etalonske ems generiše napon kojim se simulira termopar, i taj napon se preko bakarnih provodnika vodi do referentne hladne tačke (referentne temperature). Na referentnoj temperaturi bakarni provodnici su kratkospojeni sa produžnim kablovima koji je povezuju sa DUT.

Hemijski sastav produžnih kablova zavisi od tipa termopara koji se simulira, odnosno od DUT. Električna šema za etaloniranje sa kompenzacijom hladnog spoja nalazi se na Sl. 3. Ovo kolo je jedno od osnovnih kola, kako pri etaloniranju termometara, tako i pri merenju temperature termoparovima. Detaljnije objašnjenje principa funkcionisanja ovog kola može se naći u [3], [4] i [5].



Sl. 3. Električna šema etaloniranja pokazne naprave termometra sa termoparom sa kompenzacijom hladnog spoja

Model izračunavanja greške E_X pokazne naprave je:

$$E_X = (T_X + \delta T_X) - T(V_S + \delta V_S + \delta V_{S-par} + \delta V_{S-ext} + \delta V_{S-extDrift}) + \frac{S_0}{S_X}\delta T_0 \tag{8}$$

gde je:

T_X Pokazivanje pokazne naprave;
δT_X Korekcija očitanja pokazne naprave, zbog konačne rezolucije očitavanja;
$T(V)$ Temperatura koja odgovara ems V , definisana standardom ili od strane proizvođača pokazne naprave;
V_S Etalonska ems kojom se simulira termopar;
δV_S Korekcija zbog netačnosti merenja V_S;
$\delta V_{S\text{-}par}$ Korekcija ems, zbog prisustva parazitnih efekata u mernom kolu (termoelektrični, CM, strano magnetno polje);
$\delta V_{S\text{-}ext}$ Korekcija ems, zbog netačnosti karakteristika produžnih provodnika;
$\delta V_{S\text{-}extDrift}$ Korekcija ems, zbog drifta karakteristika produžnih produžnih;
δT_0 Korekcija temperature etaloniranja, zbog netačnosti temperature hladnog kraja;
S_0 , S_X Zebekovi koeficijenti, za temperature od 0 °C i temperaturu etaloniranja T_X ;

Standardne merne nesigurnosti usled:

1) Ponavljanja merenja (tip A)

$$u(T_X) = \sqrt{\frac{1}{n(n-1)}\sum_{i=1}^{n}(T_i - T_X)^2} \tag{9}$$

gde je:

- n Ukupan broj očitanja sa DUT;
- T_i Vrednost rezultata i-tog merenja očitana na DUT
- T_X Aritmetička sredina pokazivanja DUT

2) Konačne rezolucije očitanja sa DUT (tip B)

$$u(\delta T_X) = \frac{LSD}{2\sqrt{3}} \tag{10}$$

3) Netačnosti merenje etalonske ems (tip B)

$$u(\delta V_S) = \frac{G_{Vs}}{\sqrt{3}} \tag{11}$$

Sve ostale merne nesigurnosti, su merne nesigurnosti tipa B, i određuju se na osnovu specifikacija proizvođača ili rezultata zadnjeg etaloniranja. Koeficijenti osetljivoti su:

$$c_1 = \frac{\partial E_X}{\partial T_X} = 1 \tag{12}$$

$$c_2 = \frac{\partial E_X}{\partial \delta T_X} = 1 \tag{13}$$

$$c_3 = -\frac{\partial T(V_S + \delta V_S + \delta V_{S-par} + \delta V_{S-ext} + \delta V_{S-extDrift})}{\partial \delta V_S} \tag{14}$$

$$c_4 = -\frac{\partial T(V_S + \delta V_S + \delta V_{S-par} + \delta V_{S-ext} + \delta V_{S-extDrift})}{\partial \delta V_{S-par}} \tag{15}$$

$$c_5 = -\frac{\partial T(V_S + \delta V_S + \delta V_{S-par} + \delta V_{S-ext} + \delta V_{S-extDrift})}{\partial \delta V_{S-ext}} \tag{16}$$

$$c_6 = -\frac{\partial T(V_S + \delta V_S + \delta V_{S-par} + \delta V_{S-ext} + \delta V_{S-extDrift})}{\partial \delta V_{S-extDrift}} \tag{17}$$

$$c_7 = \frac{\partial E_X}{\partial T_0} = \frac{S_0}{S_X} \tag{18}$$

Kombinovana merna nesigurnost određivanja greške etaloniranja DUT:

$$u(E_X) = \sqrt{[c_1 u(T_X)]^2 + [c_2 u(\delta T_X)]^2 + [c_3 u(\delta V_S)]^2 + [c_4 u(\delta V_{S-par})]^2 + [c_5 u(\delta V_{S-ext})]^2 + [c_6 u(\delta V_{S-extDrift})]^2 + [c_7 u(\delta T_0)]^2} \tag{19}$$

TABELA V
BUDŽET MERNE NESIGURNOSTI ETALONIRANJA UNUTAR LABORATORIJE ZA TEMPERATURU OD +998,96 °C

Naziv veličine	Simbol	Ocena	Parcijalna nesigurnost	Tip nesigurnosti	Raspodela	Koeficijent osetljivosti	Doprinos nesigurnosti

Korekcija temeprature etaloniranja, zbog netačnosti temperature hladnog kraja	δT_0	0 mV	11,5 µV	B	ravnomerna	1,01	0,012 °C
Greška pokazne naprave	E_X	3,0 °C				Kombinovana merna nesigurnost	0,41 °C
						Proširena merna nesigurnost (k=2)	0,83 °C

Etalonirana je pokazna naprava, za opseg temperatura do +1200 °C, sa rezolucijom od LSD=1 °C , predviđena da se na nju priključi termopar tipa K. Etaloniranje je sprovedeno prema šemi na Slici 2. Tačka etaloniranja je +998,06 °C. Etalonski sistem se sastoji od kalibratora elektromotorne sile, (Time Electronics 5025), Djuartovog suda za realizaciju temperature od 0 °C i produžnih kablova za termopar tipa K.

IV. ETALONIRANJE VAN LABORATORIJE

Provera metroloških karakteristika etalonskog sistema pre odlaska na mesto etaloniranja, vizuelni pregled objekta etaloniranja, konstatacija da je objekt pripremljen za etaloniranje i provera referentnih uslova etaloniranja se podrazumevaju pre samog etaloniranja. Pre i nakon prenosa etalonskog sistema vrši se provera osnovnih metroloških karakteristika etalona, kako bi se smanjili rizici tokom prenošenja opreme do i od mesta etaloniranja. Oprema za etaloniranje do i od mesta etaloniranja bi po pravilu trebalo da se prenosi putničkim automobilom.

Etalonska oprema i objekt etaloniranja bi trebalo da budu u prostoru namenjenom za etaloniranje najmanje 1 sat pre početka etaloniranja, kako bi se njihova temperatura približno izjednačila sa temperaturom okoline. Prostor u kome treba da se obavi etaloniranje mora da bude suv, čist, bez prašine i drugih agensa koji mogu da deluju na mernu opremu, i da se u njemu ne odvijaju druge aktivnosti koje mogu loše da utiču na merenja. Utvrđuje se opšte stanje objekta etaloniranja i konstatuju se eventualna oštećenja, kao i postojanje dokumentacije o objektu etaloniranja, relevantne za etaloniranje.

Uslovi za merenje van Laboratorije su:

Temperatura okoline: 10 °C do 30 °C;
Relativna vlažnost vazduha: 40 % do 80 %.

Neposredno pre merenja podrazumeva se ispunjenje navedenih referentnih uslova.

Blok šema etaloniranja pokazne naprave van Laboratorije je ista kao šema na Slici 1.

Model izračunavanja greške E_X pokazne naprave je:

$$E_X = (T_X + \delta T_X) - T(V_S + \delta V_S + \delta V_{S-temp}) \quad (20)$$

gde je:

T_X Pokazivanje pokazne naprave;
δT_X Korekcija očitanja pokazne naprave, zbog konačne rezolucije očitavanja;
$T(V)$ Temperatura koja odgovara ems V , definisana standardom ili od strane proizvođača pokazne naprave;
V_S Etalonska ems kojom se simulira termopar;
δV_S Korekcija zbog netačnosti merenja etalonske ems;
$\delta V_{S\text{-temp}}$ Korekcija zbog netačnosti merenja etalonske ems ako temperatura okoline izlazi van referentnog opsega temperatura etalonskog merila ems;

Vrednost etalonske ems V_S meri se multimetrom sa granicama greške G_{Vs} određene specifikacijom proizvođača. U slučaju da ambijentalna temperatura izađe van referentnog temperaturnog opsega multimetra, granice greške merenja napona se povećavaju zbog uticaja dodatne greške $G_{Vs\text{-temp}}$, koja je posledica ambijentalne temperature. Za gustinu raspodele verovatnoće greške merenja digitalnim multimetrom kao i gustinu raspodele greške očitavanja pokazne naprave se smatra da imaju ravnomernu raspodelu.

Standardna merna nesigurnost očitanja pokazne naprave zbog konačne rezolucije očitavanja određena je formulom:

$$u(\delta T_X) = \frac{LSD}{2\sqrt{3}} \quad (21)$$

Standardna merna nesigurnost koja potiče od digitalnog multimetra određena je izrazom:

$$u(\delta V_S) = \frac{G_{Vs}}{\sqrt{3}} \quad (22)$$

Standardna merna nesigurnost koja potiče od dodatne greške multimetra usled ambijentalne temperature je:

$$u(\delta V_{S-temp}) = \frac{G_{Vs-temp}}{\sqrt{3}} \quad (23)$$

Koeficijenti osetljivosti su:

$$c_1 = \frac{\partial E_X}{\partial \delta T_X} = 1 \quad (24)$$

$$c_2 = \frac{\partial E_X}{\partial \delta V_S} = -\frac{\partial T(V_S + \delta V_S + \delta R V_{S-temp})}{\delta V_S} \quad (25)$$

$$c_3 = \frac{\partial E_X}{\partial \delta V_{S-temp}} = -\frac{\partial T(V_S + \delta V_S + \delta V_{S-temp})}{\delta V_{S-temp}} \quad (26)$$

Merna nesigurnost određivanja greške etaloniranja pokazne naprave predviđene za rad sa termoparovima:

$$u(E_X) = \sqrt{[c_1 \cdot u(\delta T_X)]^2 + [c_2 \cdot u(\delta V_S)]^2 + [c_3 \cdot u(\delta V_{S-temp})]^2} \quad (27)$$

Etalonirana je pokazna naprava, za opseg temperatura od 0 °C do +1200 °C, sa rezolucijom od LSD=0,1 °C, predviđena da se na nju priključi termopar tipa K. Vrednost etalonske elektromotorne sile V_S kojim se simulira termopar izmerena je digitalnim multimetrom Fluke 8846A. Temperatura etaloniranja je +499,5 °C.

TABELA VI
BUDŽET MERNE NESIGURNOSTI ETALONIRANJA VAN LABORATORIJE ZA TEMPERATURU OD +498,96 °C

			Proširena merna nesigurnost (k=2)				0,093 °C

V. ZAKLJUČAK

Etaloniranje pokaznih naprava termometara sa termoparovima saglasno je dokumentovanom sistemu kvaliteta Laboratorije za metrologiju. Opisana metoda etaloniranja je jedna od metoda koje se koriste u Laboratoriji za etaloniranje pokaznih naprava termometara i koja se poziva naa savete i uputstva iz uputstva [2]. Pored raznih softverskih i hardverskih kompenzacija hladnog kraja koje mogu da se implementiraju, merne nesigurnosti i ovako opisanih metoda ispunjavaju većinu zahteva klijenata Laboratorije, kada su u pitanju pokazne naprave termometara, kako u slučajevima etaloniranja sa tako i u slučajevima bez kompenzacije hladnog kraja.

ZAHVALNICA

Ovaj rad je delom podržan od strane projekta ELEMEND (šifra projekta: 585681-EEP-1-2017-EL-EPPKA2-CBHE-JP).

ABSTRACT

Based on the comparison method, in this paper, the procedure of calibration of temperature indicators with thermocouples is described for conditions inside and outside the metrology laboratory. The best measurement possibilities and process of preparation for calibration is processed, as well as the used equipment. Specific calibration results were presented, accompanied by measurement uncertainties.

The Contribution to The Calibration of Temperature Indicators With Thermocouples

Web-bazirani merni sistemi – primer edukativnog front-enda

Ivan Gutai, *Member, IEEE,* Đorđe Novaković, *Member, IEEE,* Platon Sovilj, *Member, IEEE,* Dragan Pejić, *Member, IEEE,* Marina Bulat, *Member, IEEE,* Nemanja Gazivoda, *Member, IEEE*

***Apstrakt* — U ovom radu je prikazan primer front-end modula koji omogućava prikaz rezultata merenja sa sedam različitih senzora uz prilagodljiv dizajn koji omogućava preglednost i sa računara, ali i sa prenosnih uređaja. Svaki senzor ima zaseban panel, na visokim rezolucijama se prikazuju dva u istom redu, dok se na prenosnim uređajima slažu jedan ispod drugog. Svaki panel prikazuje listu svih rezultata merenja i vreme kada su merenja izvršena, a istovremeno se i radi lakšeg nadzora prikazuje i grafik sa svim vrednostima. Svaki od osnovnih primera koji sadrže programski kod u JavaScript-u, koji se daju kao dodatak uz ovaj rad, pored edukativnog karaktera su predviđeni i da se savladaju za manje od 15 minuta, što čini celu ovu zamisao kompatibilnom sa osnovnim principima tzv. Microlearning-a.**

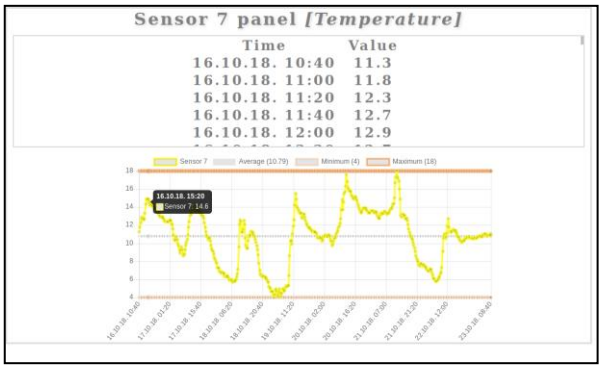
***Ključne reči*—Web-bazirani merni sistemi; Microlearning; JavaScript; HTML 5; CSS 3; Chart.js; Metrologija**

I. Uvod

Metrološki lanac, razvojem informaciono-komunikacionih tehnologija i evolucijom merne instrumentacije od analognih mernih instrumenta do složenih merno-informacionih sistema, vremenom je usložnjen. Bitni segmenti tog lanca su različiti moduli merno-informacionih sistema, uključujući i front-end module. Ovaj rad prikazuje jedan primer front-end modula web-baziranog mernog sistema, projektovanog za edukativne i razvojne svrhe.

Svedoci smo naglog uspona softverske industrije u poslednjih nekoliko decenija, čime softver postaje gradivni element većine savremenih uređaja. Neizostavni element svakog savremenog metrološkog sistema zahteva razvoj softvera, kao i korišćenje odgovarajućih alata. U metrologiji postaje sve zastupljeniji koncept udaljenih merenja, u kojem korisnik može dobiti uvid u rad određenog sistema korišćenjem mobilnog telefona, tableta, računara i sl., a takođe može i upravljati odgovarajućim procesima. Takođe, IoT (Internet of Things) koncept iziskuje pored hardverske platforme i stabilnu web aplikaciju. Kao rezultat pomenutih trendova, neophodno je napraviti edukativne platforme kako bi se studenti, kao i inženjeri, obučili za rad sa softverom, što ujedno predstavlja motivaciju za ovaj rad. Platforma koja je opisana u ovom radu primenjena je u praksi kroz realizaciju u predmetu „Web bazirani merno akvizicioni sistemi“.

Primeri koji se koriste u nastavi, namenjeni za savladavanje osnovnih tehnika front end razvoja i kompletan izvorni kod dati su na linku [1]. Primer jednog panela aplikacije je prikazan na slici 1.



Sl 1. Prikaz dinamički osvežavanih rezultata merenja u web aplikaciji

Na panelu sa slici 1. dat je primer prikazivanja rezultata u razvijenoj web aplikaciji. Panel se sastoji iz dva dela:

- grafičkog: gde su grafičkim putem prikazane vrednosti izmerene temperature u vremenu. Klikom kursora na grafičkom panelu dobijaju se podaci o odabranom odbirku.
- tekstualnog: gde su prikazani odbirci temperature u vremenu.

Razvojno okruženje koje se koristi je Microsoft Visual Studio Code, u daljem tekstu VS Code. VS Code radi na Windows-u, Mac OS-u i na Linux-u. Svi alati koji su korišćeni, besplatni su i jednostavni za konfigurisanje. HTML je korišćen za kreiranje web aplikacije, CSS za definisanje izgleda, a JavaScript za programiranje. Osim instalacije VS Code-a potrebno je instalirati Node.js®, okruženje u kom se JavaScript izvršava.

Na panelu na slici 2 je prikazana mogućnost isključivanja prikaza određene grupe podataka, npr. minimalnih i maksimalnih vrednosti, nakon čega se grafik automatski skalira po y osi. Na ovaj način dobija se na preglednosti rezultata kao i na njihovom međusobnom poređenju.

Sl 2. Prikaz funkcionalnosti koja omogućava selektivni grafički prikaz podataka

II. Prilagodljivi dizajn i Know-how

Savremeni internet pretraživači kao što su: Google Chrome, Mozilla Firefox, Apple Safari, Яндекс.Браузер, Microsoft Edge i razni drugi u većini slučajeva prikazuju napisanu aplikaciju baš onako kako je projektant to i zamislio. Kada se ista aplikacija otvori u staroj verziji Microsoft Internet Explorer-a, koji je bio aktuelan pre desetak godina - sledi iznenađenje. Iz navedenog razloga je pre samog kreiranja web aplikacije bitno odrediti ciljnu grupu, bilo da su to korisnici najnovijih Android ili iPhone uređaja iz 2019. ili je potrebno da web aplikacija radi besprekorno u Internet Explorer-u verzije 9 iz 2011. godine. Ciljna grupa ove web aplikacije su studenti koji aplikaciju koriste na računarima, koji imaju operativne sisteme novije generacije, a prilagodljivi dizajn je uveden da bi mogli da postave ovu aplikaciju na internet i da je slobodno koriste i na smartphone uređajima. Testiranje napisanog koda je bilo obavezno na različitim uređajima i u različitim internet pretraživačima i uvek su to radile bar dve osobe.

Web-bazirani merni sistem je razvijen kao koncept, koji zahvaljujući pomoćnim fajlovima koji se mogu preuzeti sa linka [1], omogućava studentu da relativno brzo prođe uvodnu front-end obuku, a zatim napravi web aplikaciju koja je funkcionalna i dobro izgleda na prosečnom laptop računaru sa ekranom rezolucije 1920 x 1080 px, kao i na mobilnom uređaju starije generacije koji ima rezoluciju npr. 480 x 800 px.

Telefoni iz vrhunskih serija (eng. flagship), iako imaju izuzetno velike rezolucije, umeju da stvaraju dodatne projektantske izazove. Npr. LG G3 iako ima rezoluciju od 1440 x 2560 px, nije sposoban da u portret režimu prikaže galeriju koja ima zadatu širinu od 800 px. Odgovor na to pitanje se dobije istraživanjem i informacijom da navedeni telefon ima rezoluciju od 480 x 853 dp i gustinu piksela 3. Upotreba savremenih jedinica mere kao što su dp (device independent pixels) i mnogih drugih su samo neke od stvari koje treba imati u vidu. Material.io [2] je online resurs koji između ostalog daje i smernice o dimenzijama ekrana mobilnih uređaja.

III. Korišćene tehnologije i alati za izradu materijala za vežbe

Za izradu edukativnog front-enda su korišćeni HTML 5, CSS 3 i JavaScript. Chart.js [3] je jedna u nizu besplatnih biblioteka koja je izabrana sa ciljem da omogući efektivan način za prilagodljivo iscrtavanje grafika u sklopu svakog panela. Medija upiti su upotrebljeni na takav način da se na ekranima širine do 1152 px prikazuje samo jedan panel, a preko toga, po dva panela u jednom redu. Od novijih alata, studentima je data i mogućnost da koriste i Brackets, koji omogućava brzo i lako kreiranje i testiranje web stranica i ima vrlo korisnu opciju koja se zove: "Live preview". Zbog edukativnog karaktera, veoma je bitno da u svakom trenutku HTML kod pude pravilno napisan. Da ne bi ručno tražili da li je napravljen propust u kodu, upotrebljen je efikasan alat za proveru [4], koji je kreiran od strane W3C (World Wide Web konzorcijuma). Ostavljena je i mogućnost da se prilikom dizajna izabere skladna paleta boja, uz pomoć Adobe Color Wheel online alat-a [5].

IV. Praktični razvojni primeri

Kompletan materijal pored edukativnog karaktera služi i za podsetnik za tehnički intervju. Niz primera je dat i mogu se prikazivati ili u web stranici ili u konzoli, a pošto su logički podeljeni i većina sadrži desetak linija koda, mogu se uklopiti u Microlearning. Između ostalog, za pisanje ovog rada su poslužile, dve knjige [6] i [7] i Pluralsight [8]. Funkcije i elementi JavaScript-a koji omogućavaju da se do detalja razume jedan ovakav web-bazirani merni sistem su: if else, switch case, push(), unshift(), pop(), shift(), propertiji objekta, do while petlja, while petlja, opseg funkcije, ključna reč this, prototipovi, value tipovi, reference tipovi, callback funkcije, IIFE (Immediately Invoked Function Expression), Function.apply(), Function.call(), Function.bind(), ternarni operator, setTimeout(), clearTimeout(), setInterval(), clearInterval(), Object.freeze(), Object.assign(), arrow funkcija, try catch finally, Array.reduce(), spread sintaksa (...), forEach(), map(), 4 načina za kreiranje objekta ({}, Object.create, new ključna reč, class), Closure, Promises, Iterators, Generators i Async/Await. Microlearning tehnika je korišćena iz praktičnih razloga, zato što se razumevanjem pojedinačnih funkcija, stiče i mogućnost sagledavanja šire slike i adaptacija front end rešenja.

Jedna od funkcija koja je sastavni deo web-baziranog mernog sistema je i CalculateMaxValue, koja je prikazana na slici 3.

```
function CalculateMaxValue(dataObject) {
    var maxValue;
    var dataArray = new Array;
    for (var o in dataObject) {
        dataArray.push(dataObject[o]);
    }
    maxValue = Math.max(...dataArray);
    return maxValue
}
```

Sl 3. CalculateMaxValue funkcija

Na primeru CalculateMaxValue funkcije se može videti da ona kao ulazne parametre dobija niz podataka, for petljom prolazi kroz svaku stavku, push() funkcijom ih dodaje u definisani dataArray niz, pomoću spread sintakse se niz prilagođava Math.max() funkciji, nakon čega funkcija CalculateMaxValue vraća brojnu vrednost koja predstavlja maksimalan broj od zadatog skupa brojeva.

Rezultati merenja koji se obrađuju i prikazuju, se nalaze na disku, u JSON formatu. JavaScript kod je prilagođen strukturi JSON fajla koji je prikazan na slici 4.

```
[
    {
        "Humidity": { "2018-10-18 02:20:00": 54.0,
            "2018-10-18 02:40:00": 53.0,
            "2018-10-18 03:00:00": 56.0},
        "Rainfall": {}, "WindGust": {},
        "Temperature": {}, "Pressure": {},
        "WindSpeed": {}, "WindDirection": {}
    }
]
```

Sl 4. Struktura rezultata merenja u JSON fajlu

V. PRIMER SPECIFIKACIJE ZAHTEVA

Potrebno je na jednoj stranici prikazati rezultate merenja sa tri različita senzora. Fajl sa svim rezultatima je "extractedData.json", a sadrži sledeće parametre: "Humidity, Rainfall, WindGust, Temperature, Pressure, WindSpeed i WindDirection." Obavezno je prikazati rezultate za WindGust i još sa dva senzora po izboru. Rezultate je potrebno prikazati u tabeli i na grafiku. Tabela treba da sadrži dve kolone, TIME i VALUE, a rezultati da budu prikazani u formatu, npr. "16.10.18. 11:40" i "960.40", respektivno. Prikazuju se svi rezultati, bez ikakvog filtriranja. Grafik treba da sadrži sve podatke, sortirane po vremenu. Opciono je da se prikažu minimalna, maksimalna ili srednja vrednost, na istom grafiku. Grafik treba da ima mogućnosti isključivanja prikaza seta parametara i automatsko prilagođavanje skale (Chart.js). Kao rezultat treba da se dobiju tri bloka koja u sebi sadrže i grafik i tabelu. Prilagoditi dizajn svih blokova, da budu u skladu sa prvim blokom. Izbor boja treba da se razlikuje od zadatog primera i potrebno je da bude čitko. Na rezolucijama do 1152 px je potrebno prikazivati jedan blok ispod drugog, dok je na većim rezolucijama potrebno prikazivati dva bloka, jedan pored drugog. HTML treba da bude personalizovan i da sadrži imena (polje "author") i brojeve indeksa (polje "keywords"). JavaScript fajl treba da sadrži isključivo kod koji je potreban za prikaz odabranih podataka, a nazivi promenljivih treba da budu smisleni. Zbog učitavanja fajlova sa lokalne mašine koristiti za razvoj Brackets sa opcijom "Live preview" ili neki drugi editor, uz Mozilla Firefox.

Rezultati merenja koji su obrađivani u ovom radu su preuzeti sa linka [9]. Ceo sistem ima edukativni karakter, a JavaScript je objektno orijentisan jezik, pa su u kodu date i smernice za refaktorisanje postojećeg koda i prikazane su na slici 5.

```
function Object_values(obj) {
    var vals = [];
    for (var prop in obj) {vals.push(obj[prop]);}
    return vals}

function MesurementUnit(keys, values) {
    var newUnit = {};
    this.keys = keys;
    this.values = values;
    return newUnit}

function createMyFirstObject(inputData) {
    outputData = new MesurementUnit();
    outputData.keys = Object.keys(inputData[0]);
    outputData.values = Object_values(inputData[0]);
    return outputData}
```

Sl 5.Objektno orijentisane smernice za refaktorisanje postojećeg koda

VI. PRIMENA APLIKACIJE U NASTAVI

Kako bi se spregnuo svet metrologije i softvera, na katedri za električna merenja uveden je predmet na IV godini studija pod nazivom "Web bazirani merno akvizicioni sistemi" čija je srž opisana web aplikacija. Naredni koraci predstavljaju nadograđivanje i usavršavanje metodoloških pristupa prilikom upoznavanja studenata sa novim softverskim alatima i konceptima. Pokazano je u praksi da je projektni rad takođe neizostavna celina koju je neophodno da imaju studenti inženjerskih nauka na višim godinama studija. Ovakav pristup otvara mogućnost da studenti dobiju detaljniji i sveobuhvatniji uvid u inženjerski način razmišljanja. Jedan od predloga može biti projektovanje mikrokontrolerskog sistema za merenje/nadgledanje odgovarajućeg procesa gde je neophodno da se upotrebi poznavanje hardvera, firmvera i softvera, kao i njihovu integraciju i pravilnu sinhronizaciju.

Kroz naredne ispite moguće je izvršiti detaljnije upozavanje studenata sa dodatnim razvojnima alatima. Moguće je dodati bazu podataka umesto upisivanja u postojeći fajl, merenje i prikaz rezultata u realnom vremenu, povezivanje više pomenutih mikrokontrolerskih sistema u jednu celinu itd.

Veliki broj zahteva ostavlja dovoljno prostora mentoru da na adekvatan način i izvrši ocenjivanje projektnog zadatka, gde bi svaki zahtev nosio odgovarajući broj bodova pri formiranju konačne ocene.

VII. ZAKLJUČAK

U radu je dat opis web aplikacije koja se može koristiti u različitim metrološkim konceptina poput IoT, pametne kuce, konceptu udaljenih merenja... Aplikacija predstavlja edukativnu platformu za savladavanje osnovnih softverskih web alata.

HTML 5 je upotrebljen za izradu strukture sadržaja zato što omogućava efikasno dodavanje dinamičkog sadržaja. Zbog redukovanja kompleksnosti, za stilizovanje web stranice je

umesto SASS-a korišćen CSS. Takođe, zbog redukovanja kompleksnosti aplikacija ne koristi Angular framework, već je napisana u čistom JavaScript-u (ECMAScript 6). Prilikom pisanja aplikacije akcenat je stavljen na modularnost i na upotrebu open source tehnologija. Pored mnoštva modernijih jedinica mere, za veličinu prikaza je korišćen pixel (px). Takođe, dat je i niz primera koji omogućavaju da se svako parče ove aplikacije može efikasnije analizirati. Autori se aktivno trude da koriste tzv. cutting edge tehnologije i logički dodatak na ovu aplikaciju je trenutno u fazi razvoja, gde se kao back-end koristi .NET Core tehnologija i SignalR middleware, koji pored već atraktivnog načina prikazivanja, nude i mogućnost prikazivanja rezultata u realnom vremenu. Funkcionalnost front-enda će u narednim verzijama biti proširena sa medija upitima koji su prilagođeni gledanju rezultata merenja na papiru.

ABSTRACT

In this paper, an example of a front-end module which shows measuring results from seven different sensors in a responsive manner is described. Responsive part enables that results can be viewed easily from PCs and from portable devices. Every sensor has a separate panel. On high resolutions, two panels are shown in one row, on portable devices panels are stacked. Each panel shows a list of measuring results with adequate time values, at the same time, for easier monitoring purposes graph with all values is shown. Each of the basic examples which contain programming code written in JavaScript, given as an addition to this paper is made in the way that can be dealt with in less than 15 minutes. Besides educational character this concept is compatible with basic Microlearning principles.

Web-based measuring system - educational front-end

Međuprovera EMC analizatora spektra između dva etaloniranja

Aleksandar M. Kovačević, Nenad Munić, Veljko Nikolić, Ljubiša Tomić, Ivana Kostić

***Apstrakt*—Međuprovera EMC analizatora spektra između dva etaloniranja prikazana je u ovom radu. Međuprovera je bila potrebna da bi se održalo poverenje u status etaloniranja EMC analizatora spektra. Pri tome, ta provera se obavlja u skladu sa utvrđenom procedurom.**

***Ključne reči*—Međuprovera; EMC analizator spektra; poverenje u etaloniranje.**

I. Uvod

SVA oprema koja se koristi za ispitivanja, uključujući opremu za pomoćna merenja (npr. za uslove okoline), a koja bitno utiče na tačnost ili valjanost rezultata ispitivanja, mora da bude etalonirana pre puštanja u upotrebu [1]. Pri tome, laboratorija mora da uspostavi program i proceduru za etaloniranje svoje opreme. U skladu sa utvrđenim programima i procedurama, moraju se obavljati neophodne međuprovere radi održavanja poverenja u status etaloniranja [1].

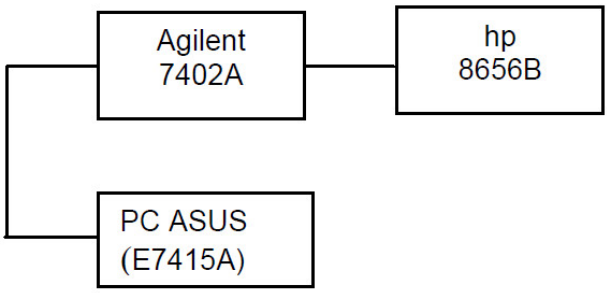
Odeljenje za elektromagnetsku kompatibilnost i uticaje okoline je akreditovano u oblasti ispitivanja elektromagnetske kompatibilnosti (u daljem tekstu Odeljenje za EMC i uticaje okoline) u okviru Centra za ispitivanje proizvoda, Tehnički opitni centar (TOC) iz Beograda [2]. Tako, Odeljenje za EMC i uticaje okoline svake godine vrši periodične preglede (međuprovere) svoje ključne opreme, a na osnovu izrađenog Plana pregleda ključne merne opreme za tu godinu. Naime, u TOC-u je izrađen dokument Uputstvo o metrološkom obezbeđenju Tehničkog opitnog centra [3] u skladu sa standardom SRPS ISO/IEC 17025:2017 [1], na osnovu koga je uspostavljen program i procedura za etaloniranje sopstvene opreme. Pri tome, Odeljenje je izradilo Plan pregleda ključne merne opreme, koja se periodično pregleda između dva etaloniranja za 2018. godinu [4]. Tako, za EMC analizator spektra E7402A, „AGILENT“, u Planu je naveden period etaloniranja od 1 godine i period internog pregleda (međuprovera) od 6 meseci, koji su određeni na osnovu dokumenata Normativ vremena baždarenja i verifikacije etalona i mernih sredstava na upotrebi u VJ [5] i Procedure za preispitivanje rokova periodičnog etaloniranja merne oprema TOC [6]. Na osnovu Plana, kao i standarda SRPS ISO/IEC 17025:2017 [1], izvršen je periodični pregled (međuprovera) EMC analizatora spektra E7402A, „AGILENT“, između dva etaloniranja (etaloniran 09.05.2018. godine, Zapisnik br. 2-138/18, akreditovana metrološka laboratorija TOC-a).

Cilj međuprovere je da, na osnovu analize dobijenih rezultata i zadatog kriterijumima, Odeljenje za elektromagnetsku kompatibilnost i uticaje okoline održi poverenje u status etaloniranja EMC analizatora spektra E7402A, „AGILENT“.

Aleksandar M. Kovačević, Nenad Munić, Veljko Nikolić, Ivana Kostić – Tehnički opitni centar, Generalštab Vojske Srbije, Vojvode Stepe 445, 11000 Beograd, Srbija (e-mail: aleksandarkovacevic1962@yahoo.com). Ljubiša Tomić – Vojnotehnički Institut, Ratka Resanovića 1, 11000 Beograd, Srbija (e-mail: ljubisa.tomic@gmail.com).

II. Uslovi međuprovere

Periodični pregled (međuprovera) EMC analizatora spektra E7402A, „AGILENT“, između dva etaloniranja (etaloniran 09.05.2018. godine, Zapisnik br. 2-138/18), izvršen je dana 15.11.2018. godine u ekranizovanoj sobi (Faradejev kavez). Pri tome, kao izvor signala korišćen je signal generator hp 8656B. Za potrebe međuprovere korišćen je stoni računar ASUS sa aplikacijom za automatizaciju merenja (EMC Measurement Application E7415A). Šema povezivanja merne opreme (merila) za međuproveru je data na Sl. 1.



Sl. 1. Šema povezivanja merne opreme za međuproveru.

Periodični pregled (međuprovera) EMC analizatora spektra E7402A je obuhvatio sledeće:

1. Provera tačnosti merenja nivoa signala, pri zadatoj vrednosti nivoa ulaznog signala i različitim vrednostima frekvencije;
2. Provera tačnosti merenja nivoa signala, pri konstantnoj vrednosti frekvencije i različitim vrednostima nivoa ulaznog signala.

Provera tačnosti merenja nivoa signala, za različite vrednosti frekvencije (videti Tabelu 1), vršena je u frekvencijskom opsegu od 100 kHz do 990 MHz, pri zadatoj

vrednosti nivoa ulaznog signala od – 10 dBm iz signal generatora.

Provera tačnosti merenja nivoa signala, za različite vrednosti nivoa ulaznog signala iz signal generatora, od – 80 dBm do + 10 dBm, vršena je na frekvencijima od 80 MHz i od 800 MHz, respektivno.

Za navedena merenja korišćena su sledeća merna sredstva i oprema:

- Signal generator hp 8656B, „HEWLETT PACKARD“, od 100 kHz do 990 MHz,
- EMC analizator spektra E7402A, „AGILENT“, od 100 Hz do 3 GHz,
- Stoni računar ASUS sa aplikacijom za automatizaciju merenja (EMC Measurement Application E7415A)
- Kabl RG-214/U.

Pri tome, karakteristike merne opreme zadovoljavaju propisani standard [7].

Uslovi okoline:

- temperatura okoline: 21 °C ± 2 °C,
- relativna vlažnost vazduha: 65 % ± 15 %.

III. Kriterijum za ocenu rezultata međuprovere

Za ocenu rezultata međuprovere korišćena je sledeća formula:

$$a_{\text{zad}} - U_m \le a_{\text{iz}} \le a_{\text{zad}} + U_m \qquad (1)$$

gde su:

a_{zad} – zadati nivo ulaznog signala (dBm),

a_{iz} – izmereni nivo ulaznog signala (dBm),

U_{m} – proširena merna nesigurnost provere tačnosti nivoa signala (za faktor proširenja ili prekrivanja $k = 2$).

Kao kriterijum za ocenu uspešnosti rezultata međuprovere uzeta je zadovoljenost formule (1).

Ukoliko je zadovoljenost formule (1) ispunjena, smatra se da je funkcionalnost EMC analizatora spektra E7402A – Agilent u periodu između dva etaloniranja očuvana, pa nema potrebe za korektivnim merama. Međutim, ukoliko zadovoljenost formule (1) nije ispunjena, potrebno je uvesti korektivne mere (vanredno etaloniranje, opravka, rashodovanje i sl.) [3].

IV. Rezultati međuprovere

Rezultati međuprovere se odnose na: 1) Proveru tačnosti merenja nivoa signala, pri zadatoj vrednosti nivoa ulaznog signala i različitim vrednostima frekvencije, 2) Proveru tačnosti merenja nivoa signala, pri konstantnoj vrednosti frekvencije i različitim vrednostima nivoa ulaznog signala.

Rezultati provere tačnosti merenja nivoa signala, za različite vrednosti frekvencije, u frekvencijskom opsegu od 100 kHz do 990 MHz, pri zadatoj vrednosti nivoa ulaznog signala od – 10 dBm iz signal generatora, dati su u Tabeli 1.

TABELA I

VREDNOSTI NIVOA SIGNALA ZA RAZLIČITE VREDNOSTI FREKVENCIJE, PRI ZADATOJ VREDNOSTI NIVOA ULAZNOG SIGNALA IZ SIGNAL GENERATORA

Zadata frekvencija [MHz]	Izmereni nivo (a_{iz}) [dBm]
0,1	-10,26
1	-10,59
50	-10,72
100	-10,22
150	-10,44
200	-10,79
300	-9,98
400	-9,92
600	-9,93
800	-9,63
900	-9,78

TABELA II

VREDNOSTI NIVOA SIGNALA NA FREKVENCIJI OD 80 MHZ, ZA RAZLIČITE VREDNOSTI NIVOA ULAZNOG SIGNALA IZ SIGNAL GENERATORA

Zadati nivo (a_{zad}) [dBm]	Izmereni nivo (a_{iz}) [dBm]
10	10,23
0	0,14
-10	-10,23
-20	-20,44
-30	-30,27
-40	-40,37
-50	-50,91
-60	-60,77
-70	-70,29
-80	-80,21

TABELA III

VREDNOSTI NIVOA SIGNALA NA FREKVENCIJI OD 800 MHZ, ZA RAZLIČITE VREDNOSTI NIVOA ULAZNOG SIGNALA IZ SIGNAL GENERATORA

Zadati nivo (a_{zad}) [dBm]	Izmereni nivo (a_{iz}) [dBm]
10	10,19
0	0,61
-10	-10,32
-20	-20,14
-30	-30,29
-40	-40,71

TABELA IV
KONAČNI PRORAČUN MERNE NESIGURNOSTI ZA SLUČAJ PROVERE TAČNOSTI MERENJA NIVOA SIGNALA

Uticajna veličina X_i	**Procena** X_i (x_i)		**Standardna nesigurnost** $u(x_i)$	**Koeficijent osetljivosti** c_i	**Doprinos standardnoj nesigurnosti** $u_i(y)=c_i\,u(x_i)$
	Vrednost [dB]	**Funkcija raspodele**			
Pokazivanje analizatora spektra	±0,1	pravougaona, k = 1,732	0,058	1	0,058
Tačnost prijema sinusnog signala na analizatoru spektra	±1,0	normalna, k = 2,000	0,500	1	0,500
Slabljenje kablova	±0,2	normalna, k = 2,000	0,1	1	0,100
Tačnost zadate vrednosti sinusnog signala iz signal generatora	±1,0	normalna, k = 2,000	0,500	1	0,500
Kombinovana standardna nesigurnost $u_c(y)$		normalna	$u_c(y) = \sqrt{\sum_i u_i^2(y)}$		0,716
Proširena merna nesigurnost U_m		normalna, k = 2	$U_m = k u_c(y)$		**1,43**

Rezultati provere tačnosti merenja nivoa signala na frekvenciji od 80 MHz, za različite vrednosti nivoa ulaznog signala iz signal generatora od – 80 dBm do + 10 dBm, respektivno, dati su u Tabeli 2. Dok su rezultati provere tačnosti merenja nivoa signala na frekvenciji od 800 MHz, za različite vrednosti nivoa ulaznog signala iz signal generatora od – 80 dBm do + 10 dBm, respektivno, dati u Tabeli 3.

Pri tome, konačni proračun merne nesigurnosti za slučaj provere tačnosti merenja nivoa signala, tip B, koji je prikazan u Tabeli 4, izračunat je u skladu sa smernicama datim u [8, 9], i odnosi se na najgori slučaj provere tačnosti merenja nivoa signala. U navedenoj tabeli, vrednosti za uticajne veličine (pokazivanje analizatora spektra, tačnost prijema sinusnog signala na analizatoru spektra, tačnost zadate vrednosti sinusnog signala iz signal generatora, slabljenje kablova) su dobijene iz proizvođačke specifikacije i kalibracionih sertifikata (uverenja o etaloniranju).

Iz Tabele 4 se vidi da proširena merna nesigurnost U_{m} iznosi 1,43 dB.

Kada se ubace vrednosti date u Tabelama 1, 2, 3, respektivno, kao i za U_{m}, u formulu (1), može se konstatovati da je zadovoljenost iste ispunjena. Na taj način, smatra se da je funkcionalnost EMC analizatora spektra E7402A – Agilent u periodu između dva etaloniranja očuvana, pa nema potrebe za korektivnim merama.

V. ZAKLJUČAK

Međuprovera merne opreme se koristi da akreditovana laboratorija održi poverenje u status etaloniranja iste.

Odeljenje za elektromagnetsku kompatibilnost i uticaje okoline iz Tehničkog opitnog centra iz Beograda, koje je akreditovano u oblasti ispitivanja elektromagnetske kompatibilnosti (EMC), svake godine vrši periodične preglede (međuprovere) svoje ključne opreme, na osnovu izrađenog Plana pregleda ključne merne opreme za tu godinu. Tako, Odeljenje je izradilo Plan pregleda ključne merne opreme, koja se periodično pregleda između dva etaloniranja za 2018. godinu, na osnovu koga je izvršen periodični pregled (međuprovera) EMC analizatora spektra E7402A, „AGILENT“, između dva etaloniranja, a u skladu sa standardom SRPS ISO/IEC 17025:2017. Pri tome, rezultati međuprovere se odnose na: 1) Proveru tačnosti merenja nivoa signala, pri zadatoj vrednosti nivoa ulaznog signala i različitim vrednostima frekvencije, 2) Proveru tačnosti merenja nivoa signala, pri konstantnoj vrednosti frekvencije i

različitim vrednostima nivoa ulaznog signala. Kao kriterijum za ocenu uspešnosti rezultata međuprovere uzeta je zadovoljenost formule (1). Cilj međuprovere je da, na osnovu analize dobijenih rezultata i zadatog kriterijumima, Odeljenje za EMC i uticaje okoline održi poverenje u status etaloniranja EMC analizatora spektra E7402A, „AGILENT“.

Kako je konstatovano da je zadovoljenost formule (1) ispunjena, smatra se da je funkcionalnost EMC analizatora spektra E7402A – Agilent u periodu između dva etaloniranja očuvana, pa nema potrebe za korektivnim merama.

ZAHVALNICA

Želeli bi da se zahvalimo Marijani Ferlan i Teodori Knežević iz TOC-a na obradi rezultata.

Automatizacija merenja nivoa imunosti na kondukcione smetnje

Nenad Munić, Aleksandar Kovačević, Vladimir Jokić, Veljko Nikolić, Ljubiša Tomić

***Apstrakt*— Merenje nivoa imunosti na kondukcione smetnje je karakteristika koja je značajna za većinu naoružanja i vojne opreme. Zahtevi i metode merenje nivoa imunosti su definisani domaćim standardima odbrane SORS 1029/89 i SORS 1762/89, respektivno, za koje postoji objektivna potreba da se osavremene u skladu sa aktuelnim međunarodnim standardima iz te oblasti. Shodno tome, koristeći standard MIL-STD-461F, u laboratoriji za EMC Tehničkog opitnog centra, pristupilo se prilagođavanju zahteva i metoda merenja nivoa imunosti na kondukcione smetnje iz navedenih domaćih vojnih standarda. Pri tome, prilagođavajući metode merenja raspoloživoj mernoj opremi laboratorije. U ovom radu će postupno biti prikazan razvoj jednog automatizovanog mernog mesta za merenje nivoa imunosti na kondukcione smetnje, kroz poseban osvrt na sledeće faze: kalibracija i ispitivanja.**

***Ključne reči*—Elektromagnetska smetnja; nivo imunosti; kondukcione smetnje.**

I. Uvod

JEDNA od karakteristika koja se meri tokom ispitivanja naoružanja i vojne opreme (NVO) u Tehničkom opitnom centru (TOC) [1] je nivo imunosti na elektromagnetske smetnje. Nivo imunosti je zapravo najviši nivo elektromagnetske smetnje koja deluje na uređaj, a pri kojem uređaj još uvek radi sa zahtevanim performansama [2]. Postoje dva načina kako se prilikom ispitivanja elektromagnetska smetnja prenosi do ispitivanog uređaja: pretežno slobodnim elektromagnetskim talasom, što predstavlja radijacione smetnje i pretežno vođenim talasom, duž provodnika (kablovima), što predstavlja kondukcione smetnje [3]. U zavisnosti od načina prenosa razlikujemo dve vrste merenja nivoa imunosti: merenja nivoa imunosti na radijacione smetnje i merenja nivoa imunosti na kondukcione smetnje.

Zahtevi i metode merenja nivoa imunosti su navedeni u domaćim standardima odbrane Republike Srbije SORS 1029/89 [4] i SORS 1762/89 [5], respektivno. Naime, to su standardi koji su usvojeni pre 30 godina i koji su izrađeni na osnovu američkog vojnog standarda MIL-STD-461B [6] iz 1980. godine. Od tada je Američki standard, usled ubrzanog razvoja električnih, elektronskih i elektromehaničkih sredstava NVO, pretrpeo brojne revizije (aktuelna „G“ revizija MIL standarda je iz 2015. godine), dok se domaći standardi nisu menjali.

Zbog toga, definisan je cilj da se, u skladu sa novijim međunarodnim vojnim standardima MIL-STD-461F [7], usklade zahtevi i metode merenja domaćih standarda SORS 1029/89 i SORS 1762/89. Ispitivanja imunosti na radijacione smetnje ili ispitivanja imunosti na polje EM smetnji [4] su u prethodnom periodu usklađena i rezultati su prikazani javnosti [8]. Takođe, potrebno je bilo to isto uraditi i po pitanju imunosti na kondukcione smetnje ili imunosti na kondukcione EM smetnje [4].

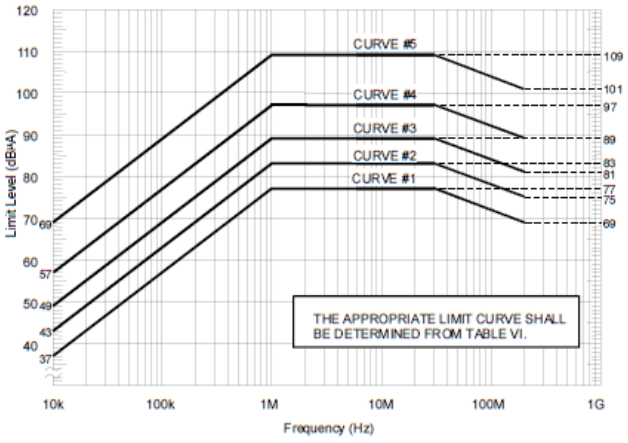
Predmet ovog rada je usavršavanje zahteva i metoda merenja nivoa imunosti na kondukcione smetnje standarda SORS 1029/89 i SORS 1762/89, sa aktuelnom verzijom standarda MIL-STD-461F, CS114 (eng. CS – conducted susceptibility). Pri tome, bilo je potrebno, u što većem obimu, automatizovati merenja, uz korišćenje postojeće merne opreme laboratorije za EMC.

Automatizacija merenja je realizovana u programskom paketu MATLAB [9] koristeći ugrađen „Instrument Control Toolbox“.

II. Merenje nivoa imunosti na kondukcione smetnje

Imunost na kondukcione smetnje se u domaćim vojnim standardima definiše kao sposobnost sredstva NVO da radi bez neželjenih odziva, pri delovanju definisanih EM smetnji, koje se prostiru duž provodnika [4].

Postojeći zahtevi i metode merenja imunosti na kondukcione smetnje su definisani u domaćim standardima SORS 1029/89 i SORS 1762/89 (zahtevi i metode za: iks1 i iks2), i njih je bilo neophodno usaglasiti sa metodom CS114 američkog vojnog standarda MIL-STD-461F.



Sl. 1. Nivoi imunosti na kondukcione smetnje (strujne smetnje) prema MIL-STD-461F, CS114 [7].

Da bi se postigao što tačniji nivo elektromagnetske smetnje, merenja nivoa imunosti smetnji (u našem slučaju kondukcionih) se rade u Faradejevom kavezu. Time se

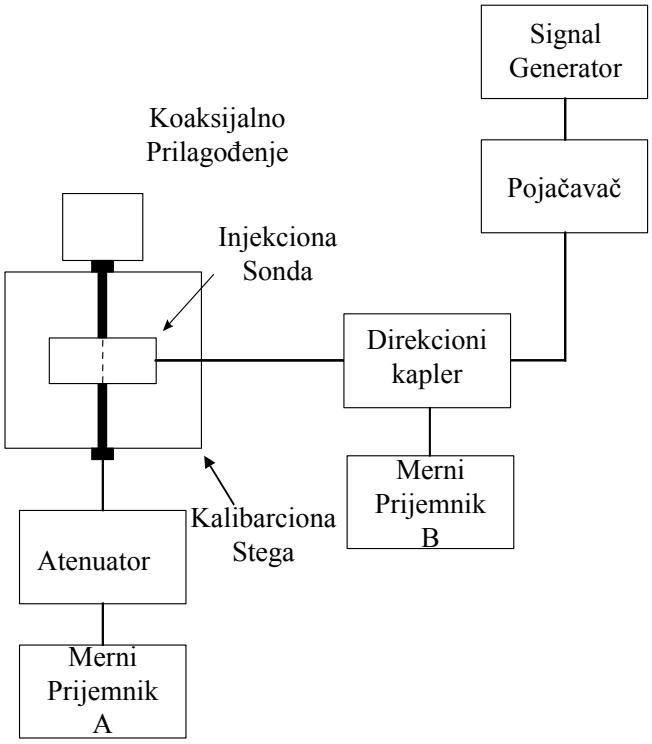
Vladimir Jokić, –Tehnički opitni centar, Vojvode Stepe 445, 11000 Beograd, Srbija (e-mail: vlada0806@yahoo.com).
Veljko N. Nikolić, – Tehnički opitni centar, Vojvode Stepe 445, 11000 Beograd, Srbija (e-mail: veljkozmaj@yahoo.com).
Ljubiša Tomić – Vojnotehnički Institut, Ratka Resanovića 1, 11000 Beograd, Srbija (e-mail: ljubisa.tomic@gmail.com).

neutrališe eventualni uticaj elektromagnetske sprege između provodnika uređaja ili opreme koji se testira (EUT) i spoljašnjeg ambijentalnog elektromagnetskog polja. Pri ispitivanjima se kondukcione smetnje dovode u napojni kabl EUT-a. Zahtevi za nivo imunosti (struja kalibracije) su preuzeti iz standarda MIL-STD-461F, CS114, i prikazani su na sl. 1. Sa slike se može videti da postoji ukupno pet nivoa strujnih smetnji. Nivo smetnje se bira pre merenja i određuje se na osnovu namene i mesta ugradnje EUT-a. Jednom odabrani nivo se koristi i prilikom kalibracije mernog sistema i ispitivanja EUT-a.

Pri merenjima laboratorijski uslovi okoline su: temperatura okoline od 21° C ± 2° C, relativna vlažnost vazduha: 65 % ± 15 %.

III. KALIBRACIJA

Blok dijagram konfiguracije kalibracionog mernog mesta za ispitivanje imunosti na kondukcione smetnje, prema standardu MIL-STD-461F, CS114, prikazan je na sl. 2. Sa slike se vidi da se tokom kalibracije koristi direkcioni kapler, kojim se zapravo monitoriše ukupno predata RF snaga injekcionoj sondi kada je ona spregnuta u kalibracionu stegu i na izlazu te stege zatvorena sa koaksijalnim prilagođenjem, u ovom slučaju otpornikom od 50 Ω (videti sl. 3). Te vrednosti predate snage se pamte i koriste kao referentne vrednosti predajne snage, tokom ispitivanja EUT-a, kada se injekciona sonda umesto kalibracione strukture spreže sa naponskim provodnikom (kablom) EUT-a i tom prilikom se kontroliše i održava isti nivo predate snage.

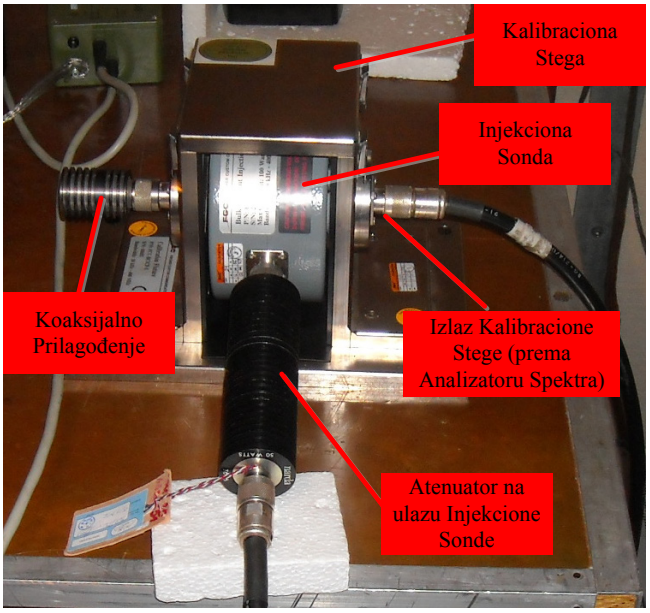


Sl. 2. Konfiguracija mernog mesta za kalibraciju, prema MIL-STD-461F CS114 [7].

Nažalost, TOC u svojoj mernoj opremi nema direkcioni kapler odgovarajuće snage i frekvencije, pa je monitorisanje predajne snage realizovano monitorisanjem nivoa izlazne snage signal generatora. Pri tome, monitorisanje se vrši za svaku frekvenciju iz mernog opsega frekvencija.

Prilikom kalibracije, za merenje nivoa injektovane struje koristi se analizator spektra (na sl. 3 označen kao Merni prijemnik A), pre kojeg je postavljen atenuator. Atenuator se koristi dvojako: radi zaštite od oštećenja analizatora spektra od previsokog ulaznog nivoa signala i radi boljeg prilagođenja analizatora spektra prema kalibracionoj strukturi.

Na analizatoru spektra je potrebno izabrati da se rezultati merenja izražavaju u jedinicama dBμA, gde se, pri tome, podrazumeva da se koristi ostala merna opremu iste karakteristične impedanse od 50 Ω, kao što je kod analizatora spektra.



Sl. 3. Injekciona sonda spregnuta u kalibracionu strukturu i zatvorena sa prilagođenjem od 50 Ω.

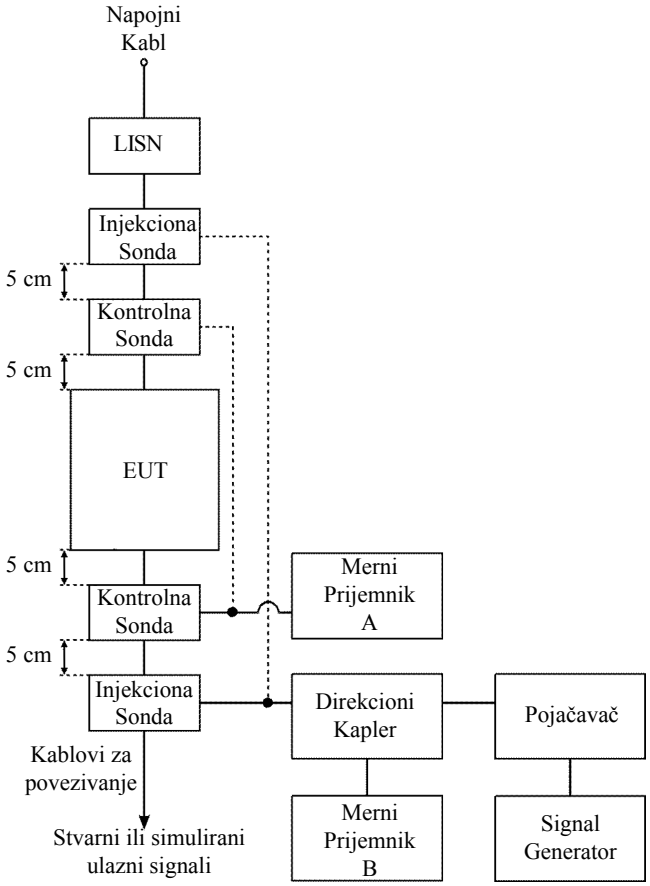
Tokom merenja, za svaku frekvenciju se očitava nivo injektovane struje i po potrebi se nivo snage signal generatora podiže ili smanjuje, tako da nivo struje bude takav da je veći od nivoa zahtevanog standardom, ali i da maksimalno premašenje tog nivoa ne bude veće od 1 dB. Nivo maksimalnog premašenja nije definisan standardom, ali je, u ovom slučaju, dobijen iskustveno, težeći da se broj iteracija prilagođavanja izlazne snage generatora prema merenom nivou injektovane struje smanji na što je moguće manji broj, čime se postiže razumno vreme trajanja kalibracije, a pri tome je maksimalna procentualna vrednost premašenja snage manja od 26%. Postignuto je da se kalibracija na svakoj frekvenciji uradi u maksimalno 3 koraka (iteracije), mada za većinu frekvencija se ona uradi u jednom koraku.

Za realizaciju ovog ispitivanja, usled velikog broja ispitnih frekvencija i složenosti merenja (paralelan rad sa više uređaja), bilo je neophodno izvršiti automatizaciju merenja. Time se trajanje ispitivanja skraćuje, a smanjuje se i mogućnost da usled ljudskog faktora dođe do greške pri merenjima.

IV. ISPITIVANJE

Za razliku od kalibracije kada se injekciona sonda povezuje na kalibracionu stegu, kod ispitivanja se ona

postavlja oko naponskog provodnika (kabla) EUT-a. Takođe, na istom provodniku, na rastojanju od 5 cm, postavlja se kontrolna sonda kojom se monitorišu nivoi injektovanih struja smetnji. Konfiguracija ovog merenja, prema standardu MIL-STD-461G, CS114, prikazana je na sl. 4. Iz istog razloga kao kod kalibracije, i kod ispitivanja EUT-a se ne koristi direkcioni kapler za monitorisanje nivoa predate snage injekcionoj sondi, već se prati izlazna snaga signal generatora. Postavljanjem kalibracionih vrednosti izlazne snage na signal generatoru se postižu ispitni uslovi, pri kojima je moguće posmatrati ili meriti funkciju EUT-a ili tražiti neki neželjeni odziv.

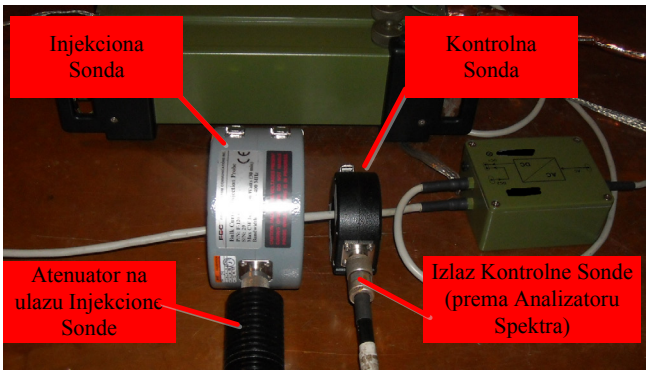


Sl. 4. Konfiguracija mernog mesta za ispitivanje uređaja koji se testira, prema MIL-STD-461F, CS114 [7].

Prilikom sprege injekcione sonde sa kalibracionom stegom, odnosno postavljanjem oko napojnog provodnika ili kabla EUT-a, javljaju se različite impedanse gledano od strane injekcione sonde prema analizatoru spektra. To može da dovede do različitih nivoa struje koja se injektuje prilikom kalibracije, odnosno ispitivanja. Naime, ako je impedansa u kolu sa EUT veća od one u kalibracionom kolu, onda nivo injektovane struje u provodniku će biti manji od one dobijene kalibracijom. Nasuprot toga, ukoliko je impedansa u kalibracionom kolu veća, onda injektovana struja može preći maksimalno dozvoljen nivo standardom i tada se u toku ispitivanja mora smanjiti snaga na signal generatoru. Tek kada se snaga dovoljno smanji, tako da vrednost injektovane struje bude u skladu sa standardom, onda se prati ispravnost funkcija EUT-a. Praćenje funkcije EUT-a podrazumeva traženje određenih indikatora degradacije ili prestanka rada EUT-a. Način kako se to utvrđuje zavisi od vrste uređaja i može se pratiti kroz: ugrađene „built-in-test“ (BIT) procedure, vizuelnim posmatranjem, slušanjem ili merenjem pojedinih izlaznih signala uređaja. Taj deo ispitivanja nije ponovljiv, tj. za svaki uređaj je različit, te se stoga on ne automatizuje. Pri tome, ispitivač ručno upisuje na kojim frekvencijama se javlja degradacija, te se na tim frekvencijama kasnije, ručnim merenjima, utvrđuje tačan nivo imunosti.

Za razliku od kalibracije kada je signal sa signal generatora sinusoidan, kod ispitivanja on je modulisan [6]. Način modulacije zavisi od tipa ispitivanog sredstva [5]. Tako na primer: za FM prijemnike se bira FM modulacija, za AM prijemnike AM modulacija, dok za većinu ostalih sredstava se bira impulsna odnosno amplitudska modulacija. Tom prilikom se u zavisnosti od parametara modulacije teži održavanju kalibracione vrednosti izlazne snage, modulisanog signala. Ukupno vreme izlaganja EUT-a na svakoj frekvenciji je ne manje od 3 s.

Tokom kalibracije i ispitivanja se vode automatizovani zapisi o nivoima injektovane struje u zavisnosti od frekvencije. Ispitivanje se ponavlja za svaki fazni napojni provodnik pojedinačno, isključujući povratni provodnik, uzemljenje i komplet napojnog kabla sa provodnicima (obuhvatom). Primer ispitivanja jednog EUT-a je prikazan na sl. 5.



Sl. 5. Deo merne postavke koji se koristi tokom ispitivanja uređaja.

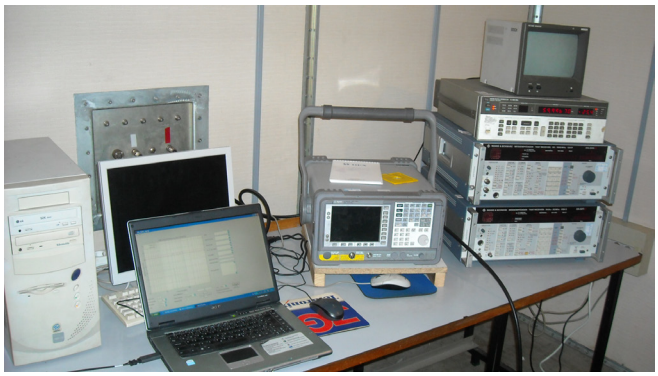
V. PRAKTIČNA REALIZACIJA AUTOMATIZOVANOG MERNOG MESTA ZA MERENJE NIVOA IMUNOSTI NA KONDUKCIONE SMETNJE

U ovom slučaju, proces merenja je automatizovan pisanjem koda u programskom paketu MATLAB [9]. Da bi se omogućila kontrola merne opreme, u MATLAB je instaliran dodatak „Instrument Control Toolbox”. Kao hardver za pokretanje MATLAB programa, moguće je koristiti PC računar ili laptop. Komunikacija između merne opreme i računara se obavlja preko HPIB (GPIB) magistrale. Za komunikaciju GPIB magistrale i USB porta računara koristi se „USB to GPIB“ adapter 82357B. Sam softver je namenski razvijen za potrebe ovog ispitivanja i omogućava realizaciju kalibracije i ispitivanja. Da bi adapter funkcionisao, mora se u operativnom sistemu instalirati odgovarajući drajveri, koji taj adapter podržavaju.

Za navedena merenja korišćena merna sredstva i oprema navedena u tabeli 1. Pri tome, karakteristike merne opreme zadovoljavaju propisani standard [10].

Pri pokretanju programa treba prvo izvršiti inicijalizaciju GPIB magistrale, zatim kreiranje objekta za rad sa GPIB magistralom, otvaranje tog objekta i zadavanje određenog

seta komandi. Treba voditi računa da stariji instrumenti ne podržavaju standardizovani set komandi (SCPI), te ako se oni ipak koriste tada nije moguća prosta promena nekog instrumenta drugim, bez prethodne izmene samog koda programa i prilagođavanja seta komandi instrumenta.



Sl. 6. Merna oprema koja se koristi za pravljenje automatizovanog mernog mesta.

U konkretnom slučaju treba da se kontrolišu dva instrumenta: signal generator i analizator spektra. Zbog toga je neophodno kreirati dva objekta kojima se ti instrumenti mogu nezavisno kontrolisati. Trebalo predvideti normalno funkcionisanje programa pri raznim slučajevima, kao na primer pri kalibraciji, kada nije moguće dobiti zahtevani nivo struje smetnji, a na signal generatoru je postavljen maksimalni nivo snage. Tada bi program očito upao u beskonačnu petlju, jer ne može da se ispuni uslov o zahtevanom nivou struje, ali se tada mogu definisati određene rutine, tako da se omogući ipak prelazak na sledeću frekvenciju, na primer tako što se za nivo imunosti na toj frekvenciji uzima maksimalno postignut nivo struje.

TABELA I
MERNA OPREMA ZA MERENJE NIVOA IMUNOSTI NA KONDUKCIONE SMETNJE

Naziv instrumenta	Proizvođač	Tip	serijski broj

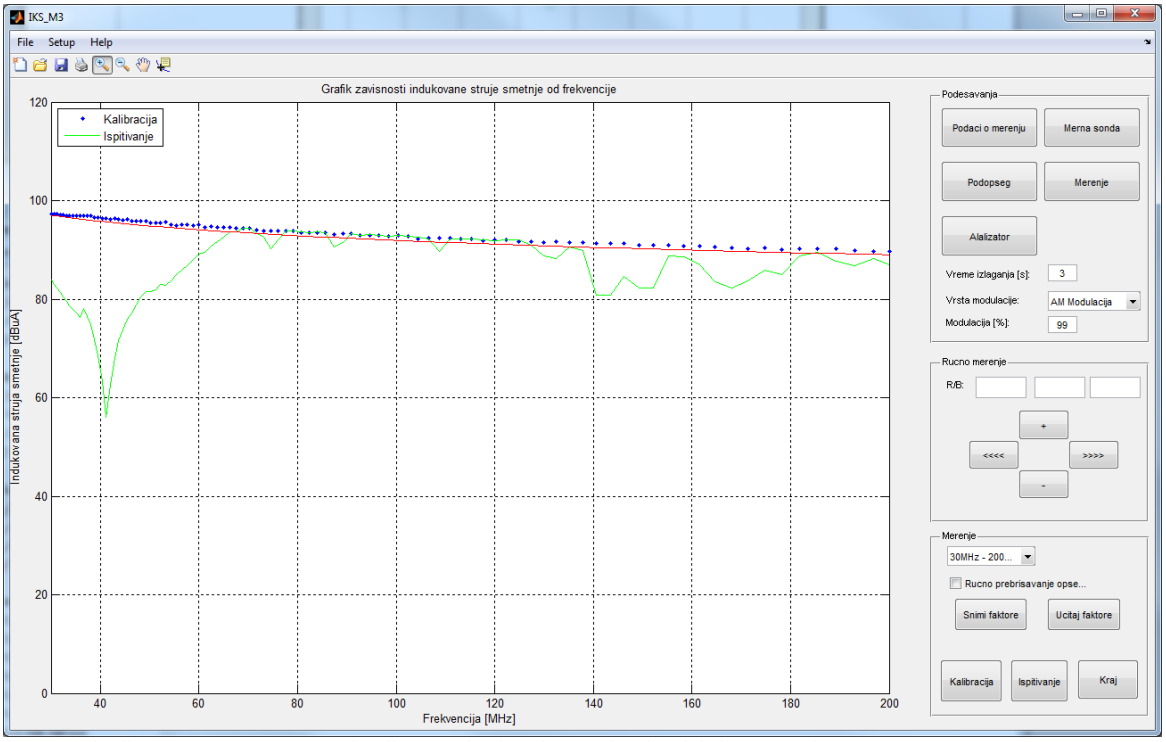
RF i optički kablovi	/	RGU 214	/

Nivoi injektovane struje prilikom kalibracije i ispitivanja se pamte u promenljive i grafički se prikazuju kroz dijagram nivoa struje smetnji u zavisnosti od frekvencije (sl. 7). U slučaju neke nepravilnosti rada uređaja na nekoj frekvenciji, ta frekvencija se ručno upisuje van programa. Pri tome, po završetku prebrisavanja kompletnog podopsega, ručno vođenim postupkom (poluautomatski), kroz softverski zadate komande, dalje bi se izvršilo očitavanje minimalnog nivoa struje, gde dolazi do pogoršavanja rada EUT-a, kao i učitavanja nivoa struje kada uređaj ponovo uspostavi ispravnu funkciju. Nakon završetka ispitivanja, grafici kalibracije i ispitivanja se snimaju i postaju deo izveštaja o ispitivanju.



Sl. 7. Izgled prikaza programa za automatizaciju merenja nivoa imunosti na kondukcione smetnje.

VI. ZAKLJUČAK

Ovim radom su prezentovane osnovne bitne karakteristike merenja nivoa imunosti na kondukcione smetnje naoružanja i vojne opreme. Realizovana je implementacija standarda MIL-STD-461F, CS114, u laboratoriji za EMC u TOC-u. Pokazano je da se merenja nivoa imunosti na kondukcione smetnje mogu obavljati u Faradejevom kavezu i da je moguće umesto direkcionih kaplera, kojima se monitoriše predajna snaga injekcione sonde, da se primeni varijanta sa praćenjem nivoa snage signal generatora. Takođe, prikazana je praktična realizacija automatizovanog mernog mesta za merenje nivoa imunosti na kondukcione smetnje.

U daljem radu je potrebno na osnovu ovih rezultata pokrenuti postupak za izmenu standarda odbrane Republike Srbije SORS 1029/89 i SORS 1762/89, čime bi se oni revidirali i pratili trend svetskih standarda iz te oblasti.

ABSTRACT

Conducted susceptibility is the significant feature for the most of the weapons and military equipment. Requirements and methods for measuring the immunity level are defined by domestic military standards SORS 1029/89 and SORS 1762/89, respectively and there is necessary to modernize in accordance with current international standards in this field. The requirements and methods of domestic military standards for measuring for immunity level to conducted disturbances in the laboratory for the EMC measurements of Technical Test Center have been harmonized to the MIL-STD-461F standard. The measurement methods have been adapted to the available measuring laboratory's equipment. In this paper, the development of an automatization of measurement for immunity level to conducted disturbances will be gradually shown, through a special review of the following phases: calibration and testing.

Automatization of Measurement for Immunity Level to Conducted Disturbances

Linearizacija NTC termistora dvostepenim deo-po-deo linearnim A/D konvertorom kompaktnog dizajna

Jelena Jovanović, Dragan Denić

***Apstrakt*— U ovom radu predstavljen je kompaktan dizajn dvostepenog deo-po-deo linearnog A/D konvertora koji je primenjen za linearizaciju NTC termistora. Preciznije, ovim A/D konvertorom linearizuje se napon na izlazu serijsko-paralelnog razdelnika napona koji sadrži NTC termistor. Kompaktnost ovog konvertora se odnosi na upotrebu manjeg broja komparatora, što za posledicu ima smanjenje dimenzija kola i manju potrošnju energije. Kompaktnost se postiže time što oba stepena konverzije obavlja jedan isti fleš A/D konvertor sa dve različite lestvičaste mreže otpornika, svaka upotrebljena za po jedan stepen konverzije. Dakle, ovaj dvostepeni A/D konvertor ima istu rezoluciju u oba stepena konverzije. Kompenzacija nelinearnosti pomenutog napona se vrši u prvom stepenu konverzije na taj način što je prenosna funkcija prvog stepena deo-po-deo linearna aproksimacija funkcije koja je inverzna zavisnosti izlaznog napona razdelnika od temperature. Nakon primene predloženog 16-bitnog konvertora za linearizaciju termistora oznake NTSD0XV103FE1B0, proizvođača Murata, na opsegu od -40°C do 120°C nelinearnost je iznosila 0.0022%.**

***Ključne reči*— linearizacija; NTC termistor; dvostepeni deo-po-deo linearni A/D konvertor; kompaktnost dizajna; energetska efikasnost.**

I. UVOD

NTC termistor je temperaturno osetljivi otpornik sa negativnim temperaturnim koeficijentom i veoma izraženom nelinearnošću statičke prenosne funkcije (zavisnost otpornosti termistora od merene temperature je nelinearna i monotono opadajuća funkcija) [1]. U cilju dobijanja informacije o merenoj temperaturi u digitalnom formatu, potrebno je obezbediti električni signal (napon, struja) proporcionalan merenoj temperaturi. Iz pomenutog razloga, termistor se uvek postavlja u električno kolo sa konstantnim naponskim ili strujnim izvorom. Najčešće je to serijski ili serijsko-paralelni razdelnik napona [2]. Napon na izlazu ovakvog električnog kola zavisi, po nekom nelinearnom zakonu, od merene temperature jer i otpornost NTC termistora ima nelinearnu zavisnost od merene temperature. Linearizacija nelinearne zavisnosti pomenutog napona od merene temperature je problem sa kojim se autori bave u ovom radu. Kao rezultat rada na rešavanju ovog problema nastao je veliki broj metoda linearizacije, a sa njima i mogućnost da se odabere najpodesniji metod za određenu primenu.

Postoji niz tehnika linearizacije termistora koje se obavljaju pre A/D konverzije (analogne tehnike), kao i niz digitalnih tehnika linearizacije koje se obavljaju nakon A/D konverzije (primena mikrokontrolera i look-up tabela). Primera radi, u prvu grupu mogu se svrstati tehnike koje se baziraju na primeni naponskih razdelnika, poput Vitstonovog mosta i serijsko-paralelnog otpornog razdelnika napona [2], zatim kombinaciji serijsko-paralelnog razdelnika napona i operacionog pojačavača [3]. Interesantan primer predstavlja i primena aktivnog analognog kola koje se sastoji od stabilnog DC naponskog izvora, pojačavača jediničnog pojačanja, linearizacionog otpornika vezanog na red sa NTC termistorom i invertujućeg pojačavača [4]. Pojačavač jediničnog pojačanja sadrži operacioni pojačavač kojim se umanjuje pobudni napon koji može da prouzrokuje samozagrevanje termistora. Kako je pobudni napon negativan, invertujući pojačavač na svom izlazu daje pozitivan napon. Na ovaj način, obezbeđeno je da sa porastom temperature raste i izlazni napon. Adekvatnim izborom linearizacionog otpornika može se obezbediti linearna zavisnost izlaznog napona od merene temperature. U konkretnom slučaju, nelinearnost nakon izvršene linearizacije iznosi ±1% za temperaturni opseg od 30°C do 120°C.

Analogne tehnike se često koriste, ali je nedostatak ovih tehnika to što dodatne komponente povećavaju i troškove realizacije i potrošnju energije. Takođe, vremenom se karakteristike analognih komponenti menjaju. Dodatno, kompenzaciju kros-osetljivosti senzora koji se linearizuje na različite parametre teško je izvesti samo primenom hardverskih komponenti.

U grupu digitalnih tehnika linearizacije spada primena look-up tabela. Ova tehnika linearizacije je često zastupljena u tzv. embeded mernim sistemima (Embedded Measurement Systems-EMS) u kojima se, za različite obrade signala, koriste mikrokontroleri. Problem sa ovim tehnikama ogleda se u tome što je potrebna veća memorija za smeštanje veće look-up tabele, pa se kod ovih tehnika uvek teži postizanju kompromisa između potrebnog memorijskog prostora i tačnosti merenja [5].

Međutim, vremenom su razvijene tzv. mešovite (analogno-digitalne) tehnike linearizacije senzora, koje se zasnivaju na primeni deo-po-deo linearnih A/D konvertora [6, 7]. Drugim rečima, linearizacija se izvodi simultano sa digitalizacijom rezultata merenja. Princip na kome se bazira linearizacija

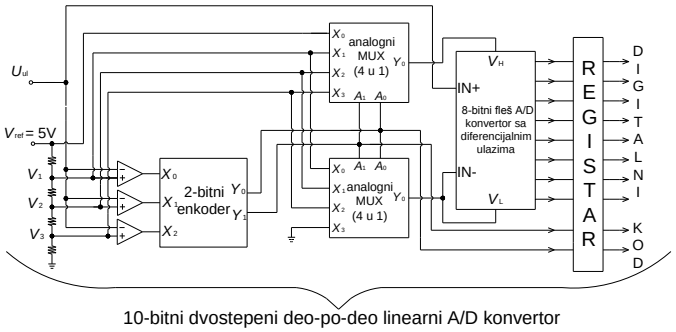
Dragan Denić – Univerzitet u Nišu, Elektronski fakultet, Aleksandra Medvedeva 14, 18000 Niš, Srbija (e-mail: dragan.denic@elfak.ni.ac.rs).



Sl. 1. Dvostepeni deo-po-deo linearni A/D konvertora sa 2-bitnim prvim stepenom, i 8-bitnim drugim stepenom konverzije, klasičnog dizajna

senzora primenom A/D konvertora je to što je statička prenosna funkcija A/D konvertora deo-po-deo linearna aproksimacija funkcije koja je inverzna funkciji koju je potrebno linearizovati. Najvažnija prednost ovih tehnika je to što se istovremeno, istim kolom, obavljaju dve različite obrade signala, čime se skraćuje ukupno vreme obrade signala. U odnosu na ostale tehnike linearizacije, troškovi realizacije celog mernog sistema i potrošnja energije su manji, a i postiže se veća kompaktnost dizajna što je naročito važno ako je potrebno realizovati sistem na čipu i sa velikim stepenom integrisanosti.

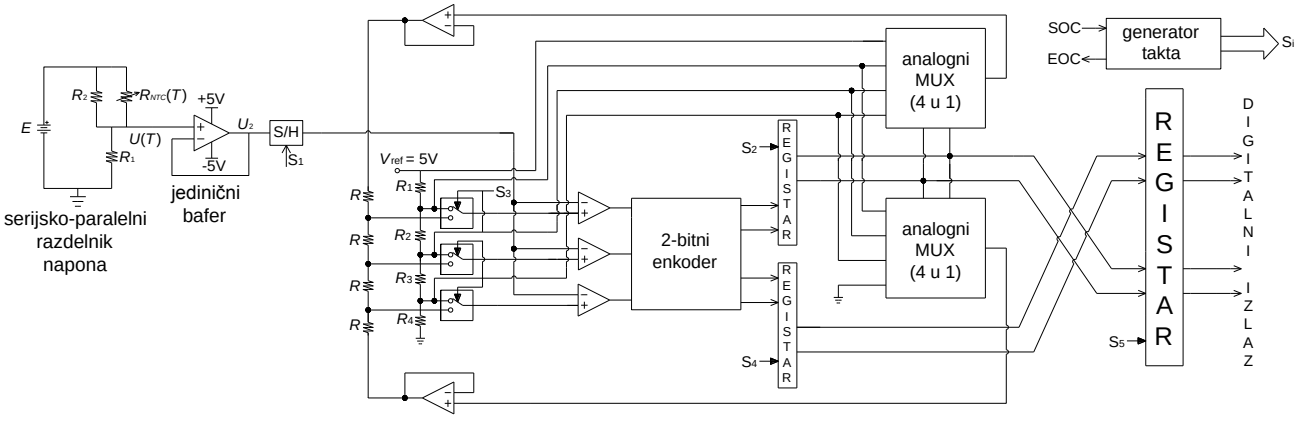
Linearizacija senzora primenom A/D konvertora obično se izvodi u dva stepena [6, 7], i to tako što se u prvom stepenu vrši kompenzacija nelinearnosti senzora, a u drugom stepenu smanjuje greška kvantizacije uneta u prvom stepenu i povećava ukupna rezolucija i preciznost merenja. Drugi stepen A/D konverzije je linearan i obično ima veću rezoluciju, za razliku od prvog koji je deo-po-deo linearan i ima manju rezoluciju (zbog kompleksnijeg dizajna). Prvi stepen konverzije obavlja fleš A/D konvertor jer je jedino u toj arhitekturi moguće izvesti deo-po-deo linearnu funkciju konverzije, dok drugi stepen može biti bilo koji tip konvertora (npr. sa sukcesivnim aproksimacijama). Još jedna velika prednost deo-po-deo linearnog A/D konvertora, u odnosu na linearni, je ta što omogućava povećanje rezolucije merenja samo u užem delu mernog opsega, čime se smanjuje prosečan broj bita za kodovanje odmeraka [6]. Primer jednog takvog A/D konvertora dat je na Sl. 1.

I pored brojnih prednosti na strani dvostepenog deo-po-deo linearnog A/D konvertora, ostaje prostora za njegovo unapređenje, pre svega u smislu jednostavnosti i kompaktnosti dizajna. U ovom radu autori primenjuju kompaktan dizajn dvostepenog deo-po-deo linearnog A/D konvertora čija oba stepena imaju istu rezoluciju, jer ih izvodi jedan fleš A/D konvertor sa dve različite lestvičaste mreže otpornika. Više o samom dizajnu i primeni ovog A/D konvertora u linearizaciji NTC termistora biće u narednom poglavlju rada.

II. KOMPAKTAN DIZAJN DVOSTEPENOG DEO-PO-DEO LINEARNOG A/D KONVERTORA

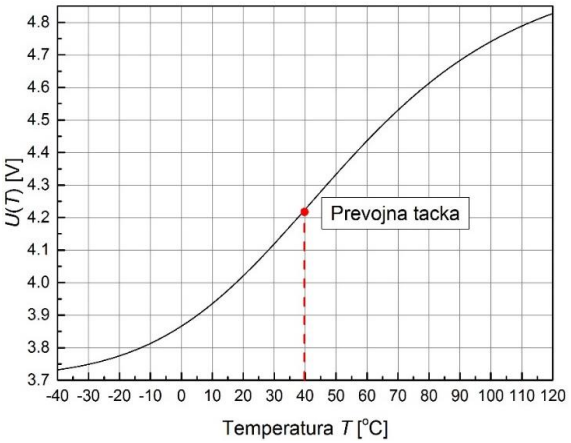
U ovom radu autori predlažu da se linearizacija NTC termistora, koji je deo serijsko-paralelnog razdelnika napona sa konstatnim naponskim izvorom, izvrši linearizacijom izlaznog napona razdelnika u dvostepenom deo-po-deo linearnom A/D konvertoru kompaktnog dizajna. Električna šema predloženog kola data je na Sl. 2. Kolo dvostepenog deo-po-deo linearnog A/D konvertora predstavlja kompaktnu verziju konvertora koju su autori koristili u radu [8]. Kompaktna verzija konvertora je razvijena sa ciljem smanjenja potrošnje energije smanjenjem broja komparatora koji učestvuju u njegovoj realizaciji, jer oba stepena konverzije obavlja jedan isti fleš A/D konvertor. Poznato je da se broj komparatora koji čine fleš A/D konvertora udvostručuje sa povećanjem rezolucije za 1 bit. Ukupna rezolucija linearizacionog kola iznosi $n=2N$, gde N predstavlja rezoluciju fleš A/D konvertora.

Zavisnost otpornosti NTC termistora od temperature može se modelovati, tj. aproksimirati tro-parametarskom Steinhart-Hart jednačinom [1, 9]. Primena ovog modela zahteva određivanje tri koeficijenta (Steinhart-Hart koeficijenti A, B i C) za šta je potrebno i dovoljno imati tri kalibracione tačke, tj. parove vrednosti (otpornost termistora, temperatura). Ove podatke smo preuzeli iz kalibracione tabele koju je obezbedio proizvođač termistora koji smo linearizovali. Reč je o NTC termistoru oznake NTSD0XV103FE1B0 proizvođača Murata [10], čiji se radni opseg prostire od -40°C do 125°C. Za proračun vrednosti otpornika R_1 i R_2 serijsko-paralelnog razdelnika napona potrebni su sledeći parametri [1]:



Sl. 2. Linearizacija NTC termistora dvostepenim deo-po-deo linearnim A/D konvertorom kompaktnog dizajna

disipaciona konstanta termistora C_d (mW/°C), otpornost termistora na 40°C (temperatura izabrane prevojne tačke, koja može uzeti bilo koju vrednost iz mernog opsega), greška merenja temperature prouzrokovana samozagrevanjem NTC termistora ΔT (°C) [1, 2, 11], i temperaturna osetljivost materijala od koga je napravljen termistor β (°K) [10]. Vrednosti ovih parametra mogu se naći u specifikacionim dokumentima koje obezbeđuje proizvođač termistora. Proračunate vrednosti otpornika R_1 i R_2 iznose: R_1=14.99 kΩ i R_2=5.22 kΩ [8]. Izlazni napon $U(T)$, na otporniku R_1, je nelinearan, a njegov oblik prikazan je na Sl. 3. Nelinearnost napona $U(T)$ je naročito izražena na granicama posmatranog temperaturnog opsega, a najbolja linearnost je u okolini prevojne tačke (40°C). Izbor prevojne tačke utiče na vrednosti otpornika R_1 i R_2, odnosno promenom vrednosti ovih otpornika menja se i oblik napona $U(T)$. U ovom radu je odabrana prevojna tačka na sredini posmatranog temperaturnog opsega.



Sl. 3. Oblik nelinearnog napona $U(T)$

Linearizacija napona $U(T)$ se izvodi dvostepenim deo-po-deo linearnim A/D konvertorom čiji je dizajn [7, 12] adaptiran specijalno za njegovu linearizaciju (refererentni naponi komparatora). U kolu prikazanom na Sl. 2 u oba stepena konverzije se koristi fleš A/D konvertor rezolucije 2 bita (N=2 bita), pa je u skladu sa konvencionalnim dizajnom fleš A/D konvertora i datom rezolucijom potrebno tri komparatora [1, 13]. Odmerak nelinearnog napona $U(T)$ i referentni naponi dovode se na ulaze komparatora radi međusobnog poređenja. Referentne napone dobijamo na otpornicima čije se otpornosti međusobno razlikuju (R_1, R_2, R_3 i R_4), jer su i referentni naponi neuniformno raspoređeni između 0 i V_{ref}. Vrednosti otpornika su odabrane tako da se na ulazima komparatora mogu podesiti vrednosti referentnih napona koje odgovaraju "break" naponima (break naponi predstavljaju granice linearnih segmenata različite širine koji čine deo-po-deo linearnu prenosnu funkciju prvog stepena konverzije). U opštem slučaju, vrednosti otpornika se moraju proračunati i podesiti unapred, kako bi linearizacija prenosne funkcije nekog senzora, ili signala sa izlaza senzora, bila moguća.

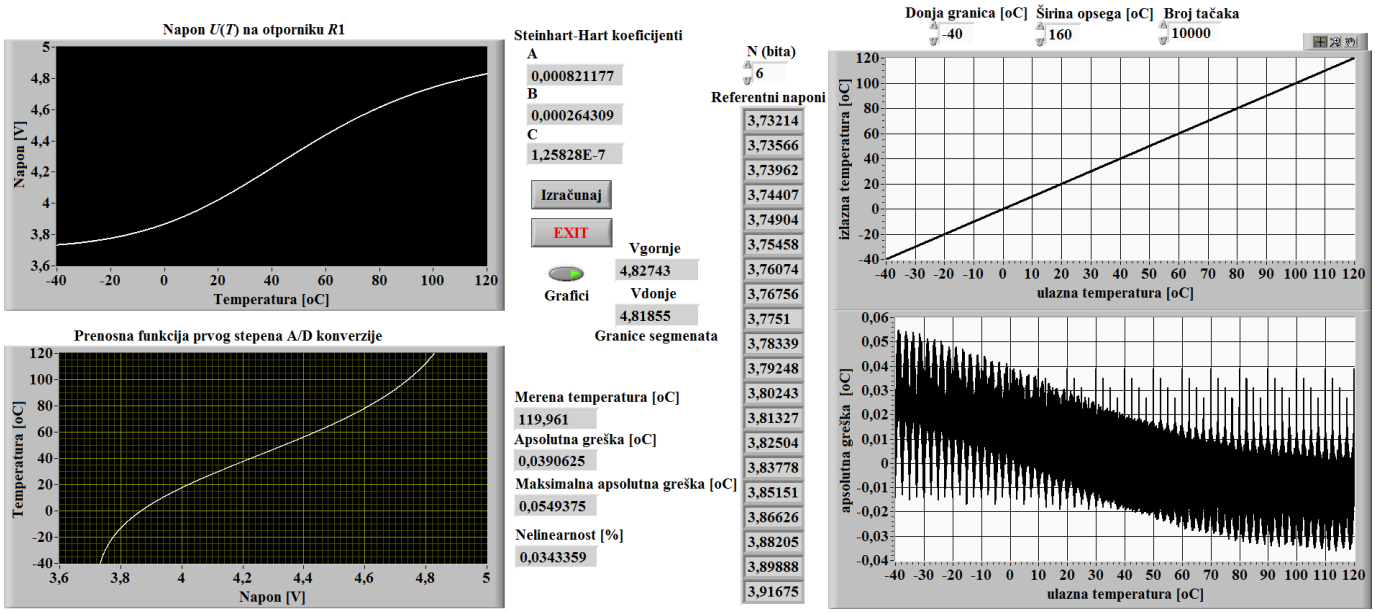
U razmatranom slučaju, signal koji se linearizuje je napon $U(T)$, pa je prenosna funkcija prvog stepena A/D konverzije deo-po-deo linearna aproksimacija njemu inverzne funkcije. Referentni naponi komparatora u prvom stepenu A/D konverzije (rezolucije 2 bita) dobijaju se tako što se temperaturni opseg podeli na 2^2=4 segmenta jednake širine (granice segmenata su T_i, i=0,1,…,2^2+1), i nađu vrednosti $U(T_k)$, k=1,…,2^2-1, pri čemu se krajnje granice temperaturnog opsega ne uzimaju u obzir (u ovom slučaju T_0 i T_5).

Rezultat prve faze konverzije su dva bita koja se smeštaju u registar primenom sinhronizacionog signala S2, a koriste se za kontrolu dva analogna multipleksera 4 u 1. Zadatak ovih multipleksera je da izdvoje granice segmenta kome pripada trenutna vrednost signala $U(T)$. U isto vreme, naponi selektovani ovim multiplekserima se vode na ulaz 2-bitnog fleš A/D konvertora sa diferencijalnim ulazima iz drugog stepena konverzije, predstavljajući granice njegovog ulaznog opsega. Sada se prekidači, kontrolisani sinhronizacionim signalom S3, zatvaraju i time zamenjuju prvu mrežu otpornika drugom mrežom, koju čine otpornici međusobno jednakih otpornosti R (jer je drugi stepen konverzije linearan). Pomenuti otpornici služe za podešavanje referentnih napona koji su uniformno raspoređeni unutar opsega definisanog referentnim, tj. "break" naponima određenim u prvom stepenu. Ovi referentni naponi se dovode na ulaze komparatora zajedno sa odmerkom napona $U(T)$. Rezultat drugog stepena konverzije predstavljaju dva bita manje težine koja se u registar smeštaju pomoću sinhronizacionog signala S4. Zajedno sa bitovima određenim u prvom stepenu konverzije, poslednja dva bita čine finalni digitalni izlaz koji ispoljava linearnu zavisnost od merene temperature.

III. NUMERIČKI REZULTATI DOBIJENI SIMULACIJOM MERNOG SISTEMA U LABVIEW SOFTVERU

Za generisanje numeričkih rezultata, koji treba da dokažu efikasnosti kola koje se predlaže za linearizaciju NTC termistora, primenjen je softverski paket LabVIEW. Na Sl. 4. je prikazan prednji panel virtuelnog instrumenta koji simulira rad celog mernog sistema uključujući kolo serijsko-paralelnog razdelnika napona i kolo 12-bitnog dvostepenog deo-po-deo linearnog A/D konvertora. Razmatran je temperaturni opseg od -40°C do 120°C.

Virtuelni instrument sadrži deo za generisanje napona $U(T)$ i njemu inverzne funkcije (deo-po-deo linearna aproksimacija ove funkcije je prenosna funkcija prvog stepena A/D konverzije). Takođe, softverski su proračunati parametri Steinhart-Hart modela termistora A, B i C, na osnovu tri poznate kalibracione tačke [1, 9]. Zatim sledi detekcija segmenta kome pripada trenutna vrednost napona $U(T)$, tj. prvi stepen A/D konverzije u kome se osim segmenta određuju i njegove granice (dva susedna referentna, tj. "break" napona). Ovi naponi predstavljaju granice ulaznog opsega drugog stepena A/D konverzije u kome se određuje uniformna ćelija kojoj pripada odmerak napona (biti manje težine). U konkretnom primeru uzeto je da oba stepena imaju rezoluciju po 6 bita, što znači da je broj neuniformnih segmenata, odnosno uniformnih ćelija 2^6-1=63.



Sl. 4. Prednji panel virtuelnog instrumenta koji simulira rad mernog sistema sa dvostepenim deo-po-deo linearnim A/D konvertorom kompaktnog dizajna

TABELA I

BROJ PRIMENJENIH KOMPARATORA U ZAVISNOSTI OD REZOLUCIJE I DIZAJNA DVOSTEPENOG DEO-PO-DEO LINEARNOG A/D KONVERTORA.

2*N* (bita)	8			12				16				
Dizajn	2x4	4+4	2+6	2x6	6+6	4+8	2+10	2x8	8+8	6+10	4+12	2+14
Broj komparatora	15	30	66	63	126	270	1026	255	510	1086	4110	16386

U realnosti, realizacija A/D konvertora ove arhitekture bila bi jako komplikovana za visoke rezolucije (tj. broj referentnih napona koje je potrebno podesiti postaje veliki), pa ni u ovom radu neće biti analizirane rezolucije veće od 8 bita po stepenu, odnosno 16 bita ukupno. Na desnoj strani prednjeg panela virtuelnog instrumenta u vidu grafika su prikazane prenosna funkcija celog mernog sistema i vrednost apsolutne greške merenja za svaku vrednost temperature (analiza je urađena sa korakom 0.016°C) unutar posmatranog opsega.

U nastavku će biti prikazani rezultati vezani za uticaj rezolucije A/D konvertora na ukupan broj komparatora, a samim tim i na energetsku efikasnost konvertora. Zaključci će biti izvedeni poređenjem predloženog, tj. kompaktnog, i klasičnog dizajna dvostepenog deo-po-deo linearnog A/D konvertora (Sl. 1), istih ukupnih rezolucija. Broj komparatora potreban za realizaciju određenog dizajna dvostepenog deo-po-deo linearnog A/D konvertora, u zavisnosti od rezolucija prvog i drugog stepena konverzije, prikazan je u Tabeli I. Razmatrani su slučajevi sa rezolucijama od 8, 12 i 16 bita. Kolone koje su u Tabeli I označene kao proizvod broja 2 i vrednosti 4, 6 ili 8 bita, odnose se na dizajn dvostepenog deo-po-deo linearnog A/D konvertora u kome jedan fleš A/D konvertor obavlja oba stepena konverzije. Ostale kolone se odnose na klasičan dizajn dvostepenog deo-po-deo linearnog A/D konvertora koji ima dva posebna fleš A/D konvertora istih ili različitih rezolucija. Posmatrajući rezultate koji su dati u Tabeli I može se zaključiti da kompaktan dizajn dvostepenog deo-po-deo linearnog A/D konvertora (2x4, 2x6 i 2x8) podrazumeva upotrebu značajno manjeg broja komparatora u poređenju sa dvostepenim deo-po-deo linearnim A/D konvertorom iste rezolucije realizovanog pomoću dva posebna fleš A/D konvertora. Nedostatak dizajna koji podrazumeva upotrebu dva posebna fleš A/D konvertora je taj što sa povećanjem rezolucije jednog fleš A/D konvertora, tako da ukupna rezolucija ostane ista (rezolucija drugog A/D konvertora je smanjena za istu vrednost), dolazi do velikog porasta u potrebnom broju komparatora (kolone 8+8, 6+10, 4+12, 2+14). Na ovaj način pokazali smo da kompaktan dizajn dvostepenog deo-po-deo linearnog A/D konvertora garantuje zauzeće manjeg prostora na integrisanoj pločici i pruža veću ekonomičnost u pogledu potrošnje energije u poređenju sa dvostepenim deo-po-deo linearnim A/D konvertorom klasičnog dizajna.

Međutim, značajnija prednost kompaktnog dizajna linearizacionog kola ogleda se u povećanju tačnosti merenja temperature. Kako bi se procenio uticaj A/D konvertora kompaktnog dizajna na tačnost merenja temperature, proračunate su vrednosti apsolutne greške merenja i nelinearnosti, primenom sledećih jednačina:

$$\Delta T(^{\circ}\mathrm{C}) = \left|T_{iz} - T_{ul}\right|, \tag{1}$$

$$\delta T(\%) = \frac{\Delta T_{\max}(^{\circ}\mathrm{C})}{\textit{širina opsega}(^{\circ}\mathrm{C})} \cdot 100\% . \tag{2}$$

TABELA II

NELINEARNOST TERMISTORA [%] NTSD0XV103FE1B0 PROIZVOĐAČA MURATA, U ZAVISNOSTI OD REZOLUCIJE DVOSTEPENOG DEO-PO-DEO LINEARNOG A/D KONVERTORA I PRIMENJENOG DIZAJNA.

	Nelinearnost δT(%)						
	Kompaktan dizajn N(bita)	Klasičan dizajn N_1(bita), N_2(bita)		Kompaktan dizajn N(bita)	Klasičan dizajn N_1(bita), N_2(bita)		
Merni opseg	$2N$=12	N_1=2, N_2=10	N_1=4, N_2=8	$2N$=16	N_1=2, N_2=14	N_1=4, N_2=12	N_1=6, N_2=10
–40°C-120°C	0.0343	4.531	0.368	0.0022	4.521	0.358	0.024
–20°C-100°C	0.0255	2.753	0.224	0.0016	2.742	0.214	0.014
0°C-80°C	0.0244	1.303	0.111	0.0015	1.291	0.101	0.007
10°C-70°C	0.0244	0.757	0.069	0.0015	0.745	0.058	0.004
20°C-60°C	0.0244	0.354	0.038	0.0015	0.343	0.027	0.002

U prethodnim izrazima figurišu sledeći parametri: T_{iz} je vrednost koja se dobija na izlazu dvostepenog deo-po-deo linearnog A/D konvertora, odnosno to je izmerena vrednost temperature, T_{ul} je vrednost na ulazu u NTC termistor, odnosno to je stvarna (tačna) vrednost temperature koja se meri, ΔT_{max} je maksimalna apsolutna greška merenja u datom opsegu merene temperature, i *širina opsega* predstavlja širinu trenutno posmatranog temperaturnog opsega. Vrednosti rezidualne nelinearnosti (nakon linearizacije) NTC termistora oznake NTSD0XV103FE1B0, proizvođača Murata, su za različite vrednosti rezolucija A/D konvertora, klasičnog i kompaktnog dizajna, prikazane u Tabeli II.

Razmatrano je više temperaturnih opsega, simetričnih u odnosu na temperaturu od 40°C. Posmatrani su slučajevi kada je ukupna rezolucija dvostepenog A/D konvertora 12, odnosno 16 bita. Iz Tabele II se jasno uočava da primena A/D konvertora kompaktnog dizajna, bez obzira na širinu mernog opsega, uvek rezultira manjom greškom nelinearnosti. Razlog za to je to što je u prvom stepenu konverzije, u kome se vrši linearizacija, velika rezoluciju (6, odnosno 8 bita), što kod dvostepenog A/D konvertora klasičnog dizajna nije uvek slučaj. Ako se zadržimo na najširi merni opseg, videćemo da se najmanja greška nelinearnosti dobija u slučaju primene 16-bitnog dvostepenog A/D konvertora kompaktnog dizajna (upotrebljeno 255 komparatora). Ova greška (0.0022%) je 10 puta manja nego u slučaju primene dvostepenog A/D konvertora klasičnog dizajna (0.024%), koji u prvom stepenu konverzije ima 6 bita i istu ukupnu rezoluciju (upotrebljeno 1086 komparatora). Ovaj rezultat je postignut zahvaljujući tome što je rezolucija prvog stepena kola kompaktnog dizajna (8 bita) veća od rezolucije prvog stepena kola klasičnog dizajna (6 bita), iako su ukupne rezolucije u oba slučaja iste (16 bita). Približno isti rezultat u okviru najšireg mernog opsega se može dobiti primenom ili 12-bitnog dvostepenog A/D konvertora kompaktnog dizajna ili 16-bitnim dvostepenim A/D konvertorom klasičnog dizajna. Dakle, u zavisnosti od željene tačnosti merenja i maksimalne rezolucije, koja je najčešće ograničena raspoloživim prostorom na integrisanoj pločici i dozvoljenom potrošnjom energije, moguće je naći kompromisno rešenje.

IV. ZAKLJUČAK

U ovom radu primenjen je kompaktan dizajn dvostepenog deo-po-deo linearnog A/D konvertora za linearizaciju NTC termistora oznake NTSD0XV103FE1B0, proizvođača Murata, na opsegu od -40°C do 120°C. NTC termistor je deo serijsko-paralelnog razdelnika napona koji na svom izlazu daje nelinearni naponski signal koji se dalje linearizuje u dvostepenom deo-po-deo linearnom A/D konvertoru. Kompaktnost ovog kola je postignuta na taj način što oba stepena konverzije obavlja jedan isti fleš A/D konvertor sa dve lestvičaste mreže otpornika: u prvom stepenu mrežu čine otpornici međusobno različitih otpornosti, dok u drugom mrežu čine otpornici međusobno jednakih otpornosti. Nakon završetka prvog stepena konverzije vrši se prebacivanje sa jedne na drugu lestvičastu mrežu otpornika. Primenom predloženog dizajna dvostepenog deo-po-deo linearnog A/D konvertora potreban broj komparatora je smanjen, pa je samim tim i potrošnja energije značajno smanjena. Takođe, i rezultati u pogledu povećanja tačnosti merenja nakon primene predloženog dvostepenog deo-po-deo linearnog A/D konvertora dokazuju njegovu efikasnost. Preciznije, greška nelinearnosti iznosi 0.0022% kada je upotrebljen dvostepeni deo-po-deo linearni A/D konvertor rezolucije 16 bita i kompaktnog dizajna (2x8), dok u slučaju primene dvostepenog deo-po-deo linearnog A/D konvertora klasičnog dizajna i iste rezolucije (6+10) nelinearnost iznosi 0.024 %, tj. 10 puta je veća. Navedeni rezultati pokazuju da se povećanje tačnosti merenja temperature, kompenzacijom nelinearnosti NTC termistora, može postići jednim energetski efikasnim, i po ceni realizacije ekonomičnim kolom.

ZAHVALNICA

Ovaj rad je podržan od strane Ministarstva prosvete, nauke i tehnološkog razvoja Republike Srbije (evidencioni broj projekta je TR 32045).

ABSTRACT

In this paper a compact design of a two-stage piecewise linear A/D converter is presented and applied for the NTC thermistor linearization. In precise, this A/D converter compensates nonlinearity of the output voltage of a serial-parallel voltage divider that is containing the NTC thermistor. The compactness of this converter refers to the implementation of a smaller number of comparators, resulting in reduction of the circuit dimensions and power consumption. Compactness is achieved by the fact that both conversion stages are performed by the same flash A/D converter with two different resistor ladder networks, each used for one conversion stage. Thus, this compact two-stage A/D converter has the same resolution in both conversion stages. The nonlinearity compensation of the previously mentioned output voltage is performed in the first conversion stage. The first conversion stage has transfer function that is piecewise linear approximation of the function inverse to dependence of the output voltage from the temperature. After employing the 16-bit two-stage A/D converter of a compact design for the linearization of the NTC thermistor NTSD0XV103FE1B0, manufactured by Murata, the achieved nonlinearity was 0.0022% in the range from -40°C to 120°C.

NTC thermistor linearization with a two-stage piecewise linear A/D converter of a compact design

Jednostavan i efikasan način za generisanje dva ansambala slučajnih brojeva uniformne raspodele sa definisanim koeficijentom korelacije

Đorđe Novaković, Dragan Pejić, Tatjana Grbić, Stefan Mirković, Marina Bulat, Nemanja Gazivoda

***Apstrakt*— U radu je dat prikaz jednostavne i efikasne metode za generisanje dva ansambla slučajnih brojeva uniformne raspodele sa zadatom vrednošću koeficijenta korelacije. Potreba za optimizacijom ovog problema se javlja u okviru primene Monte Karlo metode za određivanje merne nesigurnosti, u situacijama kada su uticajne veličine međusobno korelisane. S obzirom na vrlo veliki broj ponavljanja koja se zahtevaju radi što bolje ocene merne nesigurnosti primennom Monte Karlo metode, jasno je da svaka optimizacija doprinosi uštedi računarskih resursa i smanjenju trajanja simulacija.**

***Ključne reči*— Monte Karlo metoda, korelacija, slučajni brojevi, merna nesigurnost**

I. Uvod

Odavno je prihvaćeno da rezultat merenja nije broj, nego interval u kojem se nalazi stvarna vrednost merene veličine. Za određivanje ovog intervala je ranije korišćena teorija grešaka koja je davala mogućnost da se odrede sigurne granice greške (interval u kojem se sigurno nalazi stvarna vrednost), proceni sistematska greška, odredi nivo slučajnih grešaka, itd... U [1] (*Guide to the expression of Uncertainty in Measurement* - GUM) je definisan način iskazivanja intervala u kojem se nalazi stvarna vrednost merene veličine, uz odgovarajući nivo pouzdanosti (verovatnoću), uzimajući u obzir funkciju gustine raspodele uticajnih veličina. Opisani postupak je zasnovan na analizi propagacije mernih nesigurnosti uticajnih veličina.

Neka je veličina y određena formulom

$$y = f\left(x_1, x_2, ..., x_m\right). \tag{1}$$

Očigledno je da y zavisi od m veličina. U slučaju metrologije, y je veličina čiju mernu nesigurnost želimo da odredimo na osnovu mernih nesigurnosti izmerenih veličina ili mernih nesigurnosti poznatih veličina x_1, x_2,..., x_m.

Ako su uticajne veličine međusobno statistički nekorelisane, onda se merna nesigurnost u_y, određuje upotrebom izraza

$$u_y = \sqrt{\sum_{i=1}^{m}\left[\frac{\partial f}{\partial x_i}u_{x_i}\right]^2} \tag{2}$$

Parcijalni izvod $\partial f/\partial x_i$ i u_{x_i} predstavljaju koeficijent osetljivosti i mernu nesigurnost veličine x_i, respektivno.

U slučajevima kada su uticajne veličine međusobno korelisane, umesto (2) je neophodno koristiti

$$u_y = \sqrt{\sum_{i=1}^{m}\left[\frac{\partial f}{\partial x_i}u_{x_i}\right]^2 + 2\sum_{i=1}^{m-1}\sum_{j=i+1}^{m}\frac{\partial f}{\partial x_i}\frac{\partial f}{\partial x_j}u_{x_i}\cdot u_{x_j}\cdot r_{ij}} \tag{3}$$

gde oznaka r_{ij} predstavlja koeficijent korelacije između veličina x_i i x_j.

Pod pretpostavkom da indirektno merena veličina y ima normalnu raspodelu, definiše se proširena merna nesigurnost, u oznaci U_y, za faktor obuhvata 2 koja predstavlja opseg u kojem se nalazi stvarna vrednost y sa verovatnoćom od 95 %, tj.

$$U_y = 2\cdot u_y. \tag{4}$$

Da bismo odredili mernu nesigurnost primenom (3) treba da odredimo sve koeficijente osetljivosti, što kod komplikovanijih zavisnosti definisanih izrazom (1) zna biti matematički zahtevno. Takođe, potrebno je da znamo ili da procenimo koeficijente korelisanosti r_{ij}. U praksi se često zanemaruje činjenica da su neke veličine međusobno korelisane pa se do vrednosti merne nesigurnosti dolazi primenom (2).

Drugi način za određivanje merne nesigurnosti je korišćenjem Monte Karlo metode (Monte Carlo Method MCM) [2]. Ulazni parametri za MKM su funkcije gustina raspodela uticajnih veličina. Vrši se veliki broj ponavljanja (10^4 do 10^6 ili više), gde se u svakom ponavljanju na slučaj, a u skladu sa definisanom gustinom raspodele, generišu veličine x_i, pa se onda na osnovu (1) određuje odgovarajuća vrednost y. Ako želimo da odredimo proširenu mernu nesigurnost za nivo pouzdanosti 95 %, potrebno je:

a) sortirati sve dobijene rezultate veličine y

b) odbaciti najmanjih i najvećih 2.5 % populacije

c) odrediti polovinu razlike najveće i najmanje preostale vrednosti populacije.

U slučaju postojanja međusobne korelacije između pojedinih uticajnih veličina, neophodno je obezbediti slučajne veličine ne samo zahtevane gustine raspodele, nego

takve da odgovarajući koeficijenti korelacije budu jednaki procenjenim vrednostima r_{ij} u (3).

Često se vrši poređenje merne nesigurnosti određene po oba opisana postupka. Kod MKM nema nikakvih pretpostavki o obliku raspodele rezultantne veličine y i nije potrebno određivati, ponekad vrlo komplikovane, parcijalne izvode. S druge strane, za korektnu primenu MKM je neophodno obezbediti pretpostavljene raspodele i koeficijente korelacije uticajnih veličina. U nedostatku podataka oko oblika raspodele uticajne veličine, najčešće se pretpostalja uniformna raspodela. Uz ovu pretpostavku se dobijaja konzervativnija procena merne nesigurnosti, nego za većinu drugih raspodela.

II. POSTAVKA PROBLEMA

Za dve raspodele, X i Y, koeficijent korelacije, u oznaci ρ_{XY}, je definisan izrazom

$$\rho_{XY} = \frac{E(X \cdot Y) - E(X) \cdot E(Y)}{\sigma_X \cdot \sigma_Y}. \tag{5}$$

Za nekorelisane raspodele, brojilac u (5) će biti jednak nuli, te je samim tim njihov koeficijent korelacije jednak 0. Koeficijent korelacije između dve slučajne promenljive zapravo je kovarijansa između njihovih standardizovanih (normalizovanih) slučajnih promenljivih i uzima vrednosti od -1 do 1.

Neka su X i Y dve međusobno nekorelisane slučajne promenljive jedinične normalne raspodele (nulte srednje vrednosti i jedinične standardne devijacije) - $N(0,1)$. Pomoću X i Y formiramo veličinu Z

$$Z = k \cdot X + \sqrt{1-k^2} \cdot Y, \quad |k| < 1 \tag{6}$$

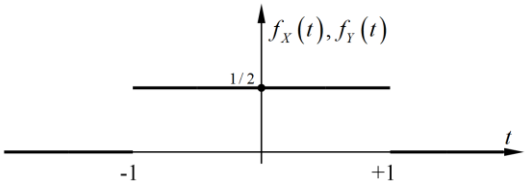
Pokazuje se da važi:

a) slučajna veličina Z ima normalnu $N(0,1)$ raspodelu,

b) koeficijent korelacije veličina X i Z će biti jednak k [3].

Autori su pokušali da primene istu metodologiju na dve veličine uniformne raspodele $U(-1,1)$.

Na slici 1. su prikazane gustine raspodele slučajnih veličina X i Y uniformne raspodele $U(-1,1)$.

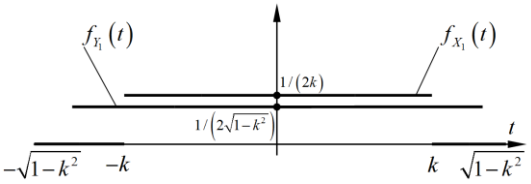


Sl. 1. Gustine raspodele veličina X i Y

Formiramo pomoćne slučajne veličine X_1 i Y_1:

$$X_1 = k \cdot X, \quad Y_1 = \sqrt{1-k^2} \cdot Y, \quad |k| < 1 \tag{7}$$

koje imaju takođe uniformne raspodele, X_1 na intervalu $(-k, k)$ i Y_1 na intervalu $\left(-\sqrt{1-k^2}, +\sqrt{1-k^2}\right)$ i njihove funkcije gustina raspodele su prikazane na slici 2.

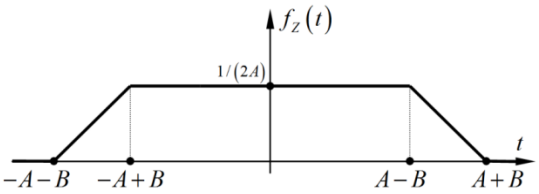


Sl. 2. Gustine raspodele veličina X_1 i Y_1

Slučajna veličina Z

$$Z = X_1 + Y_1 \tag{8}$$

ima funkciju gustine raspodele koja je prikazana na slici 3.



Sl. 3. Gustine raspodele veličine Z

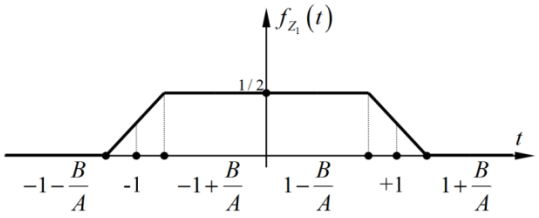
Kao u primeru sa normalnim raspodelama, dobija se da koeficijent korelacije veličine X i Z teži željenoj vrednosti k. S druge strane, kod uniformnih raspodela se dobija da rezultujuća veličina Z više nema istu gustinu raspodele kao polazne veličine X i Y. Ovde se dobija trapezna funkcija gustine raspodele. U specijalnom slučaju, kada je $k = \sqrt{1-k^2} = \sqrt{2}/2$, dobija se trougaona raspodela. Veličine A i B su određene izrazom:

$$A = \max\left(k, \sqrt{1-k^2}\right), B = \min\left(k, \sqrt{1-k^2}\right). \tag{9}$$

Za veličinu Z_1 definisanu formulom (10), prikazana je gustina raspodele na slici 4.

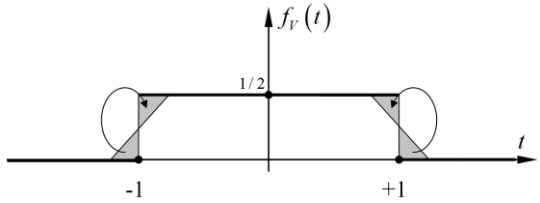
$$Z_1 = Z/A \tag{10}$$

Primetno je da se sredine bočnih strana trapezne raspodele dobijaju pri vrednostima $t = -1$, odnosno $t = +1$.



Sl. 4. Gustina raspodele veličine Z_1

Na osnovu navedenog, došli smo do ideje da polazeći od slučajne veličine Z_1, primenom geometrijskih transformacija, dobijemo slučajnu veličinu V, koja ima uniformnu $U(-1,1)$ raspodelu.



Sl. 5. Gustine raspodele veličine V

Realizacija transformacije prikazane na slici 5 se jednostavno izvodi primenom provere (11).

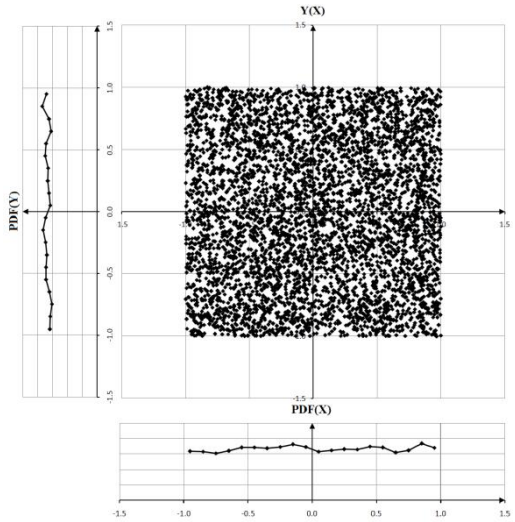
$$\begin{array}{l} \text{if } Z_1 < -1 \text{ then } V = -2 - Z_1 \\ \text{if } Z_1 > +1 \text{ then } V = +2 - Z_1 \end{array} \tag{11}$$

III. SIMULACIJE

Teorijski zaključci su potom proveravani simulacionim putem.

Dat je pseudokod Python programa koji generiše niz Z na osnovu polaznih nizova X i Y.

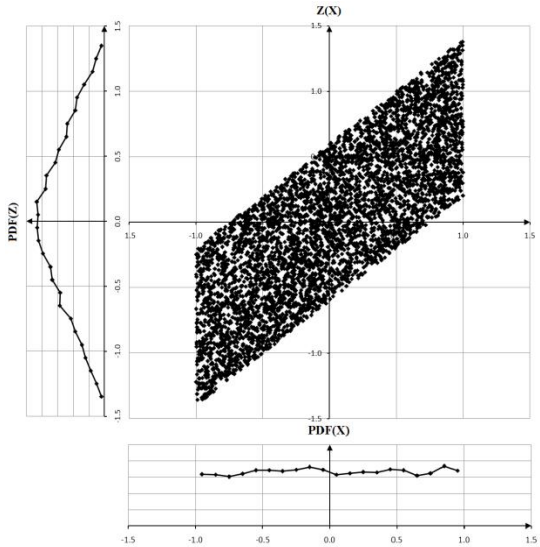
```
set k
set l to sqrt(1-k^2)
get vector_X and vector_Y from numpy.random.uniform function
set vector_V to empty array
loop through each elements in vector_X and vector_Y
   set temp_value to (k*vector_X + l*vector_Y)/max(k,l)
   if temp_value less than -1
      append (-2-temp_value) to vector_V
   else if temp_value bigger than l
      append (2-temp_value) to vector_V
   else
      append temp_value to vector_V
   end if
end loop
```



Sl. 6. *Scatter* prikaz zavisnosti *Y(X)*, prikazi histograma veličina *X* i *Y*

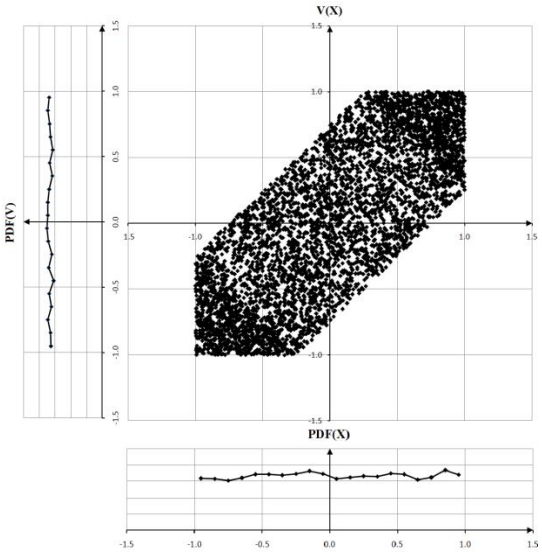
Na slikama 6, 7 i 8 su prikazane scatter zavisnosti *Y(X)*, *Z(X)* i *V(X)*, za 10000 simuliranih vrednosti, pri željenom koeficijentu korelacije 0.8, kao i dobijeni histogrami odgovarajućih veličina *X*, *Y*, *Z* i *V*.

Na slici 6 vidimo da su približno ostvarene uniformne raspodele za obe polazne veličine *X* i *Y*, a da je zbog njihove međusobne nekorelisanosti dobijeno ravnomerno pokrivanje u okviru kvadrata na grafiku *Y(X)*.



Sl. 7. Scatter prikaz zavisnosti *Z(X)*, prikazi histograma veličina *X* i *Z*

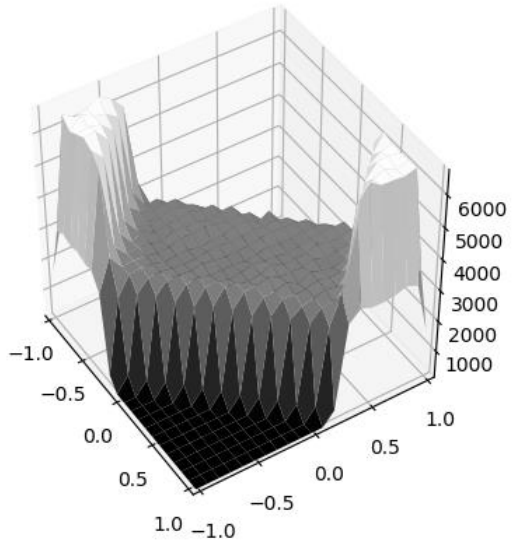
Veličina *Z*, određena na osnovu (7) ima trapeznu raspodelu, slika 7. Zavisnost *Z(X)* ima ravnomerno pokrivanje prostora, ali ne više u okviru kvadrata, nego unutar prikazanog šestougla.



Sl. 8. Scatter prikaz zavisnosti *V(X)*, prikazi histograma veličina *X* i *V*

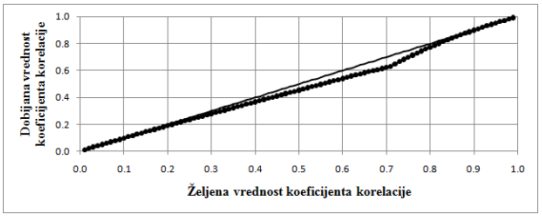
Veličina *V*, određena na osnovu (10), ima uniformu raspodelu. Na grafiku *V(X)* se uočava deo koji ima duplo veće prekrivanje, koje nastaje zbog "presavijanja" vrednosti koje su van opsega (-1,+1).

Na slici 9 je prikazan 3D histogram dobijen za milion simuliranih vrednosti *X* i *V*.



Sl. 9. 3D histogram veličina *X* i *V*

Na kraju je izvršena provera dobijenog koeficijenta korelacije ρ između *X* i *V*. Na slici 10 je prikazana zavisnost dobijenog koeficijenta korelacije ρ od željenog koeficijenta korelacije *k*, kao i prava $\rho=k$ na kojoj bi trebale da leže tačke u slučaju poklapanja ovih dveju vrednosti. Za različite vrednosti željenog koeficijenta korelacije *k* od 0 do 1, sa korakom 0.01, vršeno je ponavljanje simulacije sto puta. Na grafiku je prikazana srednja vrednost dobijenog koeficijenta korelacije ρ na osnovu vektora sa milion elemenata.



Sl. 10. Zavisnost dobijenog koeficijenta korelacije od željene vrednosti

Na slici 11 je prikazana zavisnost razlike dobijenog i željenog koeficijenta korelacije $\delta=\rho-k$. Vertikalnim stubićima je ilustrovan opseg u kojem se rasipaju rezultati.

Sl. 11. Zavisnost odstupanja dobijenog i željenog koeficijenta korelacije

Gledano očima metrologa, vidimo prisustvo slučajne i sistematske greške.

i) Slučajna greška je posledica konačnog broja elemenata i kvaliteta generatora slučajnih brojeva. Simulacije pokazuju da ova vrednost teži nuli sa povećanjem broja elemenata. Simulacije su ponavljane za tri različita generatora brojeva uniformne raspodele: Mersenne Twister, LFSR (Linear Feedback Shift Register) i kongruentnog generatora [4] [5] i nije uočena razlika u zavisnosti δ od željenog koeficijenta korelacije.

ii) Sistematska greška potiče od transformacije opisane izrazom (11). Eliminacija sistematske greške je urađena korekcijom. Neka je zavisnost dobijenog koeficijenta korelacije ρ od željenog koeficijenta korelacije k (prikazana na slici 10) data funkcijom $\rho=g(k)$. Ova funkcija nam daje vrednost koeficijenta korelacije koji ćemo dobiti ako algoritmu za generisanje dva ansambla predamo vrednost k. Inverzna funkcija nam daje vrednost koeficijenta korelacije koji treba predati algoritmu da bismo dobili baš onu vrednost koju želimo. Stoga, kada želimo da dobijemo vrednost koeficijenta korelacije ρ, algoritmu ćemo kao ulaznu veličinu proslediti $g^{-1}(\rho)$.

IV. Standardan pristup

Veličina Z, dobijena po (8) ima funkciju gustine raspodele prikazanu na slici 3. Funkcija raspodele verovatnoće veličine Z ima oblik dat u (12). Konstante navedene u (12) su pozitivne i zavise od A i B.

$$F_Z(t)=\begin{cases} 0, & t<-A-B \\ k_1\cdot t^2+k_2\cdot t+k_3, & -A-B<t\le -A+B \\ 0.5(t+1), & -A+B<t\le A-B \\ 1-k_1\cdot t^2+k_2\cdot t-k_3, & A-B<t\le A+B \\ 1, & A+B<t \end{cases} \quad (12)$$

Standardan "školski" pristup na ovom mestu bi bio primena integralne transformacije (*Probability Integral Transform* - PIT). Ovaj mehanizam se koristi za transformaciju kontinualne raspodele u uniformnu raspodelu U(0,1). Veličina K definisana izrazom (13) ima uniformnu raspodelu U(0,1).

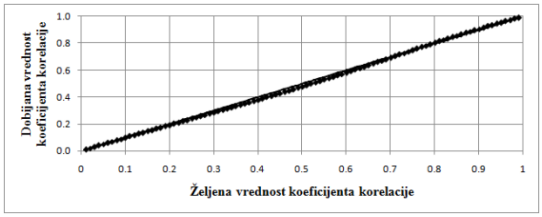
$$K=F_Z(Z), \quad K:U(0,1) \quad (13)$$

Na kraju, potrebno je veličinu K, transformisati u veličinu L primenom (14) da bi se dobila očekivana uniformna raspodela U(-1,+1).

$$L=2\cdot K-1, \quad L:U(-1,+1) \quad (14)$$

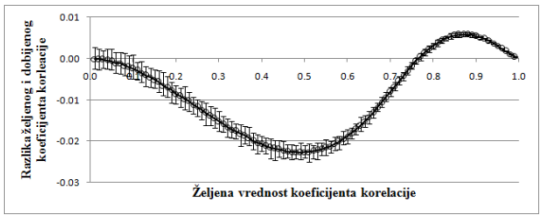
Simulacionim putem je ponovljena provera rezultata, ali ovoga puta za polaznu veličinu X i primenom PIT dobijenu veličinu L.

Na slici 12 je prikazana zavisnost dobijenog od željenog koeficijenta korelacije primenom PIT pristupa. U poređenju sa slikom 10, gde je prikazana ista zavisnost, ali za predloženu metodu, uočava se da je kod standardnog pristupa odstupanje manje.



Sl. 12. Zavisnost dobijenog koeficijenta korelacije od željene vrednosti, kada se koristi PIT

Na slici 13 prikazana zavisnost razlike dobijenog i željenog koeficijenta korelacije za standardnu PIT metodu. Sada je lakše poređenje odstupanja po predloženoj metodi (slika 11) i po standardnoj metodi (slika 13).



Sl. 13. Zavisnost odstupanja dobijenog i željenog koeficijenta korelacije, kada se koristi PIT

V. Diskusija

Prikazan je predlog nove metode za dobijanje dva ansambla uniformne raspodele i zadatog koeficijenta korelacije. Polazna osnova je postupak koji ovaj problem rešava kada je reč o jediničnim normalnim raspodelama. Prikazana je i standardna metoda za rešavanje istog problema, primenom integralne transformacije. U oba slučaja je ustanovljeno odstupanje između dobijenog i željenog koeficijenta korelacije. Kod standardne metode je ovo odstupanje oko četiri puta manje nego kod predložene metode. Vršena je provera ponašanja odstupanja dobijene i zadate vrednosti koeficijenta korelacije u zavisnosti od vrste generatora uniformnih brojeva i nije uočena nikakva zavisnost. Autori su zaključili da je odstupanje posledica transformacije trapezne raspodele uniformnom raspodelom.

Za obe metode je uočeno da je odstupanje dobijenog od željenog koeficijenta korelacije sistematska pojava. Čak i ako ne razumemo u potpunosti mehanizam delovanja sistematskog uzroka, u oba slučaja smo u stanju da otklonimo njegov uticaj. Simulacionim putem je ustanovljena zavisnost željene vrednosti ρ od zadate vrednosti k koeficijenta korelacije $\rho=g(k)$. Primenom inverzne funkcije g^{-1} je moguće izvršiti korekciju i u potpunosti otkloniti sistematsku grešku.

Po otklanjanju sistematske greške, postavlja se pitanje, koji postupak je efikasniji. Pod pojmom efikasnosti najviše se pažnja posvećuje vremenskoj efikasnosti. Primena ovog

algoritma u proračunu MKM zahteva veliki broj odbiraka čime se vreme izvršavanja MKM znatno uvećava. Ovaj algoritam bi trebao znatno ubrzati postojeće algoritme zbog svoje jednostavnosti.

VI. ZAKLJUČAK

U radu je prikazana metoda za generisanje dva ansambla uniformne raspodele sa zadatom vrednošću koeficijenta korelacije. Predloženi metod je poređen sa standardnim postupkom koji je zasnovan na primeni integralne transformacije. Standardna metoda ima četiri puta manje odstupanje dobijenog od željenog koeficijenta korelacije. Ukoliko se želi eliminisati uočeno odstupanje, u oba slučaja je neophodno vršiti korekciju, koja u potpunosti otklanja sistematsku komponentu odstupanja. Pokazano je da je predložena metoda efikasnija u smislu manjeg utroška računarskog vremena. Kod predložene metode je potrebno vršiti svega dve provere i po jedno sabiranje, dok je kod standardne metode, pored dve provere, potrebno izračunavanje transformacije koja je u dva slučaja kvadratnog tipa, a u jednom linearnog tipa. Kvadratna transformacija podrazumeva više operacija: četiri množenja i tri sabiranja, dok linearna transformacija podrazumeva po jedno sabiranje i množenje.

ZAHVALNICA

Ovaj rad je podržan od strane Ministarstva prosvete, nauke i tehnološkog razvoja Republike Srbije u sklopu projekta TR-32019, OI-174009, TR-32035.

ABSTRACT

The paper presents a simple and efficient method for generating two ensembles of random numbers of uniform distribution with the given value of the correlation coefficient. The need for optimization of this problem occurs in the application of the Monte Carlo method for the determination of measurement uncertainty, in situations where the influential quantities are correlated.

Considering the very large number of repetitions required for better estimation of uncertainty measurement by the applicable Monte Carlo method, it is clear that any optimization contributes to saving computer resources and reducing the duration of simulation.

Primena numeričkih metoda integracije na računanje efektivne vrednosti

Marina Bulat, Stefan Mirković, Dragan Pejić, Marjan Urekar, Đorđe Novaković i Nemanja Gazivoda

***Apstrakt*— Ovaj rad se bavi istraživanjem kvaliteta izračunavanja efektivne vrednosti primenom nekoliko numeričkih metoda u uslovima necelobrojnog odnosa učestanosti odmeravanja i učestanosti signala. Posmatrana su dva nezavisna problema istovremeno. Jedan je kvalitet numeričkog određivanja integrala kako bi se odredila efektivna vrednost signala, dok je drugi problem necelobrojni odnos učestanosti. Diskretizacija po amplitudi nije razmatrana.**

***Ključne reči*—odmeravanje; diskretizacija; efektivna vrednost; srednja vrednost; preciznost; trapezno pravilo; Simpsonovo pravilo.**

I. Uvod

Kod naizmeničnih napona efektivna vrednost se koristi kao osnovni parametar signala. Kvadrat efektivne vrednosti napona je srazmeran snazi koju taj napon razvija na jediničnom otporniku, pa je upravo to razlog zašto je u praksi češći slučaj da se meri efektivna vrednost nego amplituda ili trenutna vrednost napona. Stoga imamo da je

$$\frac{U_{eff}^2}{R}\cdot T=\int_0^T\frac{u^2(t)}{R}dt \qquad (1)$$

na osnovu kog se dobija analitički izraz za efektivnu vrednost napona:

$$U_{eff}=\sqrt{\frac{1}{T}\cdot\int_0^T u^2(t)\,dt}. \qquad (2)$$

Primenom analogne elektronike efektivna vrednost kontinualnog napona je određivana pomoću gore navedenog analitičkog izraza.

Pomoću analogno-digitalne konverzije analogni napon se prevodi u skup diskretnih vrednosti. Tada više nemamo na raspolaganju kontinualni signal u vremenskom domenu nego raspolažemo diskretnim skupom vrednosti. Iz ovog razloga je neophodno prilagoditi izraz za određivanje efektivne vrednosti i približno je odrediti numeričkim putem, na osnovu odbiraka koje dobijamo u procesu diskretizacije po vremenu odnosno odmeravanjem.

Ukoliko u toku jedne periode signal odmerimo u n tačaka, gde je interval integracije podeljen na n jednakih podintervala širine ΔT, uobičajeno je da se približna vrednost datog integrala proceni primenom (3):

$$U_{eff}\approx\sqrt{\frac{1}{T}\sum_{i=1}^{n}u^2(i\Delta T)\Delta T}=\sqrt{\frac{\Delta T}{T}\sum_{i=1}^{n}u^2(i\Delta T)}=\sqrt{\frac{1}{n}\sum_{i=1}^{n}u^2(i\Delta T)} \qquad (3)$$

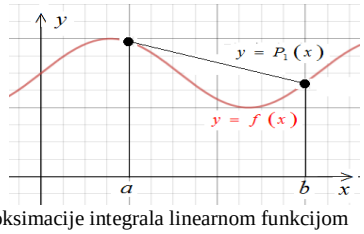
Efektivna vrednost jednaka je korenu iz srednje vrednosti kvadrata napona, pa se problem svodi na određivanje korena iz integrala kvadrata napona podeljenog sa trajanjem u kom se vrši integraljenje.

II. Numerička integracija

Numerička integracija predstavlja postupak kojim se određuje približna vrednost određenog integrala

$$I=\int_a^b f(x)\,dx,\quad a<b \qquad (4)$$

Aproksimacijom podintegralne funkcije $y=f(x)$ interpolacionim polinomom n-tog reda P_n, u zavisnosti od izbora metode.



Sl. 1. Prikaz aproksimacije integrala linearnom funkcijom

Na Sl. 1 vidimo prikaz površine određene integralom I koja je aproksimirana površinom ograničenom odsečkom funkcije $y=P_1(x)$, odsečkom ose Ox i odsečcima vertikalnih pravih u tačkama $x=a$ i $x=b$. Numeričke metode približno određuju vrednost određenog integrala tako što se data oblast podeli na što veći broj elementarnih podoblasti, koje se aproksimiraju različitim figurama, kao što su na primer pravougaonik ili trapez. Zatim se izračunaju vrednosti tih površina, a njihov zbir predstavlja aproksimaciju stvarne vrednosti određenog integrala.

A. Pravilo levih ili desnih pravougaonika

Jedna od najčešće korišćenih integracionih metoda za numeričku integraciju je pravilo levih ili desnih

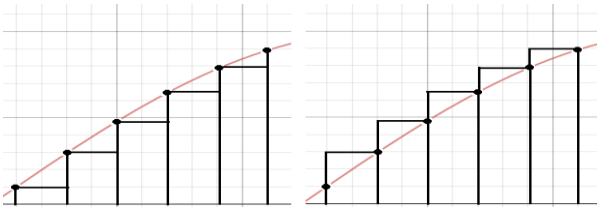
pravougaonika. Ove dve metode su grafički predstavljene na Sl. 2.



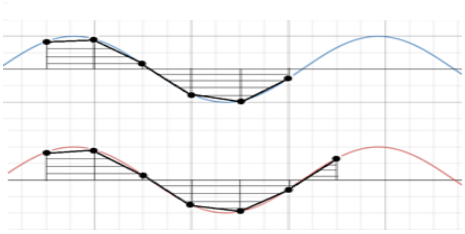
Sl. 2. Ilustracija metoda levih i desnih pravougaonika

Sa Sl. 2 se može uočiti da je uniformna dužina svih podintervala kod obe metode. Integral se aproksimira sumom površina pravougaonika gde se za jednu njegovu stranicu uzima vrednost širine podintervala ΔT, a za vrednost druge stranice pravougaonika vrednost funkcije u levoj odnosno desnoj krajnjoj tački tog podintervala. Prema ilustraciji na levoj polovini Sl. 2 možemo zaključiti da će primenom aproksimacije metodom levih pravougaonika u intervalu, gde je funkcija monotono rastuća, procena integrala biti manja od tačne vrednosti. Za opadajuću funkciju pri aproksimaciji levih pravougaonika dobili bi veću procenu integrala od stvarne vrednosti. Na desnoj polovini Sl. 2 imamo obrnutu sitaciju. Funkcija je monotono rastuća pa ćemo primenom aproksimacije desnih pravougaonika dobiti veću procenu integrala u odnosu na pravu vrednost. Ukoliko bi imali monotono opadajuću funkciju, procena integrala bi bila manja od tačne vrednosti.

1) Metoda 1

Ova metoda je standardna metoda odabiranja pravilom levih ili desnih pravougaonika koja određuje procenu efektivne vrednosti na osnovu n odbiraka dobijenih u okviru celog broja perioda, tako da su periode ograničene prolaskom napona kroz nulu, po jednačini (3).

B. Metoda 2 ili Trapezna metoda



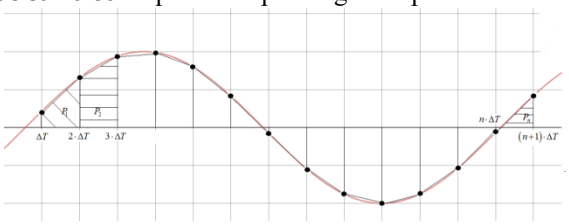
Sl. 3. Ilustracija određivanja perioda napona na osnovu prvih šest, odnosno prvih sedam tačaka

Na Sl. 3 su prikazana dva prostoperiodična napona koja su u fazi, u trajanju jedne i po periode sa istom amplitudom i učestanosti. Napon je odmeravan u šest tačaka u okviru jedne periode koja je definisana uzastopnim prolaskom rastućeg napona kroz nulti nivo. Prvih šest tačaka određuju trajanje periode koje je kraće od stvarnog trajanja periode signala. Uvođenjem sledeće, sedme tačke, dobija se opseg koji je približniji trajanju jedne periode. U zavisnosti od odnosa periode signala i periode semplovanja, perioda ograničena prvim i sedmim odbirkom će nekada biti kraća, a nekada duža od stvarne periode signala. Analize pokazuju da se dobija manja greška određivanja periode (nekada pozitivna, a nekada negativna) na osnovu sedam, nego u slučaju šest tačaka, gde se dobija veća greška uvek istog znaka (pozitivna sistematska greška).

Na Sl. 4 površina P_1 je određena donjom osnovicom ΔT, jednim krakom koji ima vrednost funkcije u trenutku odabiranja ΔT, i drugim krakom čija je vrednost funkcije u sledećem trenutku odabiranja $2\Delta T$, odnosno

$$P_1 = \frac{\Delta T}{2}\left(y(\Delta T) + y(2\Delta T)\right). \qquad (5)$$

Procena vrednosti određenog integrala I na osnovu periode koja je ograničena prvom i poslednjom, $n+1$ tačkom, računa se kao suma od n površina pravouglih trapeza.



Sl.4. Ilustracija trapezne metode

Stoga, dobijamo da je aproksimacija određenog integrala I suma od n površina definisane na datim odbircima:

$$I = \int_a^b f(x)\,dx \approx P = \sum_{i=1}^{n} P_i \qquad (6)$$

$$I \approx \frac{\Delta T}{2}\left(y(\Delta T) + y(2\Delta T)\right) + \frac{\Delta T}{2}\left(y(2\Delta T) + y(3\Delta T)\right) + \frac{\Delta T}{2}\left(y(n\Delta T) + y\left((n+1)\Delta T\right)\right)$$

$$I \approx \Delta T\left(\frac{y(\Delta T) + y\left((n+1)\cdot\Delta T\right)}{2} + \sum_{i=2}^{n} y(i\cdot\Delta T)\right). \qquad (7)$$

Ako uzmemo da je $y(i\Delta T) = y_i$, tada prethodni izraz postaje:

$$I \approx \Delta T\left(\frac{y_1 + y_{n+1}}{2} + \sum_{i=2}^{n} y_i\right). \qquad (8)$$

Na osnovu ovih proračuna pomoću izraza (3), procena efektivne vrednosti signala nad datim odbircima iznosi:

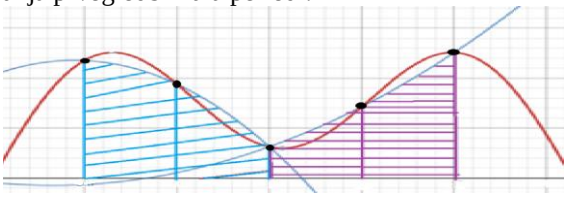
$$U_{eff} \approx \sqrt{\frac{1}{n}\left(\sum_{i=2}^{n} u_i^2 + \frac{u_1^2 + u_{n+1}^2}{2}\right)}. \qquad (9)$$

Za razliku od (3), u kojoj su svi sabirci istog značaja, u poslednjem dobijenom izrazu za efektivnu vrednost možemo uočiti da se prvi i poslednji odbirak uzimaju sa upola manjom težinom.

C. Simpsonovo pravilo

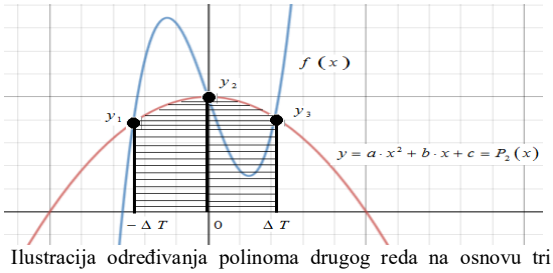
Na Sl. 5 je ilustrovana numerička integracija funkcije integracionim polinomom drugog reda. Tačna vrednost ovog integrala jednaka je površini ispod date funkcije, a približna vrednost površini ispod krive polinoma nad periodom. Simpsonovim pravilom dobija se numerička procena integrala

polinomom drugog stepena tako što se interval integracije podeli na n jednakih podintervala širine $2\Delta T$. Jedan podinterval se dobija na osnovu tri odbirka. Time je upotreba Simpsonovog pravila moguća samo u slučaja kada je broj odbiraka neparan. Ukoliko je broj dobijenih odbiraka paran, tada ova metoda ne može da se primeni. U praksi broj odbiraka dobijenih u periodi je nekad paran, a nekad neparan, što zavisi od periode signala, periode semplovanja i trenutka uzimanja prvog odbirka u periodi.



Sl. 5. Ilustracija Simpsonovog pravila

Neka je broj dobijenih odbiraka neparan u okviru jedne periode. Da bismo mogli da izvršimo procenu površine jednog podintervala, potrebno je da odredimo parabolu na osnovu tri susedne tačke funkcije. Ilustracija ovog postupka je prikazana na Sl. 6.



Sl. 6. Ilustracija određivanja polinoma drugog reda na osnovu tri tačke funkcije

$$I=\int_{-\Delta T}^{\Delta T} f(x)\,dx \approx \int_{-\Delta T}^{\Delta T} P_2(x)\,dx = \int_{-\Delta T}^{\Delta T} \left(ax^2+bx+c\right)dx = \frac{\Delta T}{3}\left(2a\Delta T^2+6c\right) \quad (10)$$

Na osnovu tačaka $(-\Delta T, y_1), (0, y_2)$ i $(\Delta T, y_3)$ dobijamo da je procena integrala nad podintervalom:

$$I \approx \frac{\Delta T}{3}\left(y_1+4y_2+y_3\right). \quad (11)$$

Na osnovu polinoma drugog reda za prve tri tačke funkcije, određuje se površina P_1, a zatim se određuje polinom drugog reda za treću, četvrtu i petu tačku, na osnovu koje se računa površina P_2. Kada se odredi površina $P_{\frac{n-1}{2}}$ na osnovu poslednje tri tačke funkcije, računa se suma svih ovih površina koja predstavlja numeričko rešenje Simpsonovog pravila. Razlika numeričkog rešenja ovog integrala i tačne vrednosti određenog integrala potiče od nepodudaranja funkcije i kvadratne aproksimacije kroz tri tačke date funkcije.

Suma površina kao aproksimacija integrala iznosi:

$$I \approx P = \sum_{i=1}^{\frac{n-1}{2}} P_i = \frac{\Delta T}{3}\left(y_1 + 4\sum_{i=1}^{\frac{n-1}{2}} y_{2\cdot i} + 2\sum_{i=1}^{\frac{n-3}{2}} y_{2\cdot i+1} + y_n\right). \quad (12)$$

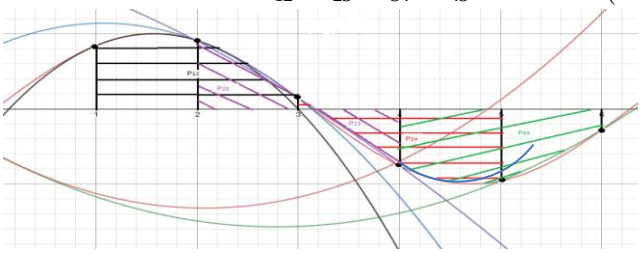
Primenjujući dalje ovaj analitički izraz u izraz za procenu efektivne vrednosti, dobijamo:

$$U_{eff} \approx \sqrt{\frac{1}{n-1}\left(\frac{u_1^2+u_n^2}{3} + \frac{4}{3}\sum_{i=1}^{\frac{n-1}{2}} u_{2\cdot i}^2 + \frac{2}{3}\sum_{i=1}^{\frac{n-3}{2}} u_{2\cdot i+1}^2\right)}. \quad (13)$$

1) Metoda 3 ili Unapređeno Simpsonovo pravilo kvadratnom funkcijom

Na Sl. 7 je prikazana ilustracija metode koja predstavlja modifikaciju Simpsonovog pravila, koju predlažu autori ovog rada. Broj semplova dobijen u okviru periode određene uzastopnim prolaskom rastućeg napona kroz nulu je šest. Jedan podinterval integracije dobija se na osnovu svake tri uzastopne tačke, na osnovu kojih se određuju polinomi drugog reda. Prvo se odredi parabola na osnovu prve, druge i treće tačke i izračuna se površina P_{12} koju ta parabola obrazuje. Zatim se na osnovu druge, treće i četvrte tačke određuje polinom drugog reda i izračuna površina P_{23}. Kada se odredi površina P_{45} na osnovu tri poslednje tačke funkcije, četvrte, pete i šeste, računa se ukupna površina kao zbir svih prethodno izračunatih površina:

$$P = P_{12} + P_{23} + P_{34} + P_{45}. \quad (14)$$



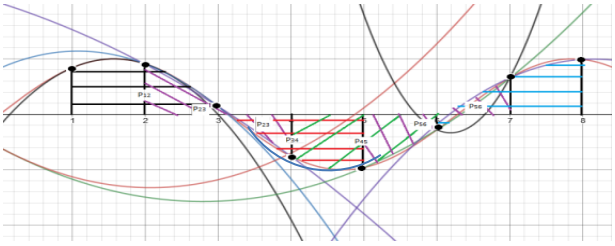
Sl.7. Ilustracija modifikacije Simpsonovog pravila

Neka su P_1 i P_2 površine, koje čine površinu P_{12}, dobijene na osnovu prve i druge odnosno druge i treće tačke i neka su P_2' i P_3 površine koje čine P_{23} dobijene na osnovu druge i treće odnosno treće i četvrte tačke. Površine P_2 i P_2' nisu jednake jer su dobijene pomoću različitih kvadratnih aproksimacija, ali su bliske po vrednostima. Ukoliko u dalji proračun uzmemo da je $P_2 \approx P_2'$, $P_3 \approx P_3'$ i $P_4 \approx P_4'$, dobijamo da aproksimacija integrala I čija je perioda određena na osnovu prve i šeste tačke postaje:

$$I \approx P = P_1 + P_2 + P_2' + P_3 + P_3' + P_4 + P_4' + P_5 \quad (15)$$

$$I \approx P_1 + 2\cdot P_2 + 2\cdot P_3 + 2\cdot P_4 + P_5 \quad (16)$$

U poslednjem izrazu možemo da uočimo da se u okviru periode dobijaju duplo veće površine P_i, osim prve i poslednje, za $i = 2, 3, 4$. Iz ovog razloga je potrebno uzeti u proračun i naredne dve tačke posle ponovnog prolaska rastućeg napona kroz nulu, tačku sedam i osam. Ilustracija ovog postupka je prikazana na Sl. 8.



Sl. 8. Ilustracija modikacije i unapređenja Simpsonovog pravila

Vrednosti funkcija u tačkama sedam i osam su bliske vrednostima funkcija u tačkama jedan i dva, pa možemo reći da su površine određene tačkom šest i sedam i tačkama sedam i osam bliske vrednostima površina P_1 i P_5.

Ukoliko prethodno uzmemo u obzir, izraz za aproksimaciju integrala I postaje:

$$I \approx P_1 + 2\cdot P_2 + 2\cdot P_3 + 2\cdot P_4 + P_5 + P_{56} + P_{67} \quad (17)$$

$$I \approx P_1 + 2\cdot P_2 + 2\cdot P_3 + 2\cdot P_4 + 2\cdot P_5 + 2\cdot P_6 + P_7 \quad (18)$$

$$P_1 \approx P_7 \quad (19)$$

$$I \approx 2\cdot\left(P_1 + P_2 + P_3 + P_4 + P_5 + P_6\right) \quad (20)$$

Na ovaj način dobijamo dva puta veću površinu od one koja nam je potrebna.

Modifikacija ove metode ogleda se u tom što se za podintervale uzimaju svake tri uzastopne tačke i u tome što je perioda ograničena prvim i drugim dodatim semplom posle ponovnog prolaska rastućeg napona kroz nulu. Parnost broja odbiraka dobijenih u okviru periode više ne igra nikakvu ulogu što predstavlja doprinos koju ova metoda daje.

Ukoliko bi za ovako definisanu periodu imali n odbiraka, tada bi površine određene na osnovu svake tri uzastopne tačke iznosile:

$$P_{12} = \frac{\Delta T}{3}\cdot\left(y_1 + 4\cdot y_2 + y_3\right) \quad (21)$$

$$P_{23} = \frac{\Delta T}{3}\cdot\left(y_2 + 4\cdot y_3 + y_4\right) \quad (22)$$

...

$$P_{n-3\,n-2} = \frac{\Delta T}{3}\cdot\left(y_{n-3} + 4\cdot y_{n-2} + y_{n-1}\right) \quad (23)$$

$$P_{n-2\,n-1} = \frac{\Delta T}{3}\cdot\left(y_{n-2} + 4\cdot y_{n-1} + y_n\right). \quad (24)$$

Primenjujući dalje ovaj analitički izraz u izraz za procenu efektivne vrednosti, dobijamo:

$$U_{eff} \approx \sqrt{\frac{1}{(n-2)}\left(\frac{u_1^2 + u_n^2}{6} + \frac{5}{6}\left(u_2^2 + u_{n-1}^2\right) + \sum_{i=3}^{n-2} u_i^2\right)}. \quad (25)$$

2) Metoda 4 ili Unapređeno Simpsonovo pravilo kubnim polinomom

Ova metoda je ekvivalent prethodnoj metodi, sa tom razlikom da su potrebna tri naredna sempla posle ponovnog prolaska rastućeg napona kroz nulu, pored semplova dobijenih u okviru jedne periode. Jedna površina se dobija na osnovu svake četiri uzastopne tačke funkcije kroz koje se aproksimira kubna funkcija. Na taj način dobija se tri puta veća površina od one površine koja je potrebna.

Da bismo mogli da izvršimo procenu površine jednog podintervala, potrebno je da odredimo kubnu funkciju na osnovu četiri tačke funkcije:

$$I = \int_{-\Delta T}^{2\cdot\Delta T} f(x)\,dx \approx \int_{-\Delta T}^{2\cdot\Delta T} P_3(x)\,dx \quad (26)$$

$$I = \int_{-\Delta T}^{\Delta T} \left(a\cdot x^3 + b\cdot x^2 + c\cdot x + d\right) dx \quad (27)$$

$$I = \frac{\Delta T}{4}\cdot\left(15\cdot a\cdot\Delta T^3 + 12\cdot b\cdot\Delta T^2 + 6\cdot c\cdot\Delta T + 12\cdot d\right). \quad (28)$$

Na osnovu tačaka $(-\Delta T, y_1), (0, y_2), (\Delta T, y_3)$ i $(2\cdot\Delta T, y_4)$ dobijamo da je procena integrala nad podintervalom:

$$I \approx \frac{3\Delta T}{8}\left(y_1 + 3y_2 + 3y_3 + y_4\right). \quad (29)$$

Na osnovu polinoma trećeg reda za prve četiri tačke funkcije, određuje se površina P_{123}, a zatim se određuje polinom trećeg reda za drugu, treću, četvrtu i petu tačku, na osnovu koje se računa površina P_{234}. Kada se odredi površina $P_{n-3\,n-2\,n-1}$ na osnovu poslednje četiri tačke funkcije, računa se suma svih ovih površina koja predstavlja numeričko rešenje ove modifikacije Simpsonovog pravila.

$$P_{123} = \frac{3\Delta T}{8}\left(y_1 + 3y_2 + 3y_3 + y_4\right) \quad (30)$$

$$P_{234} = \frac{3\Delta T}{8}\left(y_2 + 3y_3 + 3y_4 + y_5\right) \quad (31)$$

...

$$P_{n-3\,n-2\,n-1} = \frac{3\Delta T}{8}\left(y_{n-3} + 3y_{n-2} + 3y_{n-1} + y_n\right) \quad (32)$$

$$P = \frac{3\Delta T}{8}\left(y_1 + y_n + 4\left(y_2 + y_{n-1}\right) + 7\left(y_3 + y_{n-2}\right) + 8\sum_{i=4}^{n-3} y_i\right). \quad (33)$$

Primenjujući dalje ovaj analitički izraz u izraz za procenu efektivne vrednosti, dobijamo:

$$U_{eff} \approx \sqrt{\frac{1}{(n-3)}\left(\frac{u_1^2 + u_n^2}{8} + \frac{1}{2}\left(u_2^2 + u_{n-1}^2\right) + \frac{7}{8}\left(u_3^2 + u_{n-2}^2\right) + \sum_{i=4}^{n-3} u_i^2\right)}. \quad (34)$$

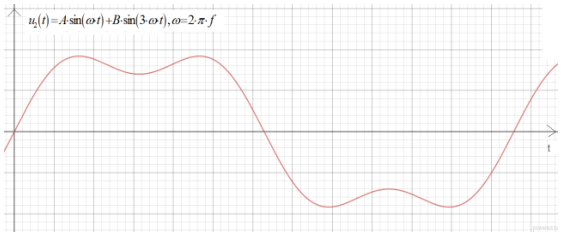
Naredne četiri metode su ekvivalent prethodno definisanim metodama, samo se ovoga puta periode definišu na osnovu prolaska rastuće ivice napona kroz prethodno određenu efektivnu vrednost napona, u čemu je doprinos ovog rada. Autori predlažu da se prvo odredi efektivna vrednost napona na osnovu prolazaka kroz nulu, a onda se nad istim odbircima izvrši računanje nove efektivne vrednosti, ali nad periodom koja je određena prolaskom napona kroz predhodno određenu efektivnu vrednost.

III. REZULTATI SIMULACIJA

Putem simulacija je proveren kvalitet numeričkog određivanja integrala kako bi se odredila efektivna vrednost

signala i uticaj necelobrojnog odnosa učestanosti odmeravanja i učestanosti signala.

Simulirana su dva signala. Jedan napon, u oznaci $u_1(t)$, je prostoperiodičan napon amplitude 1 V i učestanosti 50 Hz, a drugi napon je $u_2(t)$, predstavljen na Sl. 9.

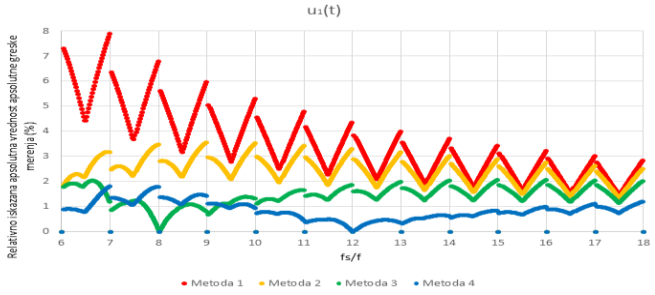


Sl. 9. Ilustracija napona $u_2(t)$

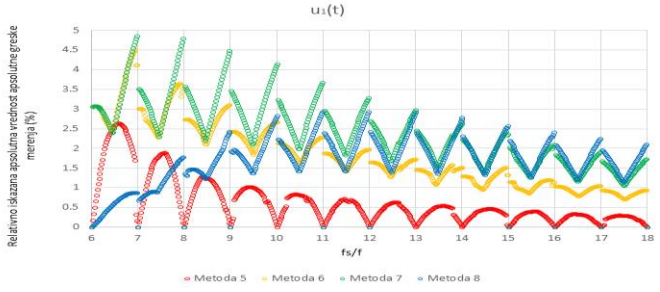
Signal $u_2(t)$ predstavlja sumu prvog i trećeg harmonika. Vrednost trećeg harmonika je odabrana tako da $u_2(t)$ prolazi kroz svoju efektivnu vrednost samo dva puta u toku jedne periode. Za veće vrednosti trećeg harmonika postojao bi problem kod određivanja periode na osnovu prolaska kroz efektivnu vrednost. U takvim slučajevima je moguće određivanje efektivne vrednosti samo primenom prve četiri metode, dok Metode 5 do 8 ne bi dale očekivani rezultat zbog pogrešnog određivanja periode signala.

U simulacijama je menjana učestanost odmeravanja sa korakom od 0.02 Hz. Ispitivano je ponašanje metoda pri odnosu učestanosti odmeravanja i učestanosti signala u granicama od 6 do 20. Da bi se verno simulirala nesinhronizovana odmeravanja, na slučajan način je uziman trenutak prvog odmeravanja gledano od početka periode signala. Greška određivanja zavisi od trenutka uzimanja prvog odbirka. Za svaku frekvenciju odmeravanja je vršeno hiljadu ponavljanja. Potom je određena najveća apsolutna vrednost greške za svaku od metoda.

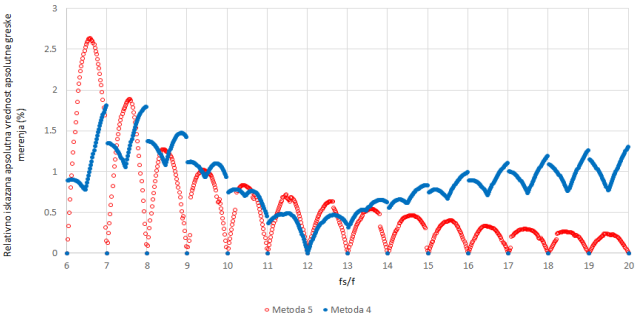
Na sledećim slikama prikazani su rezultati za oba signala za prve i druge četiri metode, respektivno, kao i rezultati poređenja metoda koje su se pokazale kao najbolje iz obe grupe.



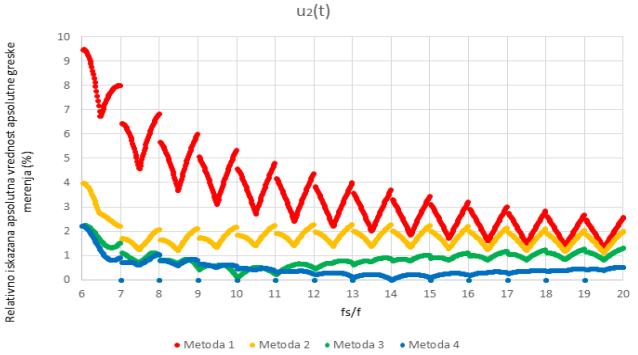
Sl. 10. Rezultati simulacije prve četiri metode za napon $u_1(t)$



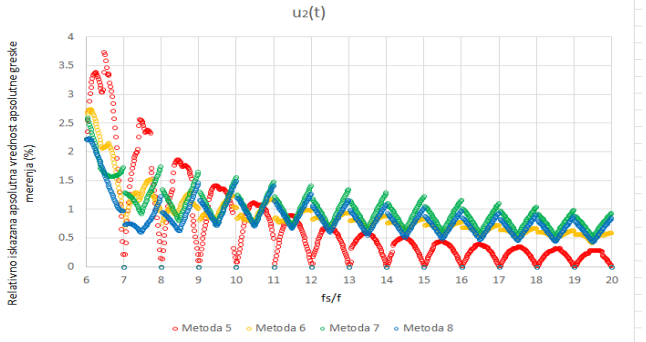
Sl. 11. Rezultati simulacije druge četiri metode za napon $u_1(t)$



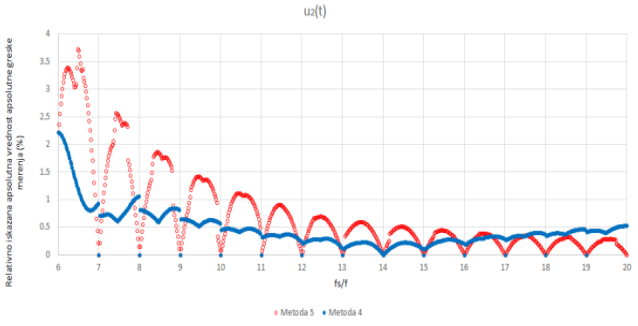
Sl. 12. Prikaz dve najbolje metode kao rezultata simulacije za napon $u_1(t)$



Sl. 13. Rezultati simulacije prve četiri metode za napon $u_2(t)$



Sl. 14. Rezultati simulacije druge četiri metode za napon $u_2(t)$



Sl. 15. Prikaz dve najbolje metode kao rezultata simulacije za napon $u_2(t)$

Sa Sl. 10 i Sl. 13 možemo da uočimo da se dobija prednost u korist svake naredne metode u odnosu na prethodnu i kod napona $u_1(t)$ i kod napona $u_2(t)$. Odnosno, kod napona kod kojih se definiše perioda uzastopnim prolaskom kroz nulu uvek se komplikovanje numeričkih metoda isplati i dobija se manja greška.

Sa Sl. 11 i Sl. 14 uočavamo obrnutu sitaciju. Komlikovanje računa za dobijanje efektivne vrednosti napona se ne isplati i vidimo da Metoda 5 ima najmanju grešku za oba signala.

Upoređivanjem dve najbolje metode iz prve i iz druge grupe serija od po četiri metode, uočavamo da je predložena Metoda 5 najefikasnija metoda kod oba napona.

IV. ZAKLJUČAK

Ovaj rad se bavi analizom metroloških osobina raznih numeričkih metoda za određivanje efektivne vrednosti napona. Cilj klasične matematike je utvrđivanje pod kojim uslovima postoji rešenje nekog problema i koje su njegove osobine, dok u numeričkoj matematici je to efektivno pronalaženje rešenja problema sa određenom tačnošću i preciznošću.

Sve formule izvedene u ovom radu imaju izraz za numeričko određivanje efektivne vrednosti koji se sastoji od korenovanja, deljenja i suma kvadrata signala pomnoženih koeficijentima, pa je vreme procesorskog rada približno jednako za sve metode.

Diskretizacija po amplitudi nije razmatrana, pa greška usled kvantizacije po vrednosti je zanemarena.

Pokazano je da se javlja problem prilikom određivanja efektivne vrednosti kada količnik učestanosti odabiranja i učestanosti ulaznog signala nije celobrojan. Zbog nesinhronog odabiranja dobija se manja efektivna vrednost kada je izvršeno više odabiranja u toku periode jer broj odbiraka u okviru jedne periode nije konstantan, već će nekad biti jedan više odbirak, a nekad jedan manje.

Urađene su simulacije za sve predložene metode. Upoređivanjem rezultata svih osam metoda, uočeno je značajno manje rasipanje rezultata i veća tačnost predložene Metode 5 u odnosu na sve ostale. U simulaciji se pokazalo da primena predložene definicije efektivne vrednosti daje tačnije i preciznije rezultate u odnosu na opštu definiciju. Kod metoda čija je perioda definisana uzastopnim prolaskom rastućeg napona kroz nulu uočena su poboljšanja ukoliko se primene druge numeričke metode u odnosu na standardnu metodu, metodu levih ili desnih pravougaonika, dok kod metoda gde je perioda ograničena uzastopnim prolaskom rastućeg napona kroz prethodno određenu efektivnu vrednost to nije slučaj. U situacijama kada se očekuje da signali imaju veliki stepen izobličenja tako da više od dva puta prolaze kroz svoju efektivnu vrednost u toku jedne periode, nije moguće primenjivati metode 5 do 8 na prikazani način. Kod ovakvih signala najbolje rezultate daje Metoda 4 – Unapređeno Simpsonovo pravilo kubnim polinomom.

Rezultati simulacija su vrlo ohrabrujući, pa bi sledeći korak provere mogućnosti predložene metode, Metode 5, mogao da bude realizovan u praksi.

ABSTRACT

This paper explores the quality of the calculation of the root mean square value using several numerical methods in the conditions of the non-integer ratio between sampling frequency and the frequency of the signal. Two independent problems were observed. One of them is the quality of the numerical assessment of integrals in order to determine root mean square. The other one is the non-integer ratio. The amplitude discretization has not been considered.

THE APPLICATION OF NUMERICAL INTEGRATION METHODS FOR DETERMINING THE ROOT MEAN SQUARE VALUE

Prilog etaloniranju termometara sa direktnim očitavanjem u terenskim uslovima

Marina Bulat, *Member, IEEE*, Nemanja Gazivoda, *Member, IEEE*, Ivan Gutai, *Member, IEEE*, Bojan Vujičić, *Member, IEEE*, Đorđe Novaković, *Member, IEEE* i Marjan Urekar, *Member, IEEE*

***Apstrakt*— U ovom radu je dat primer postupka etaloniranja termometara sa direktnim očitavanjem van Laboratorije za metrologiju Fakulteta tehničkih nauka u Novom Sadu. Prikazane su najbolje mogućnosti merenja, opisana je priprema za merenje i navedena je merna oprema koja je korišćena. Opisani su postupci merenja koji treba da se sprovedu i prikazana je obrada dobijenih rezultata. Dati su primeri koji ilustruju primenu ovog uputstva. Svi termini i definicije su u skladu sa SRPS ISO/IEC 9000:2001, SRPS ISO/IEC 17025:2017 i Međunarodnim rečnikom osnovnih i opštih termina u metrologiji.**

***Ključne reči*—** merna oprema; etaloniranje; metrologija; termometar; merna nesigurnost.

I. Uvod

Uređaji za merenje temperature ili temperaturnog gradijenta nazivaju se termometri. Međusobno se razlikuju kako po principu na kojem se zasniva njihov rad, tako i prema mernom području. Proces etaloniranja koji prethodi izdavanju uverenja o etaloniranju je u upotrebi u industriji, laboratorijama, ocenjivanju usaglašenosti tela i preduzećima, kako bi zadovoljili zahteve standarda. Uverenje o etaloniranju je sredstvo kojim se obezbeđuje dokaz sledivosti merenja.

U Tabeli I su prikazane merne mogućnosti etaloniranja termometara sa direktnim očitavanjem, raspoloživom opremom Laboratorije za metrologiju Fakulteta tehničkih nauka u Novom Sadu (u daljem tekstu samo Laboratorija), van Laboratorije.

TABELA I
NAJBOLJE MOGUĆNOSTI ETALONIRANJA VAN LABORATORIJE

Predmet etaloniranja	Temperaturni opseg	Merna nesigurnost
Otpornički termometri, termometri sa termoparom	0 °C	0.06 °C
Otpornički termometri, termometri sa termoparom	25 °C do 300 °C	0.25 °C
Otpornički termometri, termometri sa termoparom	300 °C do 650 °C	3.0 °C
Termometri sa termoparom	650 °C do 1000 °C	7.5 °C

II. Priprema za rad

Priprema za etaloniranje podrazumeva proveru metroloških karakteristika etalonskog sistema pre odlaska na mesto etaloniranja, prevoz do mesta etaloniranja, vizuelni pregled objekta etaloniranja, konstataciju da je objekt pripremljen za etaloniranje i proveru referentnih uslova etaloniranja.

Da bi se smanjili rizici tokom prenošenja opreme do i od mesta etaloniranja, pre i posle prenosa vrši se provera osnovnih metroloških karakteristika etalona. Po pravilu se oprema za etaloniranje do i od mesta etaloniranja prenosi putničkim automobilom. Obezbeđuje se da temperatura prostora u kome se nalazi oprema bude u intervalu 15 °C do 30 °C.

Za etaloniranja van Laboratorije je potrebno da objekt etaloniranja i etalonska oprema budu u prostoru namenjenom za etaloniranje najmanje jedan sat pre početka etaloniranja, da bi se njihova temperatura približno izjednačila sa temperaturom okoline.

Vizuelnim pregledom se utvrđuje opšte stanje objekta etaloniranja i konstatuju se eventualna oštećenja. Utvrđuje se i postojanje dokumentacije o objektu etaloniranja, relevantne za etaloniranje.

Za etaloniranje van Laboratorije proverava se i opšte stanje prostora u kome treba da se obavi etaloniranje, a to je da prostor mora biti suv i čist, bez prašine i drugih agensa koji mogu da utiču na mernu opremu, i da se u njemu ne odvijaju

druge aktivnosti koje mogu nepovoljno da utiču na postupak etaloniranja.

Referentni uslovi za merenje van Laboratorije su:

1. Temperatura okoline: 15 °C do 30 °C,
2. Relativna vlažnost vazduha: 30% do 70%.

Provera referentnih uslova podrazumeva ispunjenje navedenih zahteva neposredno pre merenja.

III. Merna oprema

Oprema, koja je neophodna za etaloniranje termometara sa direktnim očitavanjem, navedena je u Tabeli II.

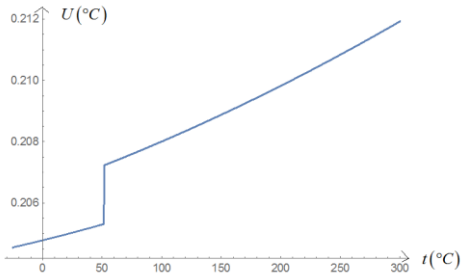
TABELA II
RADNI ETALONI ZA ETALONIRANJE TERMOMETARA SA DIREKTNIM OČITAVANJEM

Naziv	Tip	Serijski broj
Platinski otporni termometar	884X-RTD	812889
Platinski otpornički termometar	5626	812889
Etalonski termopar	S	T1-1361/1
Digitalni multimetar	8846 A 8846 A 8846 A	9310023 2090013 1918024
Kalibrator za realizaciju 0 °C	9101	B3A878
Kalibrator temperature	9103	B3A078
Kalibrator temperature	9140	B3A303
Kalibrator temperature	9141	B3A657
Kalibrator temperature	Pegasus 1200	34389/1

Imajući u vidu metrološke karakteristike etalona i svojstva zona etaloniranja, grafički su predstavljene najbolje mogućnosti etaloniranja u funkciji temperature etaloniranja i u zavisnosti od izbora etalonskog sistema.

A. – 25 °C *do* 300 °C

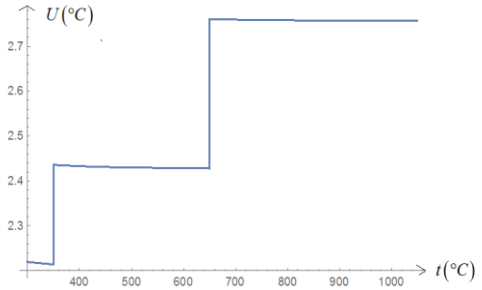
Etalonski sistem, prikazan na Sl. 1, sastoji se iz platinskog otporničkog termometra Fluke 884X-RTD i digitalnog multimetra Fluke 8846A. Za temperature etaloniranja u granicama - 25 °C do 140 °C sredina etaloniranja je suvo kupatilo Hart 9103, dok za temperature u granicama 140 °C do 300 °C sredina etaloniranja je suvo kupatilo Hart 9140.



Sl. 1. Proširena merna nesigurnost etaloniranja za faktor obuhvata $k = 2$ u zavisnosti od temperature, za etalonski sistem koji se sastoji od platinskog otporničkog termometra Fluke 884X-RTD i digitalnog multimetra Fluke 8846A

B. 300 °C *do* 1064 °C

Etalonski sistem, prikazan na Sl. 2, sastoji se iz termopara S tipa i digitalnog multimetra Fluke 8846A. Za temperature etaloniranja u granicama 300 °C do 350 °C sredina etaloniranja je suvo kupatilo Hart 9140, za temperature etaloniranja u granicama 350 °C do 650 °C sredina etaloniranja je suvo kupatilo Hart 9141, dok za temperature etaloniranja u granicama 650 °C do 1064 °C sredina etaloniranja je suvo kupatilo Pegasus 1200.



Sl. 2. Proširena merna nesigurnost etaloniranja za faktor obuhvata $k = 2$ u zavisnosti od temperature, za etalonski sistem koji se sastoji od termopara (Termotehna T1) i digitalnog multimetra Fluke 8846A

C. 1064 °C *do* 1200 °C

Za temperature etaloniranja u ovim granicama etalon je suvo kupatilo Pegasus 1200. Proširena merna nesigurnost etaloniranja je ocenjena na 3.5 °C.

Etaloniranje termometara vrši se metodom poređenja. Očitavanja na etaloniranom termometru porede se sa očitavanjima na etalonskom termometru.

IV. Etaloni

Laboratorija raspolaže opremom kojom je moguće realizovati u osnovi tri međusobno različita etalonska merna sistema. Više o njima nalazi se u nastavku rada.

A. Etalonski sistem sa otporničkom sondom i digitalnim multimetrom

Odstupanje (greška) pokazivanja rezultata merenja temperature etaloniranog termometra (DUT *engl. Device Under Test*) od temperature koju pokazuje etalonski merni sistem sa PRT sondom, modeluje se izrazom:

$$E_{DUT}=(T_{DUT}+\delta T_{DUT})-$$
$$-\left(T\left(R_s+\delta R_s+k_{Rs}+k_{Tamb}\right)+k_{PRT}+k_{DriftPRT}+k_{Stab}+k_{HomR}+k_{HomA}\right)$$

gde je:

T_{DUT} Aritmetička sredina pokazivanja DUT; Analitički izraz za njenu nesigurnost je $u_{T_{DUT}}=\frac{S_{T\,DUT}}{\sqrt{n_{T\,DUT}}}$;

$S_{T\,DUT}$ Standardno odstupanje niza pojedinačnih očitanja DUT, a $n_{T\,DUT}$ broj tih očitanja;

δT_{DUT} Korekcija očitanja DUT, zbog konačne rezolucije očitavanja. Ocena korekcije je 0 °C. Standardna nesigurnost korekcije očitanja određena je izrazom $u_{\delta T\,DUT}=\frac{LSD}{2\sqrt{3}}$, gde je *LSD* rezolucija displeja DUT;

R_s Otpornost etalonske sonde, PRT, izmerene etalonskim merilom otpornosti;

$T(R_s)$ Temperatura etaloniranja (aritmetička sredina niza očitanja), kao funkcija otpornosti R_s, definisana standardom, ili od strane proizvođača PRT, ili iz odgovarajućeg uverenja o etaloniranju. Njena nesigurnost je $u_{T(R_s)}=\frac{S_{Rs}}{\sqrt{n_{Rs}}}$, gde je S_{Rs} standardno odstupanje niza pojedinačnih očitanja R_s, a n_{Rs} broj tih očitanja;

δR_s Korekcija očitanja otpornosti R_s, zbog konačne rezolucije očitavanja;

k_{Rs} Korekcija merenja otpornosti R_s, zbog netačnosti merenja otpornosti. Ocena korekcije se preuzima iz uverenja o etaloniranju merila otpornosti. Nesigurnost korekcije preuzima se iz uverenja o etaloniranju ili se koriste podaci o tačnosti merila otpornosti, datih od strane proizvođača;

k_{Tamb} Korekcija merenja otpornosti R_s, zbog ambijentalne temperature van temperaturnog opsega digitalnog multimetra;

k_{PRT} Korekcija merenja temperature etaloniranja, zbog netačnosti PRT. Nesigurnost korekcije se preuzima iz uverenja o etaloniranju ili se koriste podaci o tačnosti merila otpornosti, datih od strane proizvođača;

$k_{DriftPRT}$ Korekcija merenja temperature etaloniranja, zbog drifta PRT;

k_{Stab} Korekcija merenja temperature etaloniranja, zbog nestabilnosti temperature etaloniranja tokom vremena etaloniranja;

k_{HomR} Korekcija merenja temperature etaloniranja, zbog radijalne nehomogenosti temperature u zoni etaloniranja;

k_{HomA} Korekcija merenja temperature etaloniranja, zbog aksijalne nehomogenosti temperature u zoni etaloniranja.

Analiza merne nesigurnosti rezultata etaloniranja DUT (merila temperature sa direktnim očitavanjem), kada se etalon sastoji od otporničke sonde (PRT) i digitalnog multimetra, prikazana je u primerima u obliku budžeta merne nesigurnosti.

Primer 1.

Etaloniran je digitalni termometar sa rezolucijom 0.1 °C na temperaturi – 20 °C. T_{DUT} je srednja vrednost od pet uzastopnih očitanja DUT. Etalonski merni sistem se sastoji od PRT (Fluke, 884X-RTD, 100 Ω, granice greške ± 0.05 °C) i digitalnog multimetra (8846 A, opseg 100 Ω, rezolucija 100 μΩ, tačnost ± (100 ppm od izmerene vrednosti + 40 ppm od mernog opsega)). R_s je srednja vrednost od pet uzastopnih očitanja etalonskog merila otpornosti. Sredina je suvi kalibrator temperature 9103 (nestabilnost temperature etaloniranja tokom vremena je 0.02 °C, radijalna nehomogenost 0.1 °C i aksijalna nehomogenost 0.1 °C). Termometar je etaloniran pri ambijentalnoj temperaturi od 15 °C. Prikaz budžeta merne nesigurnosti rezultata etaloniranja prikazan je u Tabeli III. Greška DUT je 0.1 °C, kombinovana merna nesigurnost rezultata etaloniranja 0.11 °C, a proširena merna nesigurnost za faktor obuhvata $k = 2$ rezultata etaloniranja 0.22 °C.

TABELA III
PRIKAZ BUDŽETA MERNE NESIGURNOSTI ETALONIRANJA TERMOMETRA IZ PRIMERA 1

B. *Etalonski sistem sa termoparom i digitalnim multimetrom*

Greška e_{DUT} termometra koji se etalonira (DUT) modeluje se izrazom:

$$e_{DUT}=(T_{m\,DUT}+\delta T_{DUT})-$$
$$\left(T_s(k_{ess}+\delta e_S+k_{es}+k_{Tamb})+k_{TP}+k_{DriftTP}+k_{Stab}+k_{HomR}+k_{HomA}\right)$$

gde je:

$T_{m\,DUT}$ Rezultat (aritmetička sredina) merenja temperature DUT;

δT_{DUT} Korekcija merenja temperature DUT, zbog konačne rezolucije očitavanja;

T_s Temperatura etaloniranja, kao funkcija elektromotorne sile etalonskog termopara;

k_{ess} Korekcija očitanja elektromotorne sile e_S, zbog rasipanja rezultata merenja elektromotorne sile etalonskog termopara;

δe_S Korekcija očitanja elektromotorne sile e_S, zbog konačne rezolucije očitavanja elektromotorne sile etalonskog termopara;

k_{es} Korekcija merenja elektromotorne sile e_S, zbog netačnosti merenja elektromotorne sile etalonskog termopara. Ocena korekcije se preuzima iz uverenja o etaloniranju merila elektromotorne sile. Nesigurnost korekcije se preuzima iz uverenja o etaloniranju ili se koriste podaci o tačnosti merila elektromotorne sile, datih od strane proizvođača;

k_{Tamb} Korekcija merenja otpornosti e_S, zbog ambijentalne temperature van temperaturnog opsega digitalnog multimetra;

k_{TP} Korekcija merenja temperature etaloniranja, zbog netačnosti etalonskog termopara (TP). Nesigurnost korekcije se preuzima iz uverenja o etaloniranju ili se koriste podaci o tačnosti etalonskog termopara, datih od strane proizvođača;

$k_{DriftTP}$ Korekcija merenja temperature etaloniranja, zbog drifta etalonskog termopara;

k_{Stab} Korekcija merenja temperature etaloniranja, zbog nestabilnosti temperature etaloniranja tokom vremena etaloniranja;

k_{HomR} Korekcija merenja temperature etaloniranja, zbog radijalne nehomogenosti temperature u zoni etaloniranja;

k_{HomA} Korekcija merenja temperature etaloniranja, zbog aksijalne nehomogenosti temperature u zoni etaloniranja.

C. *Kalibratori temperature*

Greška e_{DUT} termometra koji se etalonira (DUT) modeluje se izrazom:

$$e_{DUT}=(T_{m\,DUT}+\delta T_{DUT})-(T_s+k_{T_s}+k_{Stab}+k_{HomR}+k_{HomA})$$

gde je:

$T_{m\,DUT}$ Rezultat (aritmetička sredina) merenja temperature DUT;

δT_{DUT} Korekcija merenja temperature DUT, zbog konačne rezolucije očitavanja;

T_s Temperatura etaloniranja (pokazivanje kalibratora temperature);

k_{Ts} Korekcija zadate temperature etaloniranja, zbog netačnosti kalibratora temperature. Nesigurnost korekcije se preuzima iz uverenja o etaloniranju ili se koriste podaci o tačnosti kalibratora, datih od strane proizvođača;

k_{Stab} Korekcija merenja temperature etaloniranja, zbog nestabilnosti temperature etaloniranja tokom vremena etaloniranja;

k_{HomR} Korekcija merenja temperature etaloniranja, zbog radijalne nehomogenosti temperature u zoni etaloniranja;

k_{HomA} Korekcija merenja temperature etaloniranja, zbog aksijalne nehomogenosti temperature u zoni etaloniranja.

Analiza merne nesigurnosti rezultata etaloniranja DUT (merila temperature sa direktnim očitavanjem), kada je etalon kalibrator temperature, prikazana je u primerima u obliku budžeta merne nesigurnosti.

Primer 2.

Etaloniran je digitalni termometar sa rezolucijom 0.1 °C na temperaturi –20 °C. T_{DUT} je srednja vrednost od pet uzastopnih očitanja DUT. Etalonski merni sistem je kalibrator temperature Hart, 9103, granice greške ±0.25 °C. T_s je temperatura zadata kalibratorom. Nestabilnost temperature etaloniranja tokom vremena je 0.03 °C, radijalna nehomogenost 0.1 °C a aksijalna nehomogenost 0.1 °C. Termometar je etaloniran u Laboratoriji. Prikaz budžeta merne nesigurnosti rezultata etaloniranja prikazan je u Tabeli IV. Greška DUT je 0.20 °C , kombinovana standardna nesigurnost 0.17 °C, a proširena nesigurnost za faktor obuhvata $k = 2$ je 0.35 °C.

TABELA IV

ABSTRACT

The paper presents an example of the procedure for the calibration of direct reading thermometers outside the Laboratory. It demonstrates the optimal ways of measuring. In addition, it offers a description of the preparation for measuring and lists the measuring equipment that has been used. It also features a description of the measuring procedures that need to be applied and it shows the processing of the measurement results. It provides the examples illustrating the application of this instruction manual. All the terms and definitions meet the requirements of SRPS ISO/IEC 9000:2001, SRPS ISO/IEC 17025:2017 and follow International Vocabulary of Basic and General Terms in Metrology.

A Contribution to the Calibration of Direct Reading Thermometers outside the Laboratory

Sun and Displays: Old stories and new challenges

Branko Livada, *Member, SPIE*

***Abstract*— Display sun readability is very important in the case of the "mission critical" applications as avionic cockpit in harsh illumination environment, causing a lot of research and development leading to suitable, but expensive solutions. Wide display applications in mobile systems and vehicles require new cheap display solutions that should be readable in less demanding illumination conditions. Basic physical processes related to display readability are reviewed. The basic differences in display avionic and new mobile and vehicular applications are discussed. New application require still serious, but allow different approach and different technological solutions and measurement techniques.**

***Index Terms*— Displays, display readability, sun illumination, sun readability, automotive displays**

I. Introduction

An unbelievable "futuristic" idea about video phone from the beginning of the 20th century initiated a lot of research and developments in the various areas to become real nowadays. The advances in the digital image sensors, digital displays and mobile technology make it possible.

Digital information display technology development is diversified through different technical solutions [1]-[3], but no one of them provides satisfactory readability in the high illumination environment. The special and expensive ruggedization techniques should be applied to make them readable. The military and avionic application where display data are considered as mission critical initiated an extensive study and developments of the new technical solutions [4]-[9]. The mass application of the mobile devices [10] and nowadays application of the vehicle displays [11], [12], renew interest to sun readable display technology that use relatively simple and cheap technical solutions.

In this paper a short review of the up to date research leading to display sun readability and sun influence to the display functionality is presented, emphasizing physical processes involved, and related measurement techniques. The list of the selected references of the relevant work leading to deeper understanding is set [13]–[32] together with a short list of the relevant measurement standards [34]-[42]. The basic objective is to point out the importance of the sun readability in new practical applications, especially in the vehicle displays that could be considered as mission critical application. Also, new applications require new and cheaper technological solutions and new approach to measurements. Fortunately, there is nice scientific heritage regarding avionic display developments that could be used.

The basic properties of the sun irradiation and process involving sun radiation influence on display readability and display heating due to sun thermal load are presented as starting point. The basics of the display technology related to sun readability is described, followed by short review of the human visual system properties. Sun readability definition and related measurements are discussed to analyze display sun readability behavior in the harsh illumination environment.

Branko Livada is with the Vlatacom Institute, Milutina Milankovića 5, 11070 Belgrade, Serbia (e-mail: branko.livada@ vlatacom.com).

II. Sun Irradiation

The Sun is G class star with mean radius of about 695,000 km. The surface temperature is approximately 5900K by best fit blackbody curve, or about 5770K for temperature of a blackbody source that is the size and distance of the sun and would produce an exo-atmospheric total irradiance of 1390W/m2. The mean earth to sun distance is 149.680.106 km.

Typical Solar spectrum is shown in Fig. 1 [43], [44].

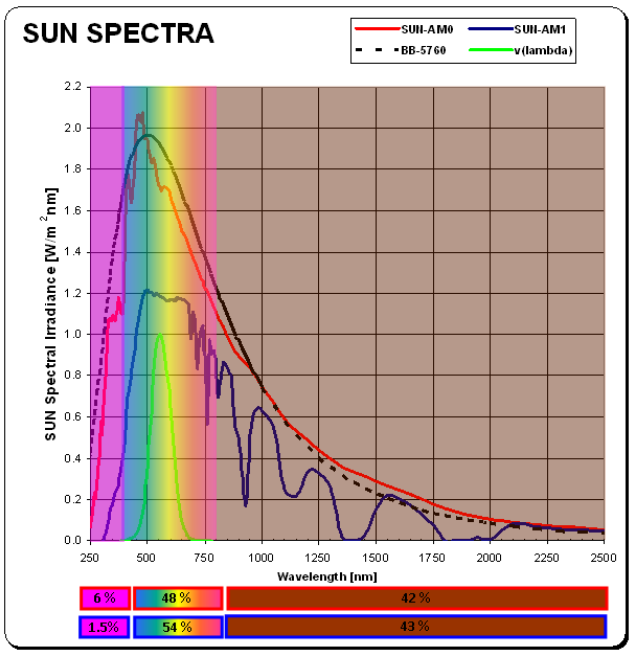

Fig. 1. Sun spectral Irradiance and spectral band flux distribution

Total solar radiation energy is distributed in different spectral regions as shown in Table I.

Mean sun irradiance outside of atmosphere is:

1390 W/m2 (mean earth-sun distance) – First Solar Constant – AM0 – Air mass zero.

As Earth trajectory is not perfect circle, Sun irradiance just outside the earth's atmosphere is:

1438 W/m2 (minimal earth-sun distance - January)
1345 W/m2 (maximal earth-sun distance - July)
Sun irradiance generates
747 W /m^2 at sea level – Second Solar Constant – AM1 – Air mass one.

Sun Illuminance outside atmosphere and on horizontal surface at sea level, maximal with sun at its zenith and clear sky is:
E = 127,823 lux = 11879 fc – Outside atmosphere
E = 86,364 lux = 8026 fc – Sea Level

TABLE I
SPECTRAL DISTRIBUTION OF SOLAR RADIATION

Spectral region (type of radiation)	Wavelength band [μm]	Relative contribution to total radiation [%]	
		Out of atm.	Sea Level
Ultraviolet - **UV**	0.29 to 0.38	**6**	**1.5**
Visible (**VIS**)	0.38 to 0.78	**48**	**54**
Near Infrared (N**IR**)	0.78 to 2.5	**42**	**43**
Far Infrared (**FIR**)	> 2.5	**4**	**1.5**

Sun irradiation influence display operation through thermal load and display image appearance (readability).

The factors influencing solar heat load thermal balance are illustrated in Fig. 2 and summarized in Table II.

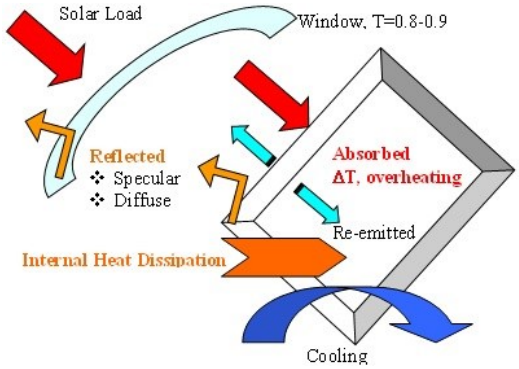

Fig. 2. Solar Load Heat balance processes

TABLE II
DISPLAY PARTS INFLUENCE ON THE THERMAL BALANCE

Display Component		Spectral Band		
		UV	***VIS***	***NIR***
External Window		A~1.0	T≅085, R=0.1	R≥0.2,
Front Glass		A~1.0	T~1.0	R≥0.2,
AMLCD		A=1.0	A≥0.7, T< 0.3	R≥0.2,
Bezel		A=1.0	A=1.0	R≥0.2,
Housing		A=1.0	A=1.0	A~1.0, E~0.9
Sun Irradiation	**OUT**	**0.06**	**0.48**	**0.42**
	SEA	**0.015**	**0.54**	**0.43**

A - Absorption; T – transmission; R - reflection

Display IR emission is comparable with solar load, and contributes to radiative cooling. The emission contribution to radiative cooling is related only to display temperature difference due to total overheating, because the part of emitted radiation is compensated from ambient. It could be considered that about 75% of solar thermal load is transferred to heat (due to solar losses in the window and NIR reflection). Radiation cooling contribution could be estimated to be about 7 W/m^2, per 1 degree K of display temperature increase.

In the case of AMLCD displays, backlight power dissipation is dominant heat source and it is the highest in high illumination conditions when high luminance level is desired.

Sun irradiation thermal load should be always considered when display is exposed to high illumination conditions. Sun related thermal load is not localized, but distributed to whole display volume. Sun load should be added to other heat sources.

There are three main types of reflection to be considered in the case of electro-optical displays [16]:
Specular reflection (surface – Fresnel's reflection) – mirror like light reflection.

Diffusive reflection (scattering and backscattering) considered as ideal Lambertian reflector – the luminance value is independent from direction

Haze reflection (organic materials – due to scattering on macromolecules) – is similar, by nature, to diffuse reflection, but spatially concentrated in selected direction, similar as specular component. Haze reflection exists between two extremes (specular and diffuse)

A more general way to describe display reflection is, so called, BRDF (Bi-Directional Reflectance Function), that involve all three (specular, diffusive and haze) components.

Display reflection or display components reflection measurements is most important part during display development phase. Also it is important part of the applied technology validation for sun readability.

Clear identification of each of three reflection types is important for display technology and structure selection for required sun readability.

Display reflection metrology should to fulfill, at least, several goals [17], [18]:

Robust: Allow some perturbations in method easing measurement process without affecting projected uncertainty.

Reproducible: Different laboratories or different operators using similar equipment should obtain same results within the requisite uncertainty.

Relevant: Must provide data comparable for different technologies and applicable in design and product improvement efforts.

Unambiguous: Must be clear for user. Method should be well documented with all relevant data on one place.

Simple: Easy and quick to perform. Avoid any un-necessary complications

Only detail BRDF measurements can to obtain full data package suitable for clear distinguishing between reflection types, but these measurements are not simple, and they are hardly applicable for fast reflection influence analysis, regarding display application and visual information extraction efficacy.

BRDF measurement results are recommended in the initial technology evaluation phase, allowing best solution selection. Because of that, several different reflection methods are developed to support sun readability evaluation.

III. Display Technology

During the second half of 20th century a lot of different display technologies were developed, as illustrated in Fig. 3.

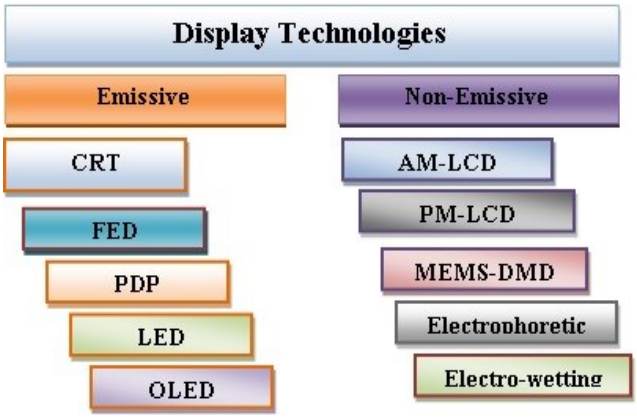

Fig.3 Display technology classification

Cathode ray tubes – CRT made a first break through in display mass application and production. Active matrix liquid crystal – AMLCD technology nowadays dominates on the market but other technologies has some advantages in selected applications (OLED - Organic Light Emitting Diode, MEMS Micro Electro Mechanical Systems). The research and development in the area of new emerging display technologies are still active.

IV. Human Visual System Basic Properties

Performance parameters of human vision are the key limiting factor for perception and extraction of information contained in the image. The visual information perception by human observer could be used directly for image quality assessment through psychophysical measurements [49]. Psychophysical measures of the image quality are too costly and time consuming for evaluation of the impact that each algorithm modification might have on image quality. On the other hand, it is convenient to have analytical model of the human vision system to be incorporated in various algorithms for image compression or processing.

The selected HVS (Human Visual System) properties describing limiting possibilities are [46]:

- Contrast sensitivity as illustrated in Fig. 4,
- Resolution power (Nyquist limit) – 56 cycles/degree,
- Visual acuity limit – 1 arc-minute, minimum perceptible limit 0.3 arc-minute,
- Dynamic Range – 10^{-6} - 10^{6} nits,
- Critical Flicker Frequency – CFF – 60 – 72 Hz.

Human visual system is adapted to be sensitive in the wide range of illumination levels - starting at less 1 mlux (night, starlight) up to more than 100 klux (direct sun illumination) for natural illumination, and up to 2klux artificial illumination (office environment).

Modeling of human vision has a long development history based on the results of psychometrics results and defined needs for aimed application. The basic principles [47], [48] are based on proper analytical modeling starting from known experimental results. One of the best known models [47] is based on the modeling of the contrast sensitivity function dependence on spatial frequency and level of illumination (see Fig. 4). Further development introduced models that involved HVS motion sensitivity (both eye motion and motion in image), temporal sensitivity and color sensitivity.

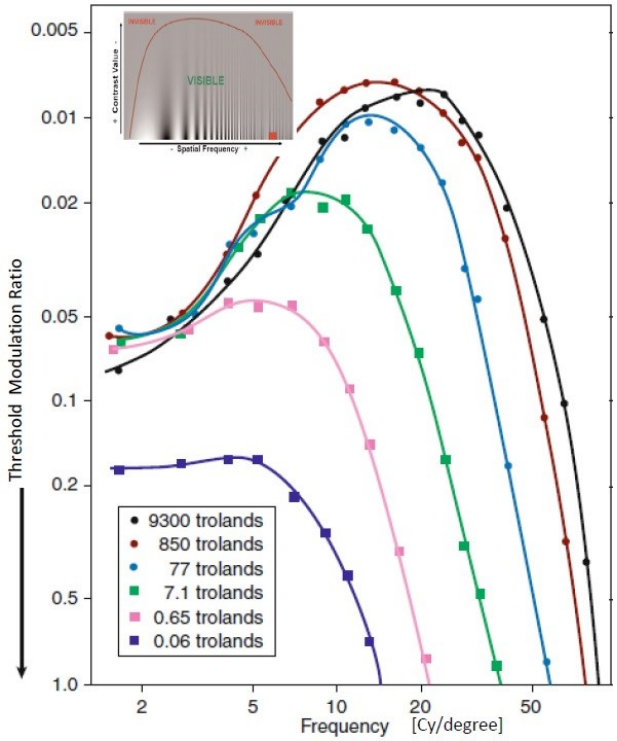

Fig. 4 HVS contrast sensitivity function (perceived threshold contrast)

V. Sun Readability

Display surface is specific light source containing information to be used by observer.

When illuminated by sun display emission is mixed with reflected sun, so information content could be severe disturbed. The root cause is reflected sun disturbance of the display visual content.

To fight sun illumination influence on the sun-readability two main approaches are used:

"Use the Sun" – Sun light illumination is used to contribute to the display luminance, as in reflective or transflective displays.

"Reject the Sun" – Techniques based on lowering reflected sun influence decreasing display reflectance, or increasing displays luminance, or both.

Sun Readability is a complex function of the whole system, in which display is used, including Display contrast and luminance, the properties of image and information content presented, the illumination environment, viewer visual properties and position.

Sun readability is mainly connected to observer's perception of visualized information. Because of that, it could be used as good display "selling point" based personal feeling as argument.

From technical point of view sun readability should be defined clearly using proper metrics and parameters that allow value understanding and repeatable measurements.

The key starting point is analysis of the display illumination environment related to system application.

The second step is definition of the display viewing envelope expected for named application.

The third, and the most important step, is defining proper sun readability metrics.

To define proper metrics required image quality and/or displayed data content, should be considered. In the case of vehicular displays the application difference between main dash-board displays and entertainment displays should be considered.

Display contrast threshold definition depending on the visual task and related illumination environment is the most common way to define sun readability criteria. This parameter is measurable, so it is fairly objective. When it is combined with display viewing and illumination conditions then we can have proper defined metrics.

Another, more accurate parameter defining sun legibility is PJND (Perceived Just Noticeable Difference) that is combined from CJND (Chrominance Just Noticeable Difference) and LJND (Luminance Just Noticeable Difference) using mathematical model to process display luminance and illumination environment spectral data following visual task requirements and observer's visual properties. Because of measurements and modeling complexity this approach is not widely accepted as legibility criteria through display specification and acceptance testing. Display complete sun readability evaluation could be complicated, and because of that, it is important to simplify measurement conditions reducing them to the worst case measurements.

Sun illumination has severe influence to display readability, including display active area sun reflections degrading display contrast (display "bleaching" or "wash out"), display chromaticity changes, and observer's eye sensitivity degradation in high direct sun illumination conditions.

System designer task is to apply all possible measures to reduce illumination (shading, windows, position selection, internal wall processing etc.) making illumination environment less severe. Also, system designer should to define display illumination environment and requirements to display design.

The large variety of illumination scenarios for sun-readable display applications is a big challenge for display system designer.

The first step is dominant source definition (direct sun, diffused – scattered illumination).

Second step is illumination source position definition related to display normal (geometry), based on illumination scenario analysis and worst case determination, applicable for test conditions definitions.

Observer eye reference points and related eye position reference boxes, defining display viewing envelope for named application is one of the possible "filters" applicable for worst case definition (see Fig. 5).

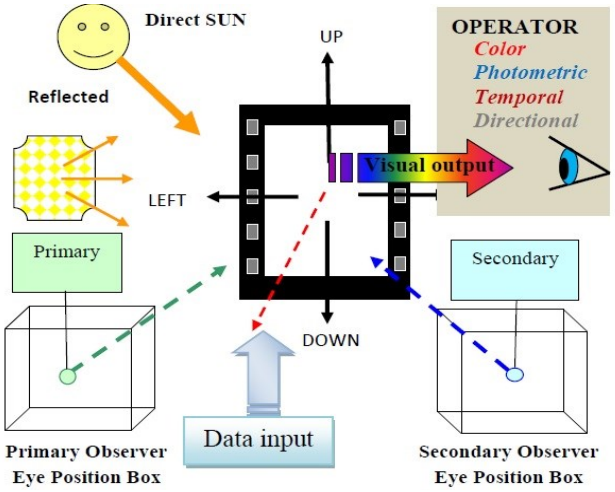

Fig. 5 Illumination environment definition

Display luminance should be in accordance with illumination scenario to allow sharp and comfortable display content perception (see illustration at Fig. 6).

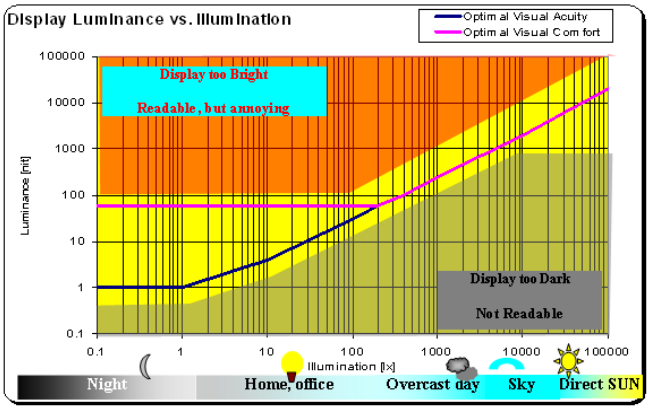

Fig. 6 Display luminance recommended level versus illumination

In the case of military or "mission critical" displays, illumination condition considered for readability evaluation, the worst illumination condition for planned application are used. Such worst illumination conditions are illustrated in Table III.

In the case of automotive displays, the key challenge is to define critical illumination conditions related to application to provide leading line for related technology development.

TABLE III
SUGGESTED VALUES FOR DISPLAY ILLUMINATION AND GLARE LUMINANCE TEST VALUES FOR AVIONIC DISPLAYS

Source Type	Sun shine ambient			
	Bubble Canopy	**Cockpit with Roof**	**Shaded**	**Enclosed cabin**
Diffusive, (Illumination)	108000 lux (10000 fc)	86000 lux (8000 fc)	3240 lux (300 fc)	540 lux (50 fc)
Specular (glare)	6800 nits (2000 fL)	6800 nits (2000 fL)	6800 nits (2000 fL)	3400 lux (1000fc)

VI. Display Measurements in Harsh Illumination Environment

Display measurements related to operation in harsh illumination environment are usually limited to display contrast measurements under simulated illumination causing specular and/or diffusive reflection.

A. *Specular Reflection* Measurements

Specular reflection (mirror like reflection) produced virtual image of the source. Specular reflection on display surface is usually connected to Fresnel reflection at boundary surface between two optically different media.

LCD Display specular reflection has higher than expected value because LCD structure is multi layered structure of glass and high index of refraction conductive ITO (Indium Tin Oxide) coatings. Haze reflection is also, higher because of light scattering on pixel patterned structure.

Practically, it is not so important to distinguish the nature of reflection because both, specular and haze reflection disturb display visual information content on the same way. There are several ways to measure specular reflection:

(A) Collimated source and narrow field of view radiation receiver: The better collimated beam and narrow as possible receiver field of view will contribute to better isolation of the haze reflection influence. This method is not widely used in display metrology.

(B) Large source specular measurements: Large uniform Lambertian source is placed under angle θs relative to display normal and narrow field of view receiver is placed at angle θr on the opposite side (see Fig. 7) and θs ≈ θr (usually 15° or 30°). The change in position size and uniformity of the source can introduce significant error. This method is excellent simulation of the real situation and it is widely used in display metrology, although do not allow clear distinguishing between specular and haze reflection. The similar case is with human eye, which count only reflected radiation in designated direction and do not recognize reflection type.

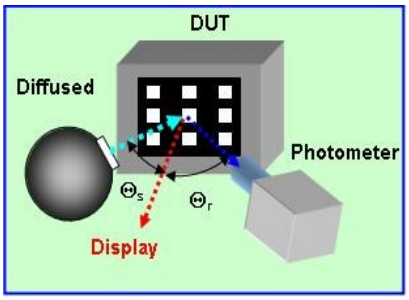

Fig. 7 Display specular reflection set up

B. *Diffusive Reflection Measurement*

In the case that concentrated - collimated incident beam (high intensity distant point source) is completely and uniformly scattered over hemisphere, one can call these type of diffuse reflection Lambertian or ideal diffuse reflection. In that case the luminance is the same in all directions.

The most common method to determine Lambertian (ideal diffuse) reflection is illustrated in Fig. 8.

Collimated beam generating predefined uniform illumination is angularly separated from receiver (low FOV photometer). The angle between incident beam direction and measurement direction is usually 30° (15°). There are two basic experimental configurations commonly used: (A) Source collimated beam optical axis is normal to display surface; (B) Photometer optical axis is normal to display surface. The incident beam illumination is determined using same experimental arrangement, but flat calibrated ideal Lambertian reflector (White reflector standard) is placed in the same plane as Display under test surface.

The display contrast measurements, under combined illumination (specular and diffusive), is illustrated Fig. 9.

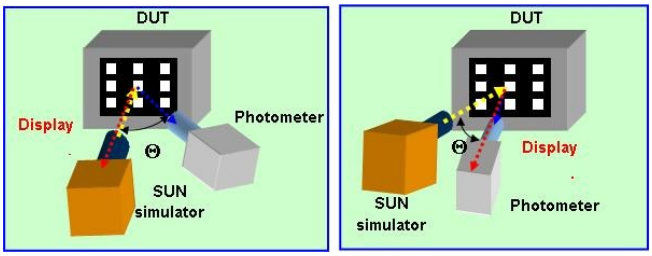

Fig. 8 Display Diffusive reflectance measurement set-up

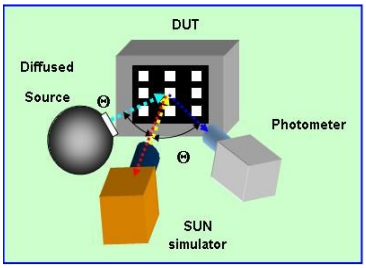

Fig. 9 Display contrast ratio measurements set- up, combined sources

VII. Conclusion

Information display mass application in mobile devices and automotive industry, require new approach to display sun readability. Sun readability was concern in "mission critical" application in avionic cockpit leading to new technical solutions according to deep knowledge of the critical processes.

Automotive display [10] applications are in the certain level mission critical (dash board displays) where sun readability is an important property. In the same time, entertainment automotive displays require good picture appearance [48], and sun readability is good "selling point".

The importance of the sun readability in the case of the automotive displays is emphasized with attention on similarities and differences with avionic displays. The scientific heritage regarding sun readability research of the avionic displays is excellent basis for new approach to sun readability measurement methods suitable for automotive displays. The basic physical processes defining sun readability are presented to support new approach on automotive displays

sun readability measurements [49] that should be based on critical illumination ambient conditions analysis. Starting from good definition of illumination environment, and display technology requirement definition, using ambient light sensors to control display operation lead to reliable and relatively cheap technical solutions.

Influence of Hydrogen Reduction on Microchannel Plate Parameters

A. Stanković, I. Zlatković, R. Nikolov, B. Brindić and D. Pantić

***Abstract*—Hydrogen reduction is a very important step in a microchannel plate (MCP) technology. This process determines the glass wafer behavior and thus defines the conductive and secondary electron emission properties. In this paper, the effect of the temperature and the time of the hydrogen reduction process on a fixed pattern noise (FPN) threshold are examined, as well as obtaining optimal resistance of MCP. In order to see the effect of reduction experiments are made with MCPs from the same batch (the same thermal history).**

***Index Terms*— Reduction, lead-silicate glasses, resistance, microchannel plate, FPN.**

I. Introduction

Microchannel plate (MCP) is a specially fabricated plate, that has several million channels and each one works as an independent electron multiplier. Fig.1 shows the MCP structure and working principle based on secondary electron emission: when incident electron enters the channel, it collides with channel inner wall surface and produces one or more electrons, that further moves down the channel by the electric field and repeatedly re-collides with channel wall, forming high-density electron cloud on output of MCP.

MCP starts as a glass tube, consisting of a core (Boron silicate- soluble glass) and cladding (lead silicate glass) that forms the microchannel structure after drawing into fibers, assembling to bundle, fusing, slicing and polishing to wafers. Next, in a chemical process, the core is removed, leaving the structure of millions of channels. The next step is hydrogen reduction in which a conducting layer is produced and a secondary electron emission layer formed on the surface of the microchannel inner wall. These surface layers can have an electron yield up to 3.5 and surface conductivity of 10^{-2} $(\Omega cm)^{-1}$ [1]. The hydrogen reduction is one of the most important processes in the technology of microchannel production where MCP gets proper electrical conductivity.

Lastly, a contact layer is evaporated to provide electrical contact. Microchannel plates are widely used as detectors of charged particles, in all types of electron microscopy and image intensifier tubs for low light level imaging as electron multipliers. [3-6]

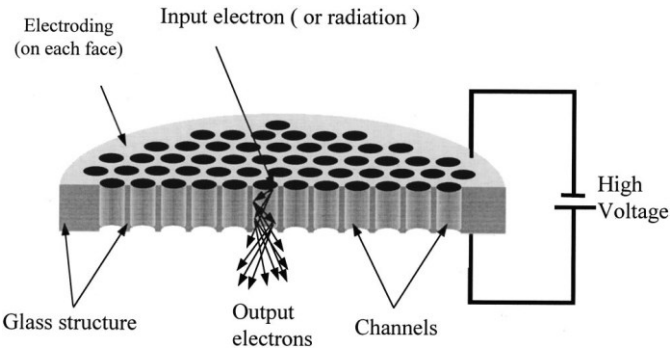

Fig.1. Structure and basic operation of MCP [2]

II. Hydrogen Reduction

Hydrogen reduction (HR) reduces the oxide of lead metal (from the surface of the glass in contact with hydrogen) and creates a thin semiconductor layer on the surface of the MCP channel. In this way, MCP activation is carried out. The electrical surface conductivity increases in several orders of magnitude in the reduction process. Generally, MCP resistance depends on the composition of the glass, the thermal history, and the reduction conditions.

The HR process is done at a given temperature in an atmosphere of hydrogen. Parameters that define the reduction process (temperature and time) depend greatly on the previous thermal processes. The thermal history of the microchannel plate begins with the first draw, and then the second. The next step in production is fusion, where interdiffusion between the core and cladding is achieved, as well as the degassing and fusion of the block at high pressure and temperature. With temperature and time of HR corrections of the desired resistance (80-200 MΩ), amplification and FPN threshold can be achieved.

Layers that are formed after reduction are [7, 8, and 9]:

1. Emission layer 20nm thick, rich in silica and alkali metals. This layer contains electrons that participate in the secondary emission of electrons.
2. A conductive layer that is rich in the lead at a depth of 100-200nm. The conductive layer function is to donate the electrons emitted by the emission layer using a strip current.

In figure 2 the cross-section of the channel wall is shown, we can see a secondary emission layer rich with silicon

dioxide and alkali metals. Alkaline elements are electropositive, which means they easily release electrons. This gives a constant source of electrons for the secondary emission of electrons. This layer determines the MCP gain.

The next layer is a conductive (resistant) layer of 50-100nm thickness. Since here lead glass is used, this layer is rich in lead. The MCP input current is of the order of 10-20 pA and the output is about 300nA (excited electrons are formed). The composition of the glass and the conditions of the reduction process (time and temperature) can control the resistance of the MCP. This resistant layer consists of a cluster (group) of lead that is used to transfer electrons. In the HR process, in the first phase, small lead grains are formed. At temperatures of 450-500°C, grains begin grouping into clusters, and the principle of conducting the current is the principle of skipping the electron from the island to adjacent islands of lead. When the electron gets out from the lattice of potassium hole remains, this place is filled with a lead electron, and then we have that second movement of current called a strip, i.e., MCP current. The most common is the output current of up to 10% of strip current. These are the electrical characteristics of the microchannel plate.

$$R = Umcp / Istrip \quad (1)$$

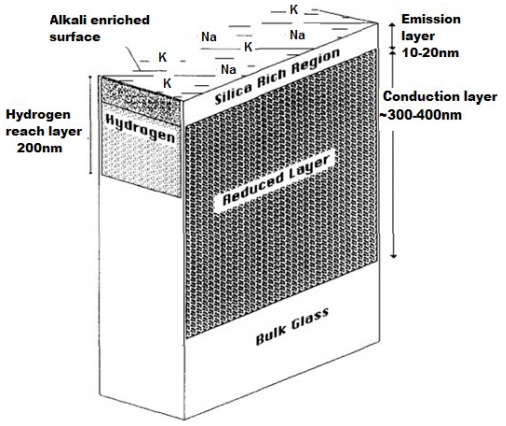

Fig. 2. MCP wall structure. [1]

On the surface of the channels, during the reduction process alkaline metal impurities (carbonates, silicates, hydrates, and chlorides) can occur due to the created conditions for the diffusion of alkaline cations to the surface through the walls. The appearance of cations on the surface is accompanied by the formation of various compounds when cations come into contact with water vapor, hydrogen, and silicates on the channel walls. They can cause excess gas, Ion feedback, and other negative effects in the work of the MCP. A thin film formed after reduction and its elimination by additional etching is shown below.

In order to achieve better results, HR is done in several stages. In the first phase, the water from the channel walls is removed, left after etching in the N_2 atmosphere.

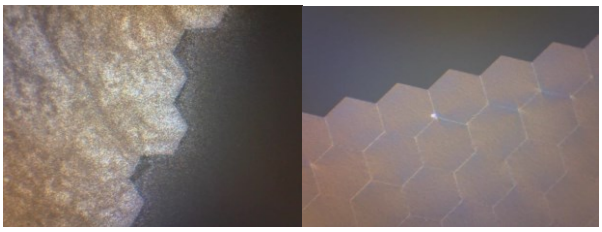

Fig. 3. Thin film layer formed after reduction (left). Removed thin film with additional etching (right).

The following stage implies the reduction of lead from the channel walls, and then the alkaline layer from the surfaces is removed by chemical treatment. The next phase is the removal of residual water (i.e. residual O2) absorbed on the surface. In the end, the formation of the conductive layer is completed, and the removal of the channel water is achieved. This improves the resistance of the MCP and the efficiency of the electron secondary emission. Cooling is performed slowly and with controlled speed to a certain temperature, followed by natural cooling. This method will improve channel purity, reduce gas content and gaseous emission, and improve the quality and reliability of the MCP.

III. Experiment

In this experiment, microchannel plates from the same block were used. Different parameters of reduction were applied. In the first case time was fixed, t=95min, while the temperature ranges between 430°C and 460°C. In the second case, the temperature is fixed, T=449°C, while the reduction time changes in the range of 35min to 155min.

In both experiments, 2-3 plates per day were used with specific reduction parameters (temperature and time) in the furnace. It is very important that the critical temperature Tg of the glass tube is not exceeded in the reduction, otherwise bending or even cracking of the microchannel plate itself can occur.

The values of the temperature and reduction time are chosen so that they are out of the optimal range, in order to create a clearer image of the consequences and characteristics of such treatment on the microchannel plate. We got either too high or too low resistance of the MCP then needed for its normal work. The second parameter that was measured is FPN threshold: it appears in the form of elements and the network. Fixed-pattern noise is usually a cosmetic blemish characterized by a faint hexagonal (honeycomb) pattern that appears throughout the viewing area. Measurements are given in tables 1 and 2, where electrical and electro-optical characteristics of the MCP are shown.

Based on good results of the first experiment related to FPN (showed in table 1) at a temperature of 449°C, the second experiment was performed with HR process at the same temperature, while reduction time was changed in the range from t = 35min to t = 155min (table 2). Figure 4 shows the dependence of the resistance and FPN threshold on the temperature and the time of reduction.

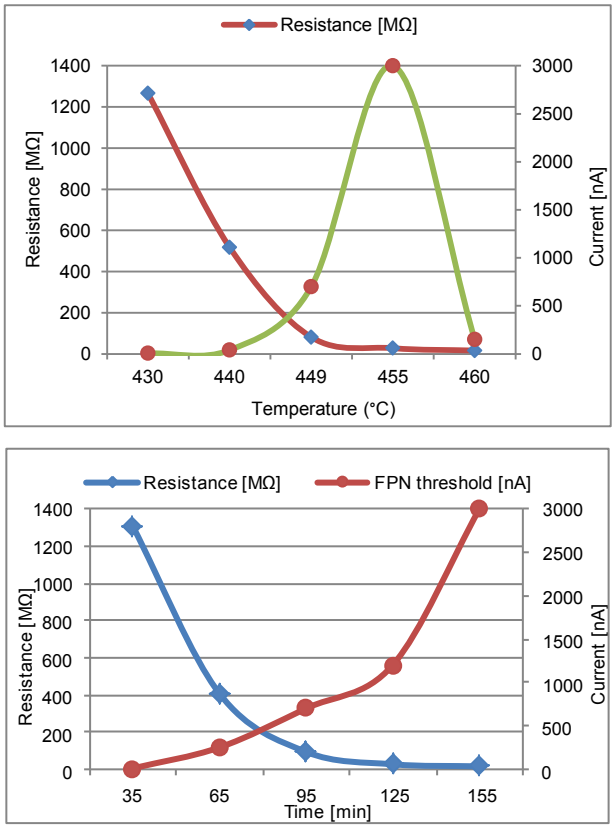

Fig. 4. Graph of resistance and FPN threshold change with the respect of reduction temperature (first graph) and time (second graph).

IV. Results and Conclusion of the Experiment

Observing experiment results of the HR process at higher temperatures, we can say that FPN disappears, i.e. it is not visible in the operating mode (U= 800V, I= 300nA), in contrary to the resistance that is too small. From graphic, we can see that for the different temperature values of 449°C and 459°C the same FPN threshold is reached, while the resistance is quite different (for 449°C, R= 92.91MΩ and 459°C is R= 18.86MΩ). When the HR temperature increases above 440ºC, the FPN threshold curve (green line) rises to a certain value and then falls. The maximum FPN threshold is at a temperature of 455°C while the resistance, R= 27.86MΩ, is outside the desired resistance value. In this experiment, we got optimal resistance and FPN threshold at the temperature of 449°C, based on that the second experiment was done where the time of reduction is changing.

The time-change experiment of the HR at constant temperature shows a clear trend of increasing the FPN threshold, with the growing time of reduction. As HR time increases, there is a significant increase in FPN threshold, it riches its maximum at 155min, but resistance gets too low.

From the above mentioned, we can conclude the following:

- When increasing the temperature and time of the reduction process, the resistance of the MCP decreases, initially significant, and then slower.
- In the initial phase of the HR process, the resistance and threshold of the FPN change simultaneously (and opposite). Intensifying the HR process by increasing the time and temperature, resistance changes gradually, while variations in the FPN threshold can be quite significant.

V. Conclusion

The reduction is a key process that is well controlled to ensure uniformity of gain and an acceptable variation between batches. The plate is reduced several times in order to produce the conductive layer beneath the surface layer. The channel surface is heated in dry hydrogen to reduce the glass-metal oxides. Production of the semi-conductive layer provides a conductive path for the electron secondary emission process. This conductive layer is one of the principal operating features of the microchannel plate. The goal of the reduction process is to create a repeatable layer throughout the channel matrix. In this paper, we examined the influence of reduction on MCP resistance and the FPN threshold. Optimal resistance and FPN threshold were obtained at a reduction temperature of 449°C and a time of 95 minutes.

Acknowledgment

We are grateful to Photon Optronics that have created conditions for performing experiments and measuring characteristics of the microchannel plate.

***Abstract*—This paper describes the design and testing of a step-up circuit for thermoelectric energy harvesting application under natural convection conditions. Considered thermoelectric generator with a suitable heatsink at a temperature difference of about $30\,^{\circ}\mathrm{C}$ provides a voltage of $60\,\mathrm{mV}$ at the load. The voltage is boosted using the Meissner oscillator and voltage doubler circuit. For the oscillator circuit, an analytical small signal model for the oscillation frequency estimation has been developed. The experimental characterization of the step-up circuit for thermoelectric energy harvesting was performed. It is shown that the voltage can be boosted up to $6\,\mathrm{V}$ DC.**

***Index Terms*—Step-up circuit, Meissner oscillator, Thermal Energy Harvesting, Natural Convection.**

I. Introduction

Due to industrial progress, the demand for energy consumption is rising exponentially. This will not only lead to the rapid depletion of the fossil fuel reserves but will also increase the problem of global warming. To reduce these problems and keep up with increasing energy demand, it is required to develop clean, efficient and sustainable energy production. Energy harvesting presents an appropriate solution for replacing batteries and power supplies for low power devices. Energy harvesting requires three separate technologies working together. Those are energy conversion, which transforms ambient energy into electrical energy, power management which boosts and regulates the generated energy, and energy storage [1]. Sources for energy harvesting are mainly solar radiation, temperature difference, pressure, kinetics, vibrations, or magnetic induction. In this paper, we will consider a thermoelectric generator (TEG) which, due to temperature difference, creates a voltage.

The voltage obtained by converting thermal energy into electrical one needs to be increased and stored so that it can be used to power some complex systems, such as wireless sensor network nodes. For this purpose, low voltage boost converter circuits for energy harvesting, based on Meissner oscillators [2], have been developed. These circuits are realized on a printed circuit board [3] or in integrated techniques [4]. Garcha et al. in [5] reported the lowest voltage integrated electrical startup system ($25\,\mathrm{mV}$) with on-chip magnetic elements. In [6], Macrelli et al. present design of step-up oscillator integrated circuit fabricated in $0.32\,\mu\mathrm{m}$ technology with two bond wire microtransformers with different cores. Simplified configuration of step up integrated circuit LTC3108 [7] is described in [8]. Some studies are about the low voltage step-up circuits for thermoelectric [9], [10], solar [11], mechanical [12], [13] or RF [14] energy harvesting.

In this paper, a low voltage step-up circuit for thermal energy harvesting will be presented. The characterization of an assembly incorporating a commercial TEG and a heatsink was performed in order to investigate the influence of the heatsink design on the value of the generated voltage. This voltage is sufficient to drive the oscillator circuit whose output voltage is further increased by a voltage doubler circuit. Obtained rectified voltage is stored in a large capacitor and it can be used for powering of other elements of the wireless sensor network node. The electric circuit of oscillator and voltage doubler was realized using discrete commercial electronic devices.

II. Thermoelectric Generator with Heatsink under Natural Convection

The temperature gradient from the environment has the potential to generate electrical power using a thermoelectric generator. This is a solid-state device whose working principle is based on the Seebeck effect. TEG is made of N thermoelectric couples consisting of n-type (containing free electrons) and p-type (containing free holes) box-shaped elements wired electrically in series and thermally arranged in parallel. When a temperature gradient (ΔT) is applied to the opposite sides of the TEG, the mobile charge carriers at the hot side diffuse to the cold side of the TEG. The buildup of charge carriers

results in a net charge at the cold side, producing the open–circuit voltage:

$$V_{TEGoc} = N\alpha\Delta T \ , \tag{1}$$

where α is Seebeck coefficient. This voltage can power an electric load through the external circuit. The commercial TEGs are usually made of doped Bi–Te semiconductor alloys having thermoelectric properties.

In our work commercial thermoelectric module GM200-127-14-16 is utilized as a generator [15]. The selected TEG has the following characteristics - dimensions: (40×40×3.4) mm, number of thermoelectric couples $N = 127$, internal electrical resistance $R_{TEG}(25\,^{\circ}\mathrm{C}) = 2.1\,\Omega$. For proper operation of the TEG the rejected heat must be removed from its cold side through a heatsink. Two types of low profile heatsinks are considered: aluminum heatsink [16] and metal (copper) foam heatsink [17]. The thermal resistance of aluminum heatsink is $9.38\,\mathrm{K/W}$, while for metal foam heatsink this value is $17.4\,\mathrm{K/W}$. The overall dimensions of both heatsinks are the same (40×40×5) mm. The aluminum heatsink has pin fin geometry, which is preferable for natural convection, while the metal foam heatsink has a form of a rectangular prism.

An aluminum heatsink is the most widely used type of heatsinks. The properties of the aluminum heatsink are excellent thermal and electrical conductivity, low weight, excellent corrosion resistance and no magnetization effect, which avoids interference of magnetic fields. The aluminum heatsink weighs approximately half as much as a copper one having the same thermal conductivity. Anodizing of the heatsink surfaces improves the strength of the natural corrosion protection.

The characteristics of the metal foam heatsink are determined by the geometry of metal foam cell structure, purity, and ductility of the metal. Low profile metal foam heatsink uses micro-porous copper foam where the interconnected pores of the foam create a large surface area. A thin hard layer of copper oxide improves the emissivity of the foam. Studies show that metal foam heatsinks offer excellent thermal performance due to their extremely high specific surface area and thermal conductivity. This is particularly important for applications which demand low volume and weight of the heatsink [18].

The mechanism of thermal energy transfer through the TEG and heatsink is conduction, while transfer of the heat from their surfaces is performed by convection and radiation. Convection is the transfer of the heat Q from a hot surface to an ambient at a lower temperature:

$$Q = h_c A(T_s - T_{amb}) \ , \tag{2}$$

where h_c is heat transfer coefficient, A is surface area, T_s is surface temperature and T_{amb} is ambient temperature. In this paper, thermal energy harvesting under natural convection conditions is considered. Natural convection is the occurrence of the air flow induced by buoyant forces. It arises from different densities of the fluid, due to the temperature variations. According to experimental research, approximately $70\,\%$ of the heat is transferred by natural convection [19]. Radiation transfers the heat between two surfaces at different temperatures in the form of electromagnetic waves.

The experimental setup, as illustrated in Fig. 1, includes cardboard box as a domain boundary, hot chuck as a heater for TEG, thermoelectric generator with heatsink and voltage step-up (boost) circuit as a device under test (DUT), oscilloscope, digital multimeter, and two PT100 temperature sensors. One PT100 sensor measures the temperature of the hot side of TEG T_{hot} and the other measures the ambient temperature. When starting the experiment, hot chuck is set to a defined temperature and appropriate voltage values are measured continuously. The voltages generated by the TEG and oscillator, as well as the output voltage are acquired by digital multimeter Agilent 34410A and through a digital oscilloscope Tektronix DPO4034. A photograph of the experimental setup located inside the domain is given in Fig. 2.

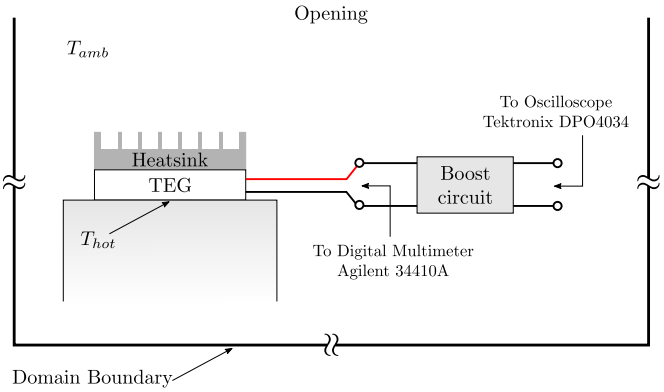

Fig. 1. Ilustration of the experimental setup. Dimensions not to scale.

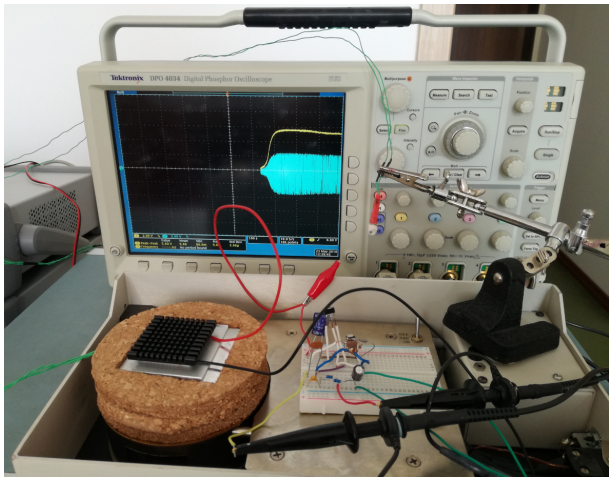

Fig. 2. Photograph of the experimental setup located inside the domain.

Prior to the experimental measurements for the step-up circuit, characterization of the assembly TEG–heatsink was performed in order to estimate values of the temperature difference needed for the generation of sufficient input voltage. The dependence of the open circuit voltage of the TEG (V_{TEGoc}) and the voltage provided by the TEG when loaded with $4\,\Omega$ resistance (V_{TEG}) as a function of temperature difference $\Delta T_{amb} = T_{hot} - T_{amb}$ for two different types of heatsinks is given in Fig. 3. In the temperature range of the interest, the open circuit voltage, as well as, the voltage under load increase

linearly with an increase of the temperature difference. The TEG with the aluminum heatsink generates higher voltages than the TEG with the metal foam heatsink. This is as expected considering thermal resistance values of the two heatsinks. For the TEG under load, the provided voltage is considerably lower than for open circuit condition due to the voltage drop at the internal resistance of the TEG and Peltier effect [20]. Also, the difference between voltages for the two heatsinks is less pronounced.

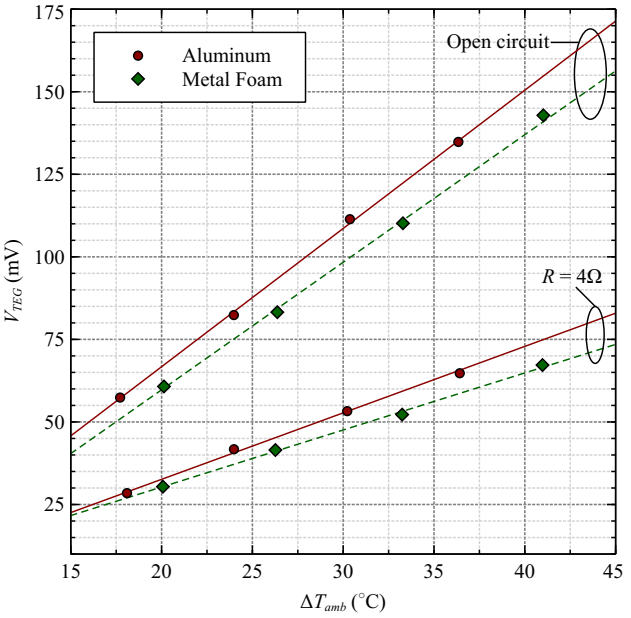

Fig. 3. Open circuit TEG voltage and loaded TEG voltage as a function of the temperature difference for an aluminum heatsink and a metal foam heatsink.

III. Design of Low-Voltage Step-Up Circuit

The most important requirements for step-up converter are as small as possible starting input voltage and as high as possible the power conversion efficiency. The voltage step-up ratio must be high enough to supply connected electronic circuitry with a required voltage value. Self-powered start-up from the applied low input voltages should ensure operation under worst case conditions, without any auxiliary power from a battery. The designed step-up converter is based on a FET-tuned oscillator with self-start up capability. The circuit relies on a Meissner-type oscillator that consists of the step-up transformer and a depletion mode n-type MOSFET [21]. A voltage doubler [22] is also included. The schematic of the circuit is shown in Fig. 4.

The depletion mode n-type MOSFET BSP149 (M_1) is chosen since it is in normally-on state at the considered low voltages due to its negative threshold voltage V_{th} [23]. The second advantage of this transistor is its small drain-source on-state resistance which ranges from $1.7\,\Omega$ to $3.5\,\Omega$. The charge pump capacitor C_1, which is an integral part of the voltage doubler circuit, has an effect on maximum output current capability. A minimum value of $1\,\text{nF}$ is recommended when operating from very low input voltages using the transformer with a ratio of $1:100$ [7]. Too large capacitor value can

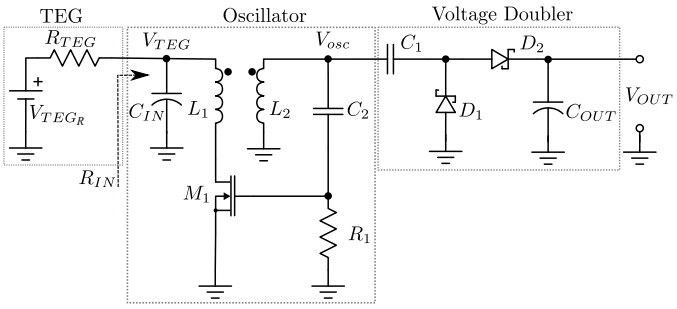

Fig. 4. Schematic of the low-voltage step-up circuit for thermal energy harvesting.

compromise circuit performance when operating at low input voltage or with high resistance sources. In this circuit, the ceramic capacitor of $C_1 = 100\,\text{nF}$ was chosen. Capacitor C_2 acts as a gate coupling capacitor. The value of this capacitor is chosen so that the oscillations start very quickly after the input voltage reaches $60\,\text{mV}$. The experimentally obtained value is $C_2 = 4.5\,\text{nF}$. Resistor R_1 provides a stable start of oscillations in the circuit. The set value of this resistor is $R_1 = 2.2\,\text{M}\Omega$. The Schottky diodes ($D_1$ and D_2) are used for the realization of the voltage doubler. These diodes are better in comparison with silicon diodes due to the lower forward voltage. For storing the harvested energy, the electrolytic capacitor C_{OUT} of $100\,\mu\text{F}$ is used.

The choice of transformer is particularly important in the design process of the circuit. The major features of the transformer for low voltage step-up oscillators are high quality factor Q, small footprint area and high turns ratio. The commercial miniature toroidal microtransformers with ferrite and magnetic low temperature co-fired ceramic cores are considered as one of the best choices for energy harvesting applications [6]. In this case, a commercial microtransformer with a ratio of $1:100$ was chosen. When the primary winding of a transformer is energized, a current flows through it. This current creates a magnetizing force H that produces the magnetic flux Φ of density B in the transformer core. When magnetizing force is increased from zero, the flux density increases up to a certain maximum value. Above this level, further increases of H results in no significant increase in B because magnetic material is saturated [24]. An ideal transformer has zero winding and core losses and unity coupling coefficient. In practice, all magnetic materials, once magnetized, retain some of their magnetization B_r even when the H is reduced to zero. The magnetizing force which must be applied to null the residual flux density is a coercive force H_c. Generally, microtransformers can experience large core losses due to eddy currents and hysteresis. The hysteresis losses result from the additional power needed to reverse the magnetic field in magnetic materials in the presence of alternating current.

The voltage source (V_{TEG}) that imposes the current through the primary winding L_1 and the normally on depletion mode MOSFET is connected to the step-up oscillator. This current induces a positive voltage at the secondary winding L_2 which increases the gate voltage of M_1 and thus primary winding current. When this current reaches the core saturation,

the secondary winding voltage starts to drop. The transistor starts turning off the current through the primary winding of the transformer which leads to reverse of the voltage at the secondary winding and the negative gate voltage. The transistor is driven near its off state, leading to a decrease of primary winding current, and thus, through the coupling of the transformer, less negative value of gate voltage. The transistor is turned on quickly and remains to conduct until the primary winding current approaches saturation so that the oscillation process starts again.

The signal from the step-up oscillator (V_{osc}) is fed to a half-wave voltage doubler. The voltage doubler circuit is composed of two sections: a clamp formed by C_1 and D_1, and a peak rectifier formed by D_2 and C_{OUT}. During the negative half cycle of an input voltage signal, diode D_1 conducts, charging capacitor C_1 up to the voltage $V_{C1} = V_{D1} - V_{OSC}$. Note that V_{OSC} marks amplitude of oscillator output voltage V_{osc}. During the positive half cycle of the input signal, diode D_1 is cut off and diode D_2 conducts charging capacitor C_{OUT}. If we adopt $V_{D1} = V_{D2} = V_D$, the output voltage will be:

$$V_{OUT} = V_{OSC} - V_{C1} - V_{D2} = 2(V_{OSC} - V_D) \; . \tag{3}$$

If diodes act as a short circuit in on state, the voltage across the capacitor C_{OUT} will discharge through the load during the negative half cycle at the input, and the capacitor is recharged up to $2V_{OSC}$ during the positive half cycle.

The small signal model of the step-up oscillator is shown in Fig. 5. The major parameters of the transistor and transformer that affect the oscillation condition are: g_m – transconductance of the MOS transistor, C_{gs} – gate-source capacitance of the MOS transistor, L_1 – primary inductance of the transformer, L_2 – secondary inductance of the transformer, R_{S1} – serial resistance of the primary winding, R_{S2} – serial resistance of the secondary winding, R_1 – external resistance, C_2 – external capacitance, M – mutual inductance of the transformer, k – coupling factor between the primary and secondary windings, where

$$M = k\sqrt{L_1 L_2} \; . \tag{4}$$

Note that $s = j\omega$. The current through the primary windings of the transformer, i.e. through the drain of the transistor is:

$$i_1 = g_m v_g \; . \tag{5}$$

Based on Kirchhoff's law, for the circuit in Fig. 5 can be written:

$$\frac{sMg_m v_g - v_g}{R_{s2} + sL_2 + \frac{1}{sC_2}} - \frac{v_g}{R_1} - v_g s C_{gs} = 0 \; . \tag{6}$$

By solving Eq. (6) we obtain:

$$-\omega C_2 + j\omega^2 C_2 M g_m = \frac{\omega R_{s2} C_2}{R_1} - \omega C_{gs}(\omega^2 L_2 C_2 - 1) + j(\omega^2 C_{gs} R_{s2} C_2) + j\frac{\omega^2 L_2 C_2 - 1}{R_1} \; . \tag{7}$$

The resonant frequency will be obtained from the condition that the real part of Eq. (7) is equal to zero:

$$\omega^2 C_{gs} C_2 L_2 - \frac{R_{s2} C_2}{R_1} - C_{gs} - C_2 = 0 \; . \tag{8}$$

By solving Eq. (8), and taking into account that $\omega = 2\pi f$, we get oscillation frequency f as:

$$f = \frac{1}{2\pi}\sqrt{\frac{R_{s2}C_2 + R_1 C_{gs} + R_1 C_2}{R_1 C_{gs} L_2 C_2}} \; . \tag{9}$$

The LCR meter Agilent 4284A was used to obtain necessary

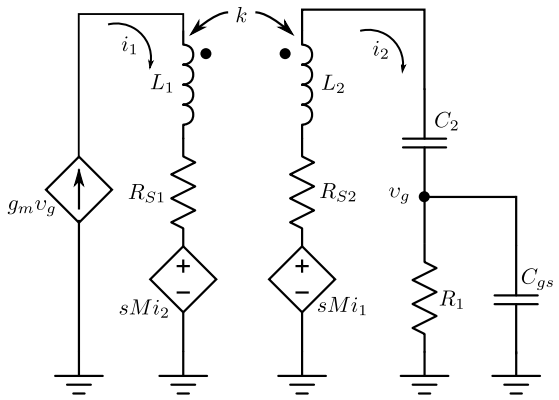

Fig. 5. Small signal equivalent model of the step-up oscillator.

data for analytical analysis of the oscillator circuit. Measured inductance and resistance values are shown in Table I. Based on MOSFET BSP149 datasheet [23] the value of the input capacitance C_{gs} is 850 pF. By replacing parameter values in Eq. (9), the frequency of the oscillator 129.9 kHz is calculated.

TABLE I
MEASURED PARAMETER VALUES OF THE TRANSFORMER AT 1 kHz

Transformer parameter	Measured value
Primary inductance - L_1	0.2 µH
Serial resistance of the primary winding - R_{S1}	7 mΩ
Secondary inductance - L_2	2.1 mH
Serial resistance of the secondary winding - R_{S2}	5.2 Ω

IV. RESULTS AND DISCUSSION

The voltage generated by the TEG with aluminum heatsink, the oscillator voltage and the voltage at the output capacitor as a function of time are presented in Fig. 6. The shown experimental results were obtained for the TEG hot side temperature $T_{hot} = 56.8\,^{\circ}\mathrm{C}$ and the ambient temperature $T_{amb} = 24.5\,^{\circ}\mathrm{C}$. In this case, for temperature difference of $\Delta T_{amb} = 32.3\,^{\circ}\mathrm{C}$, voltage of $V_{TEG} = 59\,\mathrm{mV}$ is generated. Immediately upon establishing of the voltage, the oscillations and the increase of the output voltage start. After 230 s the output voltage of 3.3 V is reached. The analysis shows that after 300 s TEG is in steady state and the output capacitor is charged to a value of 6.2 V. The experimentally obtained output voltage value is in accordance with Eq. (3), since the oscillator voltage amplitude in the positive half cycle is about 3 V.

The characteristic voltage values obtained for the TEG with metal foam heatsink resemble the ones shown in Fig. 6. However, it requires a slightly higher temperature difference ($\Delta T_{amb} = 35.9\,^{\circ}\mathrm{C}$) than the TEG with the aluminum heatsink to achieve the same voltage that drives the oscillator

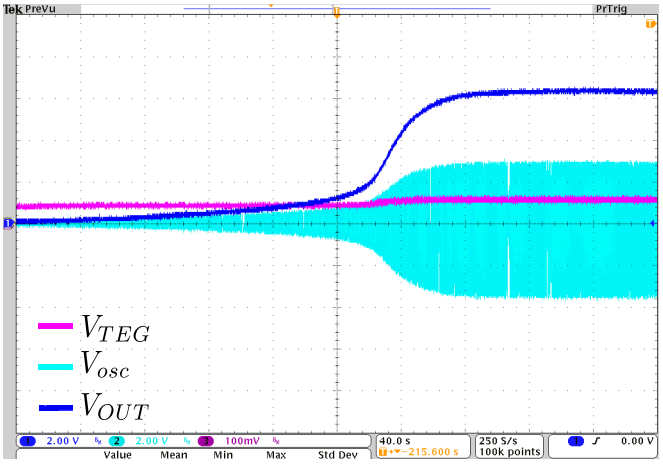

Fig. 6. Voltage generated by the TEG with aluminum heatsink, the oscillator voltage and the voltage at the output capacitor as a function of time. X-axis: 40 s/div, Y-axis: 2 V/div (for V_{osc} and V_{OUT}); 100 mV/div (for V_{TEG}).

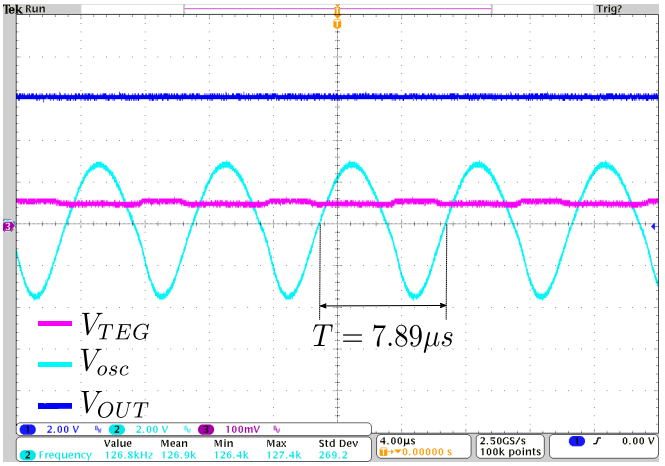

Fig. 7. Zoom In - Voltage generated by the TEG with aluminum heatsink, the oscillator voltage and the voltage at the output capacitor as a function of time. X-axis: 4 µs/div, Y-axis: 2 V/div (for V_{osc} and V_{OUT}); 100 mV/div (for V_{TEG}).

circuit. In this case, the necessary hot side temperature is $T_{hot} = 60.4\,°\mathrm{C}$ for the same ambient temperature. These results are in compliance with characterization data for the two TEG–heatsink assemblies presented in Fig. 3. It can be concluded that metal foam heatsinks can be also incorporated into the design of thermal harvesting systems under appropriate thermal conditions. Even though their cooling performances are somewhat lower than that of aluminum heatsinks, their advantages are compact form, ultra low profile, and low weight.

Based on the data from Fig. 3, the value of the input resistance of the step-up circuit R_{IN} while charging output capacitance is estimated to be approximately $4\,\Omega$. Analysis of oscillator voltage using the oscilloscope (Fig. 7) found that the frequency of oscillation is 126.9 kHz. It can be concluded that the results obtained from the analytical model and experiments are in excellent agreement.

Considering the power conversion efficiency, presented circuitry enables around 20% of the input electrical power obtained by the TEG to be transferred to the output capacitor. Having in mind that the commercial integrated step-up converter and power manager like LTC3108 [7] has efficiency in the range 5–40% depending on the input voltage value, our obtained value is quite satisfactory.

During the analysis of the circuit, it was noticed that the oscillation stops for a period of time much longer than the period of oscillations (Fig. 8). This phenomenon is called squegging [7]. It occurs when a charge builds up on the capacitor C_2, such that DC bias point shifts and oscillations are extinguished for a certain period of time. When the charge on the capacitor leaks out, oscillations resume. It is difficult to predict when this phenomenon will occur. While squegging is not harmful, it reduces the average output current capability. Squegging can easily be avoided by the addition of a leakage resistor in parallel with C_2 capacitor. Resistor values in the range of $100\,\mathrm{k}\Omega$ to $1\,\mathrm{M}\Omega$ are sufficient to eliminate squegging without having any negative impact on the performance.

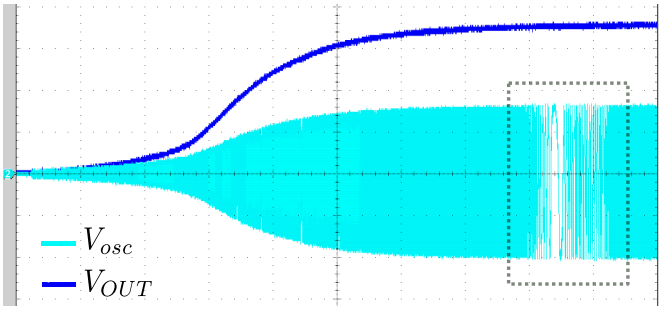

Fig. 8. Illustration of the squegging phenomenon.

V. Conclusion

This paper describes low-voltage step-up circuit design for thermal energy harvesting application under natural convection. Analytically determined frequency of the Meissner oscillator, based on the derived model for small signals, showed a good agreement with experimentally obtained results. By analyzing the voltage vaweforms at characteristic points in the circuit, it was found that at hot side–ambient temperature difference of about 30 °C, TEG with heatsink generates a voltage sufficient to start the oscillator (about 60 mV). After about 4 min, the output voltage at the constant temperature difference can be boosted to 3.3 V. The maximum obtained DC voltage is about 6 V. This circuit can be used to boost low voltage from different energy harvesting sources.

ABSTRACT

In this work an overview of Micro Electromechanical Systems (MEMS)-based microfluidic platforms for different applications is presented. Microfluidics refers to a set of technologies that control the flow of liquids or gases through miniaturized systems in typical amounts of nano- and pico- liters. Microfluidic devices are characterized by microchannels with characteristic dimensions in the micrometer range. The main techniques, technologies and materials used for fabrication of MEMS microfluidic devices and systems are presented. The used materials and their properties are very important for the final characteristics and functionalities of devices. As an example, the design and fabrication of our opto-fluidic lab-on-a-chip device based on silicon and pyrex glass is given.

Analysis of the Fundamental Detection Limit in Microfluidic Chemical and Biological Sensors

Ivana Jokić, Katarina Radulović, Miloš Frantlović, Zoran Djurić, Katarina Cvetanović Zobenica, Predrag M. Krstajić

***Abstract*—Detection limits in microfluidic chemical and biological sensors, which determine the range of analyte concentrations reliably detectable by the sensor, are important sensor parameters. The lower limit of detection, defined as the lowest concentration that can be distinguished from noise, has its minimum determined by the fundamental adsorption-desorption (AD) noise, inevitable in adsorption-based devices. In this work, we analyze this fundamental detection limit, particularly considering the influence of mass transfer processes in microfluidic devices. For that purpose, we derive the expression for the sensor's signal-to-noise ratio (SNR), which takes into account the AD noise, and then the equation for the minimal analyte concentration at which the SNR has a sufficiently high value for reliable analyte detection. Subsequently, we analyze the mass transfer influence on the sensor's maximal achievable signal-to-noise ratio and on the fundamental detection limit. The results of the analysis show a significant mass transfer influence on these important sensor performance metrics. They also provide guidelines for achieving the sensor's best possible detection performance through the optimization of the sensor design and operating conditions.**

***Index Terms*—Microfluidic sensor; biosensor; chemical sensor; detection limit; mass transfer; signal-to-noise ratio.**

I. Introduction

Detection of chemical substances or biological species (viruses, bacteria, DNA, proteins, cells), and measurement of their concentration in samples are performed in order to monitor the pollution present in the environment, food and water, or the health condition of living organisms. Therefore, their significance in environment protection, agriculture, food industry and healthcare is high. In these fields it is especially important to obtain reliable measurement results in a short period of time, and often at locations which are far from laboratories where conventional sample analysis can be performed. The concentrations to be detected are typically very low, requiring very sensitive measurement equipment and methods. Current research activities are aimed toward the development of highly sensitive and portable chemical and biological sensors based on micro- and nanotechnologies, which are recognized as promising for the mentioned applications. Among them are microfluidic adsorption-based sensors [1, 2].

In microfluidic devices a sensing element is placed in a reaction chamber, which is a part of a microfluidic system for sample delivery and analyte detection. The principle of operation of adsorption-based chemical and biological sensors is based on the adsorption-desorption (AD) process of analyte particles (gas atoms or molecules, biomolecules or micro-organisms) on the sensor's sensing surface, which causes a measurable change of some of the sensor's parameters, and yields the sensor's output signal. Therefore, the output signal is determined by the number of adsorbed analyte particles, which depends on the analyte concentration in the analyzed sample.

The instantaneous number of adsorbed particles depends on AD and mass transfer (convection and diffusion) processes of analyte particles, by which they are transported through the sensor's reaction chamber to and from the adsorption sites on the sensing surface where they bind and unbind. The random nature of these coupled processes results in inevitable stochastic fluctuations of the number of adsorbed particles, and therefore in stochastic fluctuations of the sensor's response, known as AD noise. This fundamental noise sets the ultimate noise performance of adsorption-based sensors, determining the maximal achievable signal-to-noise ratio (SNR), and the minimal detectable analyte concentration. The AD noise analysis is, therefore, significant for optimization of adsorption-based sensors in terms of improved sensing performance. It is based on the stochastic analysis of fluctuations of the number of adsorbed analyte particles.

Stochastic mathematical models for the analysis of fluctuations of the number of adsorbed particles that take into account mass transfer processes, are rare [3-5]. While those presented in [3, 4] consider coupled AD process and diffusion of analyte particles, the stochastic model presented in [5] takes into account the coupling of AD process, diffusion and

convection, which corresponds to realistic operating conditions in microfluidic sensors. In the mentioned literature the stochastic models were used for the analysis of the expected value and variance of the number of adsorbed particles, which reveal the stochastic response kinetics and sensor AD noise, as well as for the analysis of the maximal possible sensor's SNR. The influence of mass transfer on sensor's SNR and detection limit has not been quantitatively analyzed in particular until now.

In this work, starting from the stochastic response model of adsorption-based sensors, which considers the influence of coupled stochastic AD and mass transfer processes on the change of the number of adsorbed particles [5], we derive the expression for the sensor's SNR that takes into account the AD noise. Subsequently we obtain the equation for determination of the minimal analyte concentration at which the SNR has a sufficiently high value for reliable analyte detection. After that, we analyze the SNR and the minimal concentration level of the analyte in microfluidic chemical and biological sensors, considering the influence of mass transfer of particles on these important sensor performance metrics. In numerical simulations that we perform, we consider the range of mass transfer coefficients typical for macromolecules that are detected by state-of-the-art biosensors. The presented results enable the analysis of the dependence of the minimal detectable signal on the sensor design parameters, and are useful for achieving the improved sensing performance.

II. THEORETICAL ANALYSIS

The fluctuations of the output signal of adsorption-based chemical and biological sensors result from various kinds of noise, i.e. the noise originating from the stochastic nature of physical processes (AD and mass transfer) which are essential for analyte detection by the sensing element, and the noises from the sensor transduction mechanism and the read-out circuitry. The former, known as AD noise, poses the fundamental detection and quantification limits of analyte concentration, inherent to all adsorption-based devices. In some cases, AD noise can dominate compared to other noise sources [3]. Assuming that the transducer noise and the noise of read-out circuitry are minimized by applying appropriate techniques, reduction of the inevitable AD noise remains a means of achieving the sensor's best possible detection performance, i.e. maximization of sensor's signal-to-noise ratio and approaching its lowest possible detection limit. Therefore, the analysis of the sensor SNR excluding the transducer and read-out circuitry noise yields the guidelines for lowering the fundamental detection limit.

By assuming a linear relation between the sensor response and the number of adsorbed particles, the expected value of stochastic response is $\langle r\rangle = m\langle N\rangle$ (where $\langle N\rangle$ is the expected value of the number of adsorbed analyte particles, and m is the proportionality factor equal to the average contribution of a single particle adsorption to the sensor response), sensor's AD noise is $\sigma_{r,AD}^2 = m^2\sigma_N^2$ (where σ_N^2 is the variance of the number of adsorbed particles), so the sensor's maximal SNR (the ratio of signal power and noise power), which is determined only by the fundamental AD noise, is

$$SNR = \frac{< N >^2}{\sigma_N^2} \tag{1}$$

Here we consider the SNR in the steady state (established after all transient processes have ended), in which the measurements are preferably carried out in practice. We use the stochastic model presented in [5], describing the number of adsorbed particles that randomly fluctuates due to coupled AD and mass transfer processes. Based on the model, the steady-state expected value and variance of the number of adsorbed particles are given by expressions

$$\langle N\rangle = \frac{N_m k_a C}{k_a C + k_d + \frac{k_a k_d}{k_m A}} \tag{2}$$

$$\sigma_N^2 = k_d\langle N\rangle \frac{\left[1 + (N_m - \langle N\rangle)\frac{k_a}{k_m A}\right]^2}{k_a C + k_d + \frac{k_a k_d N_m}{k_m A}} \tag{3}$$

respectively, where C is the concentration of target particles in the analyzed sample, N_m is the number of adsorption sites on the sensing surface, k_a and k_d are the adsorption and desorption rate constants, k_m is the mass transfer coefficient which models the combined effect of diffusion and convection on particle transport to the surface adsorption sites and from them, and A is the sensing surface area. k_m depends on geometrical parameters of the sensing system, the flow rate of the sample, and the diffusivity of the analyte [6]. Based on Eqs. (1)-(3) we obtain

$$SNR = \frac{k_a C N_m}{k_d} \cdot \frac{\left[k_a C + k_d\left(1 + \frac{k_a}{k_m A}\right)\right]\left[k_a C + k_d\left(1 + \frac{k_a N_m}{k_m A}\right)\right]}{\left[k_a C + k_d\left(1 + \frac{k_a}{k_m A}\right)\left(1 + \frac{k_a N_m}{k_m A}\right)\right]^2} \tag{4}$$

This expression clearly shows the dependence of the sensor's maximal achievable SNR on the mass transfer coefficient, and thus enables the analysis of the influence of mass transfer process on the SNR.

The dynamic range, defined as the range of analyte concentrations reliably detectable by the sensor, is also one of important sensor characteristics. The upper limit of the dynamic range is determined by the sensor saturation, i.e. the limited number of adsorption sites on the sensing surface. It will not be considered in this paper. The lower limit of the

dynamic range is the lowest concentration that can be distinguished from noise. This detection limit is determined as the analyte concentration level at which the sensor's SNR is equal to a minimal acceptable value for reliable detection. Let us assume that it is a value F. The condition $SNR=F$, where the SNR is given by Eq. (4), yields the equation for the fundamental detection limit C_{min}

$$\begin{aligned}&(k_aC_{\min})^3\frac{N_m}{k_d}+(k_aC_{\min})^2\left[N_m\left(2+\frac{k_a}{k_mA}+\frac{k_aN_m}{k_mA}\right)-F\right]\\&+(k_aC_{\min})\left[(N_m-2F)k_d\left(1+\frac{k_a}{k_mA}\right)\left(1+\frac{k_aN_m}{k_mA}\right)\right]\\&-Fk_d^2\left(1+\frac{k_a}{k_mA}\right)^2\left(1+\frac{k_aN_m}{k_mA}\right)^2=0\end{aligned} \tag{5}$$

By numerically solving the Eq. (5) for C_{min} for a series of the coefficient k_m values, the analysis can be performed of the mass transfer effect on the minimal concentration that can be reliably detected at the required SNR value F.

III. Results and Discussion

By using the derived expressions (Eqs. (4) and (5)) we analyze the SNR and the minimal concentration level at which the SNR has the required value that ensures reliable analyte detection in microfluidic chemical and biological sensors. We particularly consider the influence of mass transfer of particles on these important performance characteristics, after the steady state of all relevant transient processes has been reached.

A biosensor for detection of macromolecules (proteins), with the sensing surface area $A=10^{-11}$ m^2, and the adsorption sites surface density $n_m=N_m/A=3\cdot10^{17}$ 1/m^2 is used in the analysis. The parameters of the AD process are $k_a=1.33\cdot10^{-19}$ m^3/s and $k_d=0.08$ 1/s. The range of the mass transfer coefficient k_m is from 10^{-6} m/s to 10^{-1} m/s.

Fig. 1 shows the biosensor's SNR as a function of the mass transfer coefficient at the analyte concentration $C=6\cdot10^{16}$ 1/m^3 (the solid curve). The dashed curve represents the SNR obtained by using the stochastic model that neglects the mass transfer influence [5], according to which

$$SNR_i=\frac{k_aCN_m}{k_d} \tag{6}$$

The diagram in Fig. 1 shows that the SNR value is lower for lower mass transfer rates (i.e, for lower k_m). Hence, slow mass transfer reduces the maximal possible sensor's SNR. In the considered range of k_m values SNR exhibits a change of almost three orders of magnitude. As k_m value increases, SNR monotonically increases and reaches its maximal value equal to that obtained by using the model that does not take into account mass transfer (Eq. (6)). Therefore, when mass transfer is sufficiently fast, its influence becomes negligible. In the analyzed case, mass transfer with the coefficient greater than 10^{-2} m/s does not lead to the decrease of the sensor's SNR.

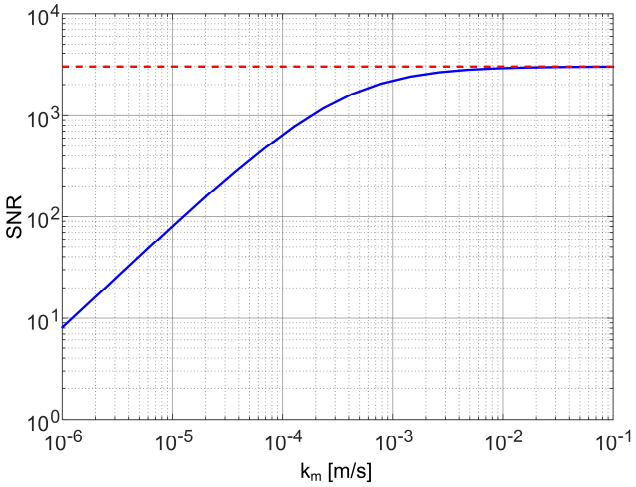

Fig. 1 The sensor's maximal achievable SNR depending on the mass transfer coefficient (solid line), and SNR obtained by neglecting the mass transfer influence (dashed line).

The minimal concentration level for $SNR=9$ (a value considered as required for reliable analyte detection [7]) is shown as a function of k_m in Fig. 2 (solid line). C_{min} obtained from Eq. (6) for $SNR_i=F$

$$C_{\min,i}=\frac{Fk_d}{k_aN_m} \tag{7}$$

i.e. by the analysis that neglects the mass transfer influence, is represented by a dashed line in the same diagram, also for $F=9$.

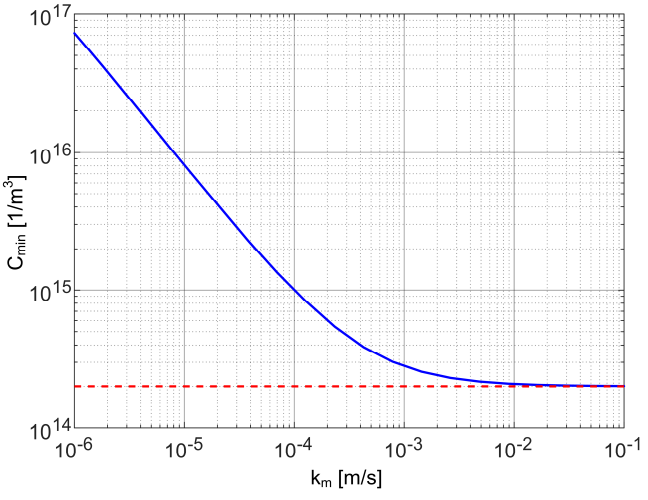

Fig. 2 The dependence of the sensor's fundamental detection limit on the mass transfer coefficient (solid line), and the same parameter obtained by neglecting the mass transfer influence (dashed line).

Fig. 2 shows that mass transfer significantly influences C_{min} in such a way that slow mass transfer increases the

concentration value and thus degrades the sensor performance. When the mass transfer is sufficiently fast, its effect becomes negligible, and C_{min} reaches the lowest value equal to $C_{min,i}$.

The presented analysis shows that it is necessary to consider the mass transfer influence when the optimization of microfluidic sensors and their operating conditions is performed aiming to achieve the required SNR value for reliable analyte detection, i.e. to ensure analyte detection in a certain concentration range.

IV. Conclusions

In this paper the theory is presented that enables the analysis of mass transfer influence on the maximal achievable SNR, and of the lowest detectable analyte concentration in microfluidic sensors. The analysis has shown that a slow mass transfer degrades these important sensor performance parameters.

The mass transfer coefficient is a known function of the sensing system geometrical parameters, the flow rate of the sample through the microfluidic reaction chamber, and the diffusivity of the analyte. Therefore, the presented theory enables the analysis of the dependences of the considered sensor performance metrics on sensor design parameters and operating conditions, and thus provides the means for sensor optimization.

A consideration of the use of ICTM SP-12 pressure sensor for ultrasound sensing

Jelena Stevanović, Žarko Lazić, Milče M. Smiljanić, Katarina Radulović, Danijela Randjelović, *Member, IEEE*, Miloš Frantlović and Milija Sarajlić, *Member, IEEE*

***Abstract*— A consideration study for the application of the pressure sensor SP-12 developed and produced by ICTM CMT as an ultrasound sensor is given. The interaction of ultrasound with the sensor's membrane was analytically described, but for the initial examination of its performance, Finite Elements Method simulation was applied. The sensor SP-12 has eigenfrequencies in the range from 200 kHz to the frequencies higher than 2 MHz. The amplitude of the output signal, which is proportional to Von Mises stress, is highest for the lowest frequency, and it exponentially decreases as the eigenfrequencies increase. This makes the sensor suitable for the ultrasound measurements in the range of hundreds of kHz.**

***Index Terms*—pressure sensor; ultrasound; Von Mises stress; piezoresistor; eigenfrequencies.**

I. Introduction

Ultrasound measurement and detection have many important applications of everyday life and industry. Navigation of vehicles [1], medical examination [2], materials testing [3] and sonication (ultrasound processing of liquids) [4] are some of the applications. Sensors and detectors for ultrasound comprise different models of operation, for instance capacitive transducers [5], Fiber Bragg Grating [6] or Spherical-Omnidirectional Ultrasound Transducers [7].

One possibility for the ultrasound detection is measurement of the pressure differences it makes on the membrane of the pressure sensor. For this purpose, device originally developed as a pressure sensor can serve as an ultrasound sensor. At ICTM CMT in Belgrade, Serbia, there has been a long history of pressure sensors research and development, from the model SP-6 developed in 1980s to the model SP-12, which is currently in production [8]. This work examines possibility of application of the SP-12 pressure sensor for ultrasound sensing and gives brief overview on analytical model of membrane under mechanical stress together with numerical simulations. A proposal of experimental procedure is also given. In the presented analysis it is investigated whether the SP-12 can serve as an ultrasound sensor at the frequencies equal to its eigenfrequencies.

II. Analytical model of SP-12 membrane under mechanical stress

A. Description of sensor SP-12

The SP-12 sensor is fabricated on double-side polished single crystal n-type 3`` silicon wafer, with the resistivity of 3-5 Ωcm [8]. Four piezoresistors are formed by the photolithography process and thermal diffusion of boron at 920°C. The effective length and width of each piezoresistor are 135 µm and 5 µm, respectively. The concentration of dopants is between $1.5 \cdot 10^{20}$ cm^{-3} and $2 \cdot 10^{20}$ cm^{-3} [8].

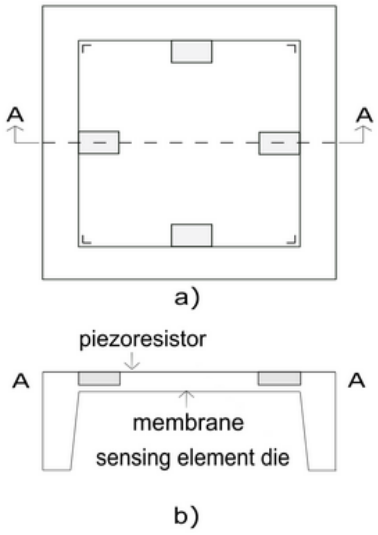

Fig 1. Schematic illustration of the SP-12 sensing element die: a) top view of the sensor; b) cross section through the middle of the diaphragm

Positions of piezoresistors on the silicon membrane are important for the sensitivity of the device. All of them are located near the edge of the membrane, two in parallel and two in the transversal direction, as it is shown in Fig. 1. They are connected in the Wheatstone bridge. The resistor positions are optimal in terms of the highest possible sensitivity and linearity of the output signal. The membrane is square of dimensions 1000 µm × 1000 µm, fabricated by wet anisotropic etching of silicon of the bottom side on the wafer [8]. The obtained thickness of the membrane is 18

μm. Metallization is done by aluminum sputtering under the base pressure of $2 \cdot 10^{-6}$ mbar. The overall size of the sensing element die is 2000 μm × 2000 μm × 380 μm [8]. After the fabrication of the die, it is anodically bonded to a 1.7 mm thick glass support [8].

B. Analytical model

The behavior of the sensor's membrane under mechanical stress was analytically modeled by using an approximation of the classical plate theory. According to this theory, differential equation for anisotropic clamped rectangular thin plate is [9]:

$$D_x \frac{\partial^4 \omega}{\partial x^4} + 2H \frac{\partial^4 \omega}{\partial x^2 \partial y^2} + D_y \frac{\partial^4 \omega}{\partial y^4} = q \qquad (1)$$

where ω is the deflection of the plate midsurface (displacement in the z direction), q is the intensity of uniform load on the plane, H is the parameter highly dependent on symmetry, and for materials with orthotropic elasticity values like single-crystal (100) silicon [10], it has a value of $\sqrt{(D_x D_y)}$ and D_x and D_y are the flexural rigidities in two orthogonal directions, and for orthotropic materials it is given by [11]:

$$D_{x/y} = \frac{E_{x/y} h^3}{12(1 - \nu_{xy} \cdot \nu_{yx})}. \qquad (2)$$

Here E is the modulus of elasticity in tension and compression, ν is the Poisson's ratio and h is the plate thickness. The boundary conditions for a clamped thin plate are [9]:

$$\omega = 0, \frac{\partial^2 \omega}{\partial x^2} = 0, \frac{\partial^2 \omega}{\partial y^2} = 0, \qquad (3)$$

for $x = 0$ and $x = a$, and $y = 0$ and $y = b$, where a and b indicate the plate edge lengths. In other words, the bending moment at the edge of the membrane is zero. For the square plate, a and b are equal. If the load q is represented in the form of a double trigonometric series, a solution of the differential equation (1) can be presented in the form of [9]:

$$\omega = \sum_{m=1,3,5\ldots}^{\infty} \sum_{n=1,3,5\ldots}^{\infty} a_{mn} \sin \frac{m\pi x}{a} \sin \frac{n\pi y}{b}. \qquad (4)$$

By substituting this solution in Eq. (1), the expression for coefficients a_{mn} is found. In the case of uniform load the deflection surface is symmetrical with respect to the axes $x = a/2$ and $y = b/2$. For that reason all terms with even numbers for m or n in series (4) do not exist. Hence, the final solution of Eq. (1) is [9]:

$$\omega = \frac{16q}{\pi^6} \sum_{m=1,3,5\ldots}^{\infty} \sum_{n=1,3,5\ldots}^{\infty} \frac{\sin \frac{m\pi x}{a} \sin \frac{n\pi y}{b}}{mn\left(\frac{m^4}{a^4} D_x + \frac{2m^2 n^2}{a^2 b^2} H + \frac{n^4}{b^4} D_y\right)}. \qquad (5)$$

For orthotropic (100) silicon membrane, values of the modulus of elasticity are $E_x = E_y = 169$ *GPa* [12], while the values of the Poisson's ratio, when the extension is applied along x, i.e. y direction, are $\nu_{xy} = \nu_{yx} = 0.064$ [12]. By including these values in Eq. (2), flexural rigidities D_x and D_y are calculated to be $8{,}25 \cdot 10^{-5}$ *Pa·m*^{3}. We assume that amplitude of the ultrasound pressure is 100 Pa. Deflection at the center of the orthotropic plate with $a = b$ and $D_x = D_y$ can be expressed by the formula [9]:

$$\omega = 0.00407 \cdot \frac{q \cdot b^4}{D_y}, \qquad (6)$$

and is estimated to *4,9 nm*. It is important to mention that this calculated deflection refers to the membrane's center when static pressure is applied. That means resonant frequency (eigenfrequency) contribution is not included in the calculation. In order to obtain values of deflection for membrane's resonant frequency when harmonic perturbation like ultrasound is applied, further analysis is needed, whose complexity overcomes the scope of this paper.

III. Finite Elements Method Model of Eigenfrequencies

The eigenfrequencies of the SP-12 membrane can be found from the FEM model by solving the eigenvalue problem that arises from the equations if velocity is considered to be unknown. A standard matrix form of the dynamic equation of motion can be written as [13]:

$$[M]\frac{d^2 y}{dt^2} + [B]\frac{dy}{dt} + [K]y = 0, \qquad (7)$$

where y is the vector of nodal displacement under the external force vector, and [M], [B] and [K] are the element matrices for mass, damping and stiffness for the whole structure. Under free vibration, the eigenfrequencies and the mode shapes of a multiple degree of freedom system are the solutions of the eigenvalues problem.

FEM codes are designed to solve systems of equations like Eq. (6), with one equation for each of the relevant planes. It is possible to determine the eigenvalues and eigenvectors after integrating the approximate solution and forming the matrices.

The finite element modeling was performed using COMSOL Multiphysics software [14] which provides data about the interaction between the ultrasound and silicon membrane. A quarter of the whole tested diaphragm is chosen for the model and appropriate boundary conditions and symmetry are defined in order to simplify the construction of the model and subsequent calculation. The intensity of ultrasound pressure in boundary load is set to value of 100 Pa. In order to obtain structural response of harmonic load on membrane, Frequency Domain Study was applied. Range of ultrasound frequencies is selected to include the values of the eigenfrequencies, obtained as results of Eigenfrequency Analysis performed before the mentioned study. The maximum of displacements and Von Mises stresses appear on frequencies values that correspond to the eigenfrequencies of the tested membrane.

Results of the simulation are shown in Figs. 2-6 for the first five eigenfrequencies. Values of Von Mises stresses are listed in the Table 1 only for the positions of interest, which coincide with position of SP-12 piezoresistors. These positions are marked in Figs. 2-6 with the white arrows.

TABLE I
NUMERICAL RESULTS OF THE SIMULATION

eigenfrequency (Hz)	Von Mises stress (Pa)	membrane central point amplitude (μm)
$2.59 \cdot 10^5$	$1.13 \cdot 10^9$	10.89
$9.35 \cdot 10^5$	$8.45 \cdot 10^8$	1.03
$9.39 \cdot 10^5$	$4.45 \cdot 10^7$	0.59
$1.55 \cdot 10^6$	$4.06 \cdot 10^6$	$36 \cdot 10^{-3}$
$1.80 \cdot 10^6$	$1.72 \cdot 10^5$	$44 \cdot 10^{-6}$

IV. Proposal of the Experiment

In the proposed experimental set-up (Fig. 7), the ultrasound source will be a specifically shaped material from the group of piezoelectric ceramics. The SP-12 sensor will be connected to a constant current source which provides the excitation current of 5 mA. The output of the SP-12 sensor is connected to a spectrum analyzer. A maximum amplitude position in a digital record of the analyzer is expected to coincide with simulation results from Comsol. A potential problem of the experimental set-up would be the choice of the appropriate ultrasound source, whose range of soundwave frequencies should also include the resonant frequencies of the tested silicon membrane.

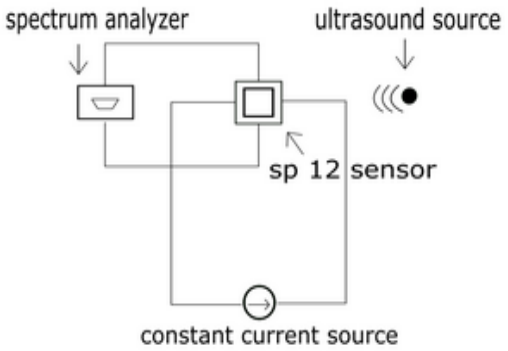

Fig 7. Schematic illustration of the proposed experiment

V. Conclusion

The purpose of this consideration study, was to examine the suitability of the ICTM CMT pressure sensor SP-12 for ultrasound detection. The interaction of mechanical pressure with the sensors's membrane was analytically described and numerically simulated. It was shown that this type of sensor has a potential to be used as ultrasound sensor. The range of ultrasound frequencies that can be probed corresponds to the silicon membrane eigenfrequencies.

It was noticed that stress at the positions of the piezoresistors has the highest value for the first two mode shapes. Therefore, eigenfrequencies that correspond to those mode shapes will be of our interest for the future ultrasound detection and measurement. Experimental testing is in preparation, where SP-12 will be connected in electrical circuitry in the similar way as pressure sensor, but the read-out will be performed by spectrum analyzer. The degree of agreement between analytical and numerical predictions with the experimental results will be investigated.

Consideration of Thin Film Ionization Vacuum Pressure Sensor

Marko Bošković, Danijela Randjelović, *Member, IEEE*, Milena Rašljić, Katarina Cvetanović-Zobenica, Žarko Lazić, Milče M. Smiljanić, and Milija Sarajlić, *Member, IEEE*

***Abstract*— A novel concept of vacuum pressure sensor based on thin film technology is presented. The sensor is designed as a 1 μm thick aluminium film patterned as a structure of wedges facing each other along a sharp tip. The distance between the wedge tips is 3 μm. This structure is obtained by laser writing in vector mode. Parts of the sensor structure are fabricated and measured. Analytical consideration of the proposed structure is given together with the concept of the experimental set up for testing of the sensor.**

***Index Terms*—Pressure sensor; DC discharge; Electrical conductivity of gases.**

I. Introduction

Vacuum technology is very important in many scientific disciplines and industrial processes [1]. Measurement of the vacuum pressure depends on the range of vacuum, namely rough vacuum, medium vacuum, high or ultra-high vacuum (UHV). For measurements of rough vacuum, from atmospheric pressure down to 0.1 Pa, gauges like Pirani or mechanical manometers are used [2, 3, 4]. For high vacuum, or pressure lower than 0.1 Pa ionization gauges are used [5].

In this work, an ionization sensor of vacuum is designed, modelled by analytical formulas, and part of it is fabricated. Fabrication in the proposed technology of direct laser writing is feasible but it takes relatively long time for the machine to finish one production cycle.

Aim of this work is to examine whether it is possible to determine gas pressure by measuring the conductivity of gases with a microdevice. In the following, proposed sensor design and discussion of the proposed design pattern are given. Characteristics of fabricated sensor part are examined by Atomic Force Microscopy measurements. Afterwards, some theoretical background of electrical conductivity in gases is considered and calculations for proposed structure are performed. Last part of paper gives proposal for measurement set-up and schematic for calibration of the sensor.

II. Sensor Design and Fabrication

The sensor is designed in four bunches, each with two pads. Each bunch consists of four stripes on one pad and five on another, with wedges which make a fringe pattern between them, Fig. 1. Each stripe is patterned on both sides with a series of wedges which are facing the wedges of the opposite stripe along the sharp tip. Enlarged detail of fringes (red rectangle in Fig. 1) is given in Fig. 2. The shortest distance between the tips is 3 μm.

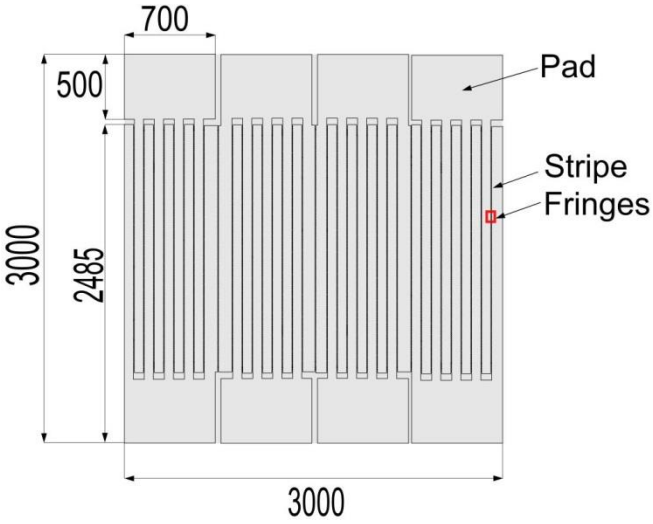

Fig. 1. Proposed design of the vacuum pressure sensor. Red rectangle is shown in Fig. 2. All units are in micrometers.

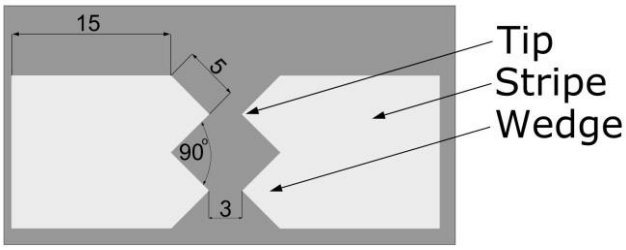

Fig. 2. Enlarged detail of the proposed design (red rectangle in Fig.1). Units are in micrometers.

The technology needed for the fabrication of this type of the designed structures was already developed at ICTM-CMT [6]. With this technology, it was possible to fabricate the lines with the period of 6 μm and clearance between 2 μm and 3 μm using Laser Writer (LW405, MicroTech, Italy) in vector mode. Vector mode enables a machine to draw continuous lines and the width of the line is defined by

the time of photoresist exposure and subsequent development.

A part of the proposed pattern for the vacuum pressure sensor is shown in Fig. 3.

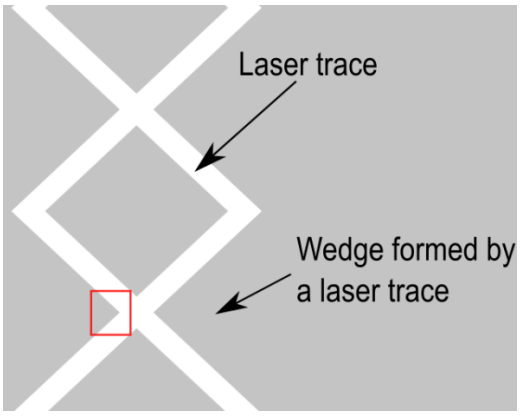

Fig. 3. A detail of proposed pattern and marked area where AFM scan was performed (red square).

The white line in Fig. 3 represents areas of wafer which will be exposed to laser radiation. After photolithography, we get structure similar to the structure shown in Fig. 2. If lines are 2 µm wide and are crossing each other on 90 degrees angle, calculated distance between wedge tips (electrodes) is 2.83 µm. Pattern was drawn using CleWin software [7].

The sensor was fabricated in a planar technology used for microelectronic devices. On a 3 inch wafer, 380 µm thick, <100> orientation, 3-5 Ωcm resistivity, n-type, one side polished, SiO_2 layer was grown by thermal oxidation at 1100 ℃ for 105 minutes. After thermal oxidation aluminium with 1% of silicon (Al 1% Si) was sputtered by DC Magnetron Sputtering. The wafer was then coated with photoresist AZ 1505 (MicroChemicals, Germany), 0.5 µm thick by spin coating. The wafer prepared in this way was then exposed to laser radiation using direct laser writer (LW405, MicroTech, Italy, 405 nm wavelength) in vector mode. After exposure, photoresist was developed using MIF 726 (MicroChemicals, Germany) developer for 25 seconds. Afterwards, photoresist was baked at 115ºC for 50 seconds. The next procedure was removal of aluminium from the exposed areas. This was done with a solution made of acetic acid, phosphoric acid and nitric acid. After this, the remained photoresist was removed with acetone.

In order to explore characteristics of lines fabricated in vector mode, Atomic Force Microscopy (AFM) measurement was performed. The structure on which AFM measurement was performed is marked as red square in Fig. 3. A 3D AFM scanning along the transition area between sputtered Al 1% Si and SiO_2 is shown in Fig. 4. Fig. 5 gives 2D image of the same structure. The profile of the transition (red line in Fig. 5) is shown in Fig. 6.

Thickness of sputtered Al 1% Si is estimated to be around 0.7 µm from Fig. 6 and surface roughness is around 73 nm, Fig 6.

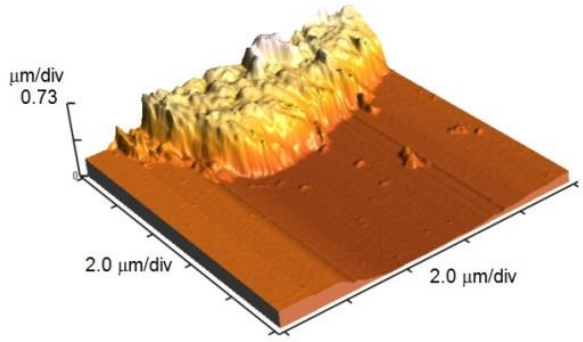

Fig. 4. 3D AFM picture of the obtained structure

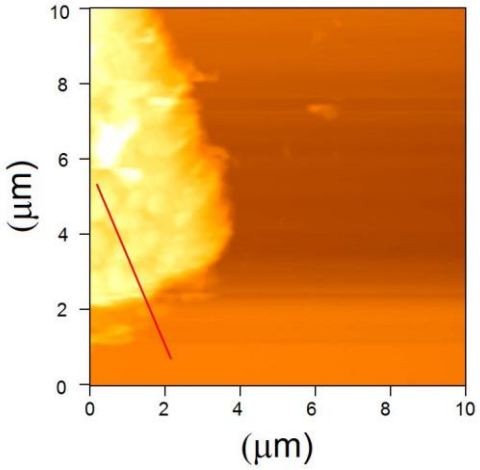

Fig. 5. 2D AFM image with the profile line marked red.

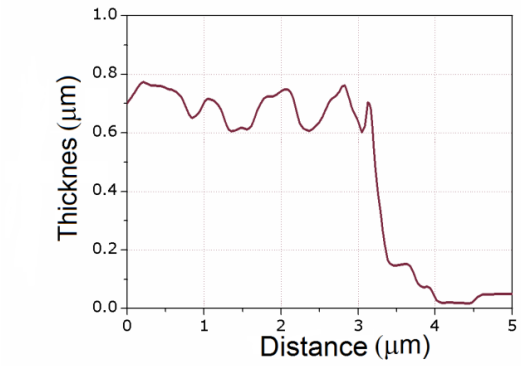

Fig. 6. profile of the characteristic line.

III. Analytical Model of Sensor Functionality

Under normal conditions gas is behaving as an electrical insulator. Under certain conditions gas can conduct electricity [8]. The flow of the electrical current through gases is known as electrical discharge. There are three different types of electrical discharge – Townsend (dark) discharge, glow discharge and arc discharge. These types can be distinguished by current-voltage characteristics.

For the functionality of this sensor, the region of interest

is Townsend discharge. In this region the applied voltage accelerates free ions and electrons so that certain number of them will reach the electrodes. The current is proportional to the applied voltage and gas acts as an Ohmic resistor. Further increasing of voltage allows all charged particles to reach the electrode and current enters the saturation. If the applied voltage is further increased, the current rapidly increases. This is a consequence of creating new ions in gas by collisions.

Ionization in this region is a consequence of three processes [9]:

-While moving toward anode electrons collide with gas particles and generate more electrons and ions;

-Positive ions moving toward the cathode collide with gas particles, ionize and also generate certain numbers of electrons and positive ions;

-Particles such as positive ions strike the cathode to emit secondary electrons.

Each of these processes is quantitatively characterized by three Townsend coefficients: α, β and γ respectively. Townsend coefficient α is the electron ionization coefficient for the volume of gas. If the number of accelerated electrons is n_{e0} and the gap between the electrodes is x then the number of produced electrons is [9]:

$$n_e = n_{e0}e^{\alpha x}, \tag{1}$$

and discharge current reaching the anode is [9]:

$$i_e = i_{e0}e^{\alpha x}. \tag{2}$$

Coefficient α depends on the mean free path of electrons, λ_e, and intensity of the electric field E. It can be calculated using equation [9]:

$$\alpha = \frac{1}{\lambda_e}\exp\left(-\frac{V_i}{E\lambda_e}\right), \tag{3}$$

where V_i is ionization energy of gas component.

Mean free path is the average distance travelled by particle between colliding. With approximation of the ideal gas state, mean free path can be calculated using equation [10]:

$$\lambda_e = \frac{kT}{\sqrt{2}\,p\pi d^2}, \tag{4}$$

where k is the Boltzmann constant, T is the gas temperature, p is the gas pressure and d is the effective diameter of the particle.

Equations (3) and (4) show that, for a specific gas α is a function of the gas pressure and the electric field intensity.

Coefficient β is a positive ion ionization coefficient. Required energy for positive ions to ionize neutral particles is thousands of electron volts. In a normal discharge process ions do not have this energy so a contribution of β is negligible [9].

Coefficient γ is the electrode surface ionization coefficient for positive ions. It shows how many electrons are emitted from the cathode when positive ion strikes it. If $n_0(e^{\alpha x}-1)$ positive ions strike a cathode, the number of electrons emitted from cathode will be $\gamma n_0(e^{\alpha x}-1)$. Coefficient γ is a function of cathode material and kinetic energy of impact ions. Ions must have enough energy to overcome the electron binding energy of cathode material. Given that the kinetic energy of ions is determined by the intensity of the electric field and gas pressure, one can tell that coefficient γ is a function of gas pressure, intensity of the electric field and cathode material. Coefficient γ can be calculated using Baragiola empirical equation [11]:

$$\gamma = 0.032(0.78V - 2\varphi), \tag{5}$$

or Hagstrum's semi empirical equation [11]:

$$\gamma = \frac{0.2(0.8V-2\varphi)}{\varepsilon_F}. \tag{6}$$

In both equations, V is the energy of incident ion, φ is the work function, and ε_F is the Fermi energy.

Total discharging current is [9]:

$$i_e = \frac{i_{e0}e^{\alpha x}}{1-\gamma(e^{\alpha x}-1)} \tag{7}$$

Total discharge current is a function of Townsend coefficients, thus, it is a function of pressure and intensity of electric field.

Total discharge current as a function of pressure was calculated for various values of the electric field intensity and for various gases. Total discharge current was calculated using (7). The work function of aluminium is 4.25 eV [12] so electrode surface ionization coefficient (γ) contribution is negligible for the considered voltages. Electron ionization coefficient was calculated using (3), and mean free path was calculated using (4).

Total discharge current versus pressure for argon and molecules of nitrogen and oxygen is shown in Fig. 7. Pressure range is between $1{\cdot}10^5$ Pa and $7{\cdot}10^5$ Pa. Ionization energies are 15.763 eV for argon [13], 12.0697 eV for oxygen [14] and 15.581 eV for nitrogen [15]. Kinetic diameters are 340 pm for argon [16], 346 pm for oxygen [17], and 364 pm for nitrogen [17].

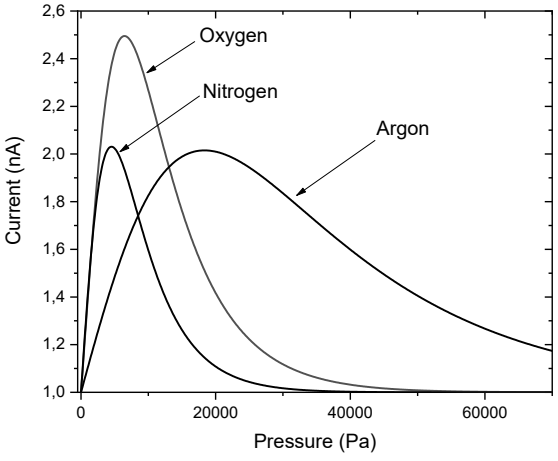

Fig. 7. Current versus pressure for O_2, N_2 and Ar for intensity of electric field of $1{\cdot}10^7$ V/m.

Total discharge current for various intensities of the electric field is shown in Fig. 8.

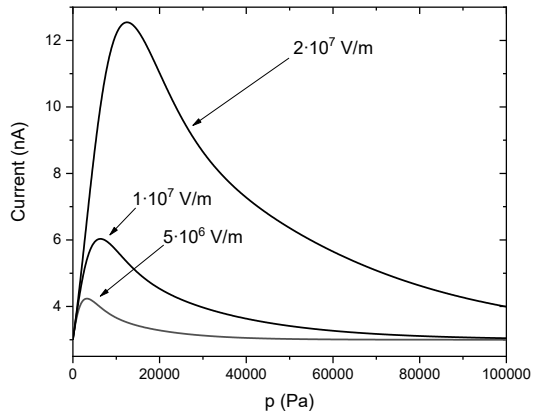

Fig. 8. Total discharge current versus pressure for different intensity of the electric field for Ar, O_2, and N_2 all together.

Influence of the intensity of the electric field (i.e. applied voltage) can be understood from the plot of total current vs. pressure for various intensities of electric field, Fig. 8.

Fig. 8. shows that current has maximum values on 2300 Pa, 4500 Pa and 9000 Pa for intensity of the electric field of $5{\cdot}10^6$ V/m, $1{\cdot}10^7$ V/m, and $2{\cdot}10^7$ V/m, respectively.

Applying different voltage on sensor pads can provide required pressure range.

Current in Fig. 7, and Fig. 8 is calculated for one pair of wedges (Fig. 2). In a single bunch there are 2110 pairs of wedges and in whole sensor, there are 9240 pairs of wedges, so current has to be multiplied by these factors.

IV. Proposal of the Experiment

Fig. 9 shows simplified scheme of measurement set-up.

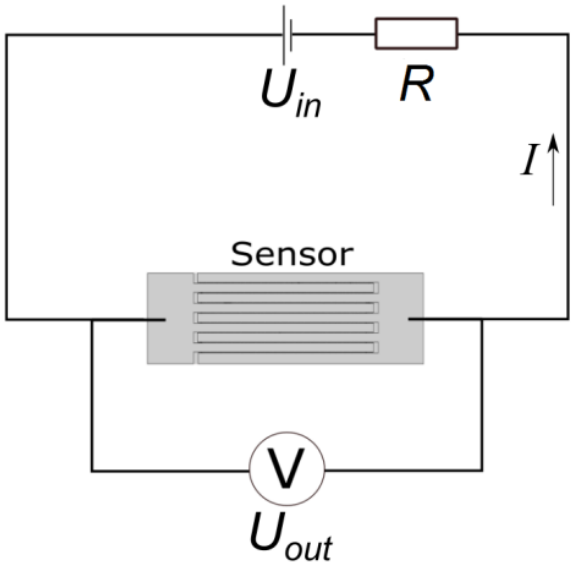

Fig. 9. Simplified scheme of the measurement principle.

Principle of operation can be understood from Fig. 9. Voltage is applied on pads of one bunch. If, for given voltage, gas pressure is above pressure upper limit for which gas between wedges is conductive there will be no current flow through a circuit (resistance of gas between opposite wedges is infinite) and output voltage will be the same as the input voltage, $U_{out} = U_{in}$. If the applied voltage is increased, or if the pressure is reduced, gas between wedges will become conductive and there will be current flow through the circuit. The output voltage will be lower and could be calculated using the equation:

$$U_{out} = U_{in} - IR, \tag{8}$$

where I is the current through the circuit and R is the resistance, Fig. 9. Current in a circuit is a total discharge current (7). Further reduction of the pressure will alter Townsend coefficients and change discharge current and, according to (8), the change in current will give different output voltage.

In the proposed design sensor consists out of four bunches identical with one on Fig. 9 (labelled as sensor). These bunches can be connected in parallel if the current in one bunch is not large enough to be detected.

Schematic for calibration of the sensor is shown in Fig. 10.

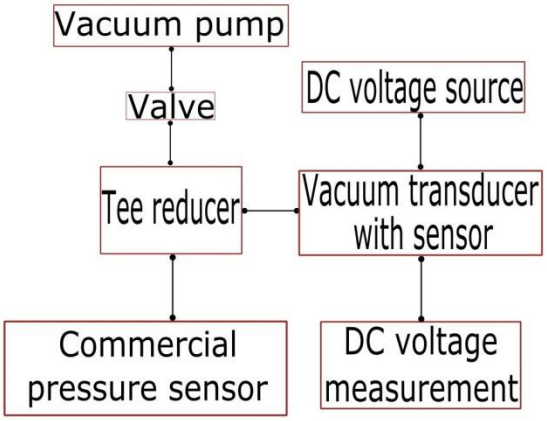

Fig. 10. Block scheme of sensor calibration experiment.

Calibration of the sensor could be done by a recording of the sensor voltage drop as a function of the pressure for a given intensity of the electric field. The pressure should be slowly reduced using a vacuum pump and control valve. The pressure value can be controlled by the commercial pressure sensor. Voltage drop should be measured for different pressure values using appropriate electronics. As a result, the voltage vs. pressure curve could be obtained which may serve as a calibration curve for the sensor.

V. Conclusion

Design and analytical model for planar pressure sensor have been presented. It was shown that it is feasible to fabricate the desired structure using direct laser writing. Calculations based on the presented analytical model have been done for different gases and for various intensities of the electric field. Calculations showed that measurable current-dependence of pressure can be accomplished for a wide range of pressure by applying different voltages. The proposed sensor design seems to be a competitive microscopic device for measuring pressure in a wide vacuum range.

***Abstract*— In this paper, we present and analyze etching of parallelogram patterns in the masking layer on a (100) silicon in 25 wt % TMAH water solution at the temperature of 80 ℃. Sides of parallelogram islands in the masking layer are designed along <n10> and <100> crystallographic directions. A 3D simulation of the profile evolution from these patterns during etching of silicon using the level set method is also presented. We determined all crystallographic planes that appear during etching in the experiment and obtained simulated etching profiles of these 3D structures. A good agreement between dominant crystallographic planes through experiments and simulations is obtained.**

***Index Terms*—silicon; wet etching; TMAH; simulation; level set method.**

I. Introduction

Because of its advantages to other etchants (high selectivity to thermal oxide, very smooth etching surface, integrated circuits process compatibility), wet etching of a (100) silicon substrate in tetramethylammonium hydroxide (TMAH) water solution was intensively studied [1-26]. Etched silicon shapes are limited by the mask pattern designs and the etching anisotropy of TMAH water solution. Because of the differences in etch rates [2-8] during anisotropic wet etching some crystallographic planes will appear, while others will disappear. The most used etching patterns in the masking layer in the fabrication of various sensors and actuators were rectangular patterns with sides along <110> and <100> crystallographic directions. In the previous studies of silicon wet etching [1-26], processes were conducted using various etching solutions of TMAH at different temperatures and silicon wafers of various crystallographic orientations. Etching of square patterns with sides along <100> crystallographic directions was analyzed in [9,25]. Etching of octagonal patterns with sides along <210>, <310> and <410> crystallographic directions was discussed in [9] for TMAH water solutions. In our previous paper [25], we studied silicon etching of square and circle patterns in the masking layer when 25 wt % TMAH water solution is used at the temperature of 80 ℃. The sides of square patterns in the masking layer were designed along predetermined <n10> crystallographic directions. Authors in [26] explored etching of a (110) silicon using parallelogram patterns with sides along <110> and <210> crystallographic directions.

This paper presents our further work on a (100) silicon etching in 25 wt % TMAH water solution at the temperature of 80 ℃. For the first time etching of parallelogram patterns in the masking layer with sides that are designed along determined crystallographic directions <n10> (1<n<10) and <100> is analyzed. A 3D simulation of the profile evolution from these patterns islands during etching of silicon based on the level set method is presented. The level set method for evolving interfaces belongs to the geometric type of methods, and it is specially designed for profiles that can develop sharp corners, change of topology and undergo orders of magnitude changes in speed. All simulations are performed using a three-dimensional (3D) anisotropic etching simulator based on the sparse field method for solving the level set equations, described in our previous publications [27-33]. Pictures of the simulated etching profiles are rendered by Paraview visualization package [34]. We presented the simulated etching profiles and SEM micrographs to demonstrate all exposed crystallographic planes. Our aim is to observe and analyze the appearance of crystallographic planes and verify agreement of simulation with experimental results. Knowing the evolution of crystallographic planes during etching enables easy fabrication of various 3D silicon structures that can be used in the design of sensors and actuators.

surfaces and 1-5 Ωcm resistivity have been used. Anisotropic etching has been done in pure TMAH 25 wt. % water solution (Merck). The etching temperature was 80 ℃. Wafers were standard cleaned and covered with SiO_2 thermally grown at 1100 ^{0}C in an oxygen ambient saturated with water vapour (at least 1 μm thick). SiO_2 was etched in BHF in a photolithographic process in order to define parallelogram patterns along determined crystallographic directions. Again, wafers were subjected to standard cleaning procedure and were dipped before etching for 30 s in HF (10 %) to remove native SiO_2 followed by rinsing in deionized water. Etching of whole 3" wafer was carried out in a thermostated glass vessel containing about 0.8 dm^3 of the solution with electronic temperature controller stabilizing temperature within ±0.5 ℃. The vessel was on the top of a hot plate and closed with a teflon lid that included a water-cooled condenser to minimize evaporation during etching. The wafer was oriented vertically in a teflon basket inside the glass vessel. Throughout the process, the solution was electromagnetically stirred with a velocity of 300 rpm. After reaching the desired depth, the wafer was rinsed in deionized water and dried with nitrogen.

III. RESULTS AND DISCUSSION

Parallelogram patterns in the masking layer are designed with sides that are along determined crystallographic directions <n10> (1<n<10) and <100>. The acute corners of islands in the masking layer formed by <n10> and <100> crystallographic directions are larger than 45^0 and smaller than 90^0. The values of acute corners are given in Table 1. Different 3D shapes are obtained during etching of silicon in 25 wt %. In the cases of n<7 during etching initial acute angles are split into two angles in the masking layer. In the case of n=2, they are acute and obtuse angles. In the case of n=3, they are right and obtuse angles. In other cases, we have two obtuse angles. The sidewalls of the first convex corners angle are defined only by {n11} and {311}-{301} (or {401}-{203}) families at the beginning of etching [25], as shown in Fig. 1-3. This is similar to the etching of square patterns in the masking layer with sides along <n10> crystallographic directions [25]. The sides of obtuse convex corners angles are defined by {100} and {311} families at the beginning of etching. In the cases of 6<n<10 during etching initial acute angles are split in three obtuse angles in the masking layer The sidewalls of the central convex corners angles are defined by two planes of {311} families at the beginning of etching [25], as shown in Fig. 3-4. This is similar to the etching of square pattern in the masking layer with sides along <100> crystallographic directions [25]. The sidewalls of two other obtuse convex corners angles are defined by {100} and {311} families or {n11} and {311}-{301} (or {401}-{203}) families. The etch depth in Fig. 1-4 is 55 μm. Appearance of {301} families is hard to observe in the simulated etching profiles. These planes have smaller surface areas than the dominant ones. The planes obtained in the simulation are more round and the edges of the convex corners tend to soften [12-13,25].

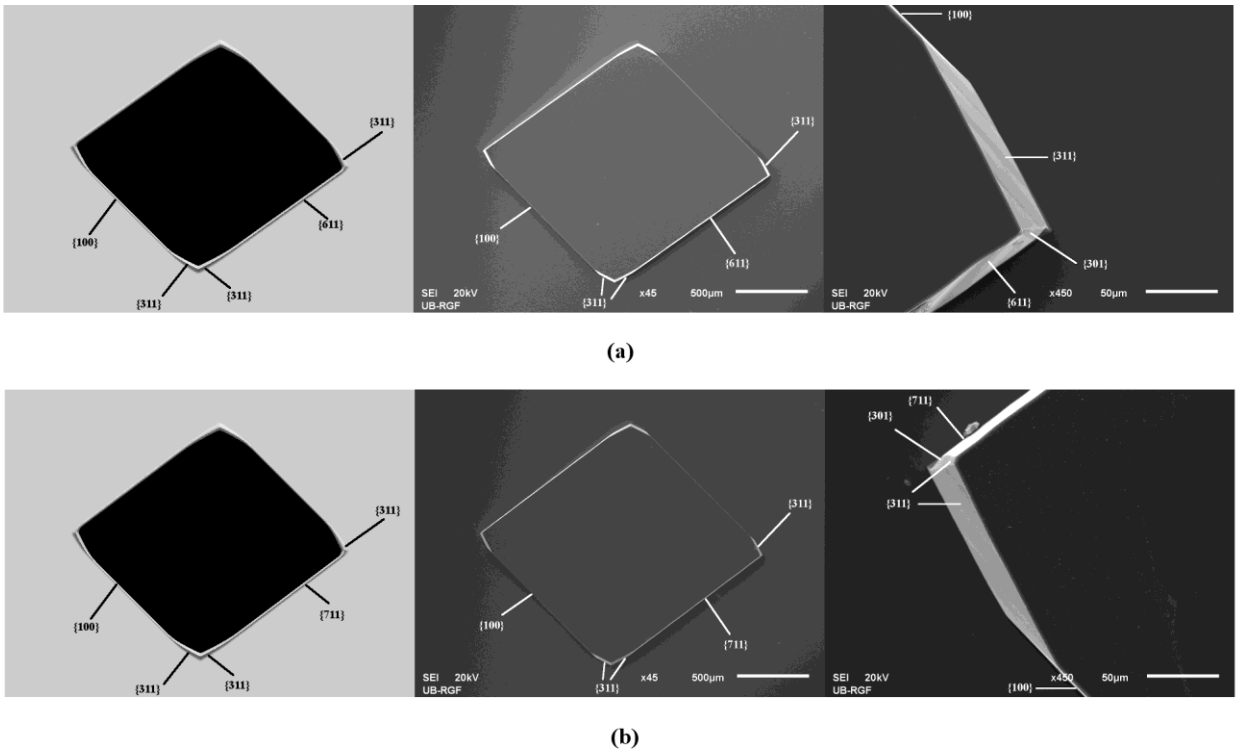

Fig. 3. Simulated etching profiles and SEM micrographs of the etched parallelogram patterns with sides along <100> and: (a) <610> directions; (b) <710> directions. Enlarged details of etched acute angles in the masking layer in both cases.

TABLE I
THE VALUES OF ACUTE ANGLES OF THE PARALLELOGRAMS

Crystallographic direction <n10>	Acute angle [^{o}]
<210>	63.4
<310>	71.6
<410>	76
<510>	78.7
<610>	80.5
<710>	81.9
<810>	82.9
<910>	83.7

The etching of island obtuse corners in the masking layer is the same for all cases except n=2, as shown in figures 1-4. During etching initial obtuse angles are split into three obtuse angles in the masking layer. The sidewalls of the first obtuse angle are defined by {311} and {n11} planes. The sidewalls of the second obtuse angle are defined by two planes of {311} family. This is similar to etching of square pattern in the masking layer with the sides along <100> crystallographic directions [25]. The sidewalls of the third obtuse angle are defined by {311} and {100} planes. For the case of n=2, the obtuse convex corner split only into two obtuse angles. The sidewalls of the first obtuse angle are defined by {311} and {211} planes. The second obtuse angle is defined by planes of {311} and {100} families.

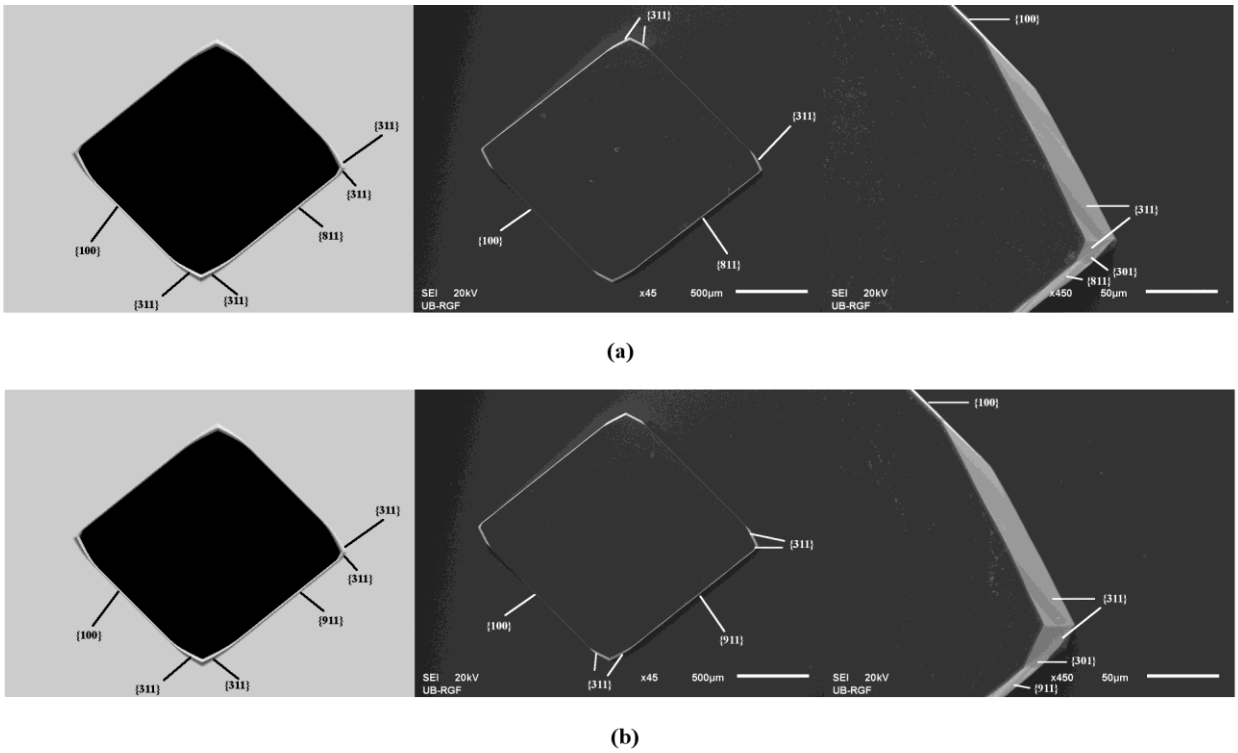

Fig. 4. Simulated etching profiles and SEM micrographs of the etched parallelogram patterns with sides along <100> and: (a) <810> directions; (b) <910> directions. Enlarged details of etched acute angles in the masking layer in both cases.

As etching continues sides planes of {311} family from the nearby convex corners become dominant and planes of {n11} (n>2) and {100} families disappear. The obtained shape is a truncated pyramid with the sidewalls defined by {311} and {301} families. The base of the pyramid in the masking layer is parallelogram with the sides along <310> crystallographic directions. In the case of n=2, the sidewalls are defined by {211}, {311} and {301} families. The base of the pyramid in the masking layer is parallelogram with sides along <310> and <210> crystallographic directions.

IV. CONCLUSION

In this paper, we studied silicon etching of parallelogram patterns in the masking layer in 25 wt % TMAH water solution at the temperature of 80 ℃. The sides of parallelogram islands were designed along <n10> and <100> crystallographic directions. We analyze the etching of islands in the masking layer using both the experiments and the simulations. All the crystallographic planes that appear during etching of silicon structures are determined. A good

agreement between dominant crystallographic planes through experiments and simulations is obtained. A comprehensive insight into the evolution of parallelogram patterns for different crystallographic directions can provide new ideas for the successful mask design of silicon microdevices.

Reversed ellipsoidal troughs sculpted in plasmonic multilayer nanomembranes

Marko Obradov, Zoran Jakšić, *Senior Member, IEEE* , Ivana Mladenović, Dragan Tanasković, Dana Vasiljević Radović

***Abstract*—Nanomembranes represent a versatile novel building block in micro- and nanoelectromechanical systems, inspired by biological cell membranes. If built as quasi-2D multilayer metal-dielectric nanocomposites, they represent a natural choice for the use in plasmonics and optical metamaterials, ensuring a new degree of design freedom and thus a number of new applications.**

In this contribution we consider surface sculpting of two types of three-layer nanomembranes – metal-insulator-metal (MIM) and insulator-metal-insulator (IMI) structures. The geometry we analyze represents troughs with ellipsoidal profiles sculpted in the multilayer nanomembranes, simultaneously acting as plasmonic waveguides and ensuring tailoring of frequency dispersion of the plasmonic nanomembranes.

We determine frequency dispersions of the scattering parameters for the simulated nanomembranes, as well as the spatial ditribution of the optical near fields in and around them, both evanescent (plasmon-polariton based) and propagating. To this purpose we utilize finite element method simulations.

The obtained results show that our IMI structures exhibit a behavior similar to that of the EOT arrays, resulting in optical transparency of the structure for resonant plasmonic modes. On the other hand, MIM structures offer an excellent confinement of electromagnetic radiation within the dielectric layer. We conclude that both MIM and IMI channels allow for additional degrees of freedom in customization the nanomembrane evanescent fields, making a way to numerous potential applications.

I. Introduction

SYNTHETIC NANOMEMBRANES are artificial, biologically inspired, freestanding, self-supported structures resembling bilipid cell membranes but offering a much wider choice of materials, surface patterns and profiles [1]. They are quasi-2D structures, meaning that their aspect ratios can be huge – their widths and lengths can be even six to seven orders of magnitude larger than their thickness [2]. The possibility to functionalize nanomembranes [3] opens a pathway towards myriads of pratical applications. One of the possible approaches to such functionalization is 3D surface sculpting of nanomembranes, as proposed in [4] and described in more details in [3].

Plasmonic nanomembranes represent mono- or multilayer structures that can be described as 1D plasmonic crystals [5]. They consist of one or more of conductive materials whose electron dynamics is described by Drude model, with possible incorporation of dielectric(s). Freestanding plasmonic nanomembranes represent a new building block in photonics, subwavelength optics and plasmonics and they can be as simple as a nanometer-thin metallic sheath surrounded by dielectric (air). The subwavelength thickness of nanomembranes together with their electromagnetic symmetry ensures coupling of surface plasmons polaritons (SPP) from their both sides, resulting in the appearance of the SPP with extremely large propagation paths. Such SPPs are known as long range (LR) SPPs [6].

Similarly to metamaterials and nanoplasmonic structures, plasmonic nanomembranes exhibit peculiar phenomena, many of which are not met in natural materials, including extremely high values of refractive index, very low and zero values, as well as negative refractive index. It may be safely said that plasmonic nanomembranes enable one to manipulate evanescent near fields, practically making it possible to tailor light at will. A whole new field of electromagnetic optics developed from these properties – the transformation optics [7, 8]. This on the other hand ensures various applications like ultrasensitive chemical and biological sensors with single-molecule sensitivity, superlenses and hyperlenses, superabsorbers, superconcentrators, invisibility shields (cloaking devices), all-optical integrated circuits, and many more [9].

Since SPPs exist outside of light cone coupling of incident light to these modes requires some form of impedance matching between the two. The use of diffractive gratings for

this purpose ensures not only coupling between propagating modes and SPPs but also allows tailoring of dispersive properties by changing the geometrical properties of the grating. Plasmonic modes of these structures are characterized by high field localization within subwavelength openings.

The analysis of plasmonic nanomembranes integrated with diffractive couplers is of large practical interest since it gives us data on the optimum ways of coupling between evanescent modes of LR SPP and propagating light. More generally, it ensures tailoring of frequency dispersion including the determination of modes that simultaneously exist within the light cone an outside of it.

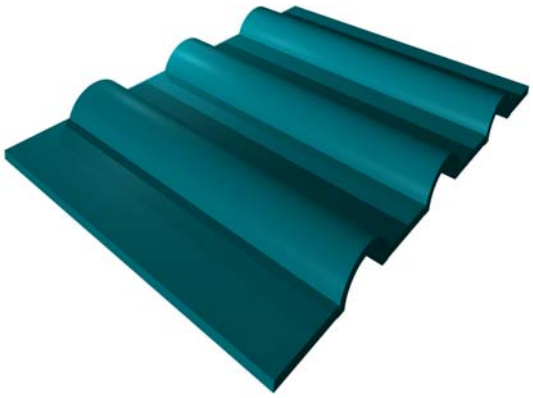

Fig. 1. General presentation of a sculpted nanomembrane with a diffractive grating formed by an array of reversed troughs with ellipsoidal profiles.

In this contribution we analyze a specific geometry of plasmonic nanomembrane integrated with a diffractive grating. The case we analyze is represented in Fig. 1. It shows troughs with ellipsoidal cross-section sculpted in the surface of a nanomembrane. Contrary to [10], here we analyze both IMI and MIM multilayer nanomembranes. To this purpose we utilize COMSOL Multiphysics RF module. We analyze a freestanding plasmonic nanomembrane with embedded diffractive grating. The unit cell of our proposed structure is shown in Fig. 2.

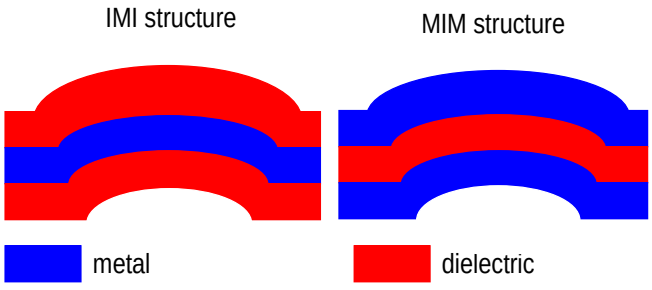

Fig. 2. Cross section view of unit cell of a corrugated multilayered freestanding nanomembrane. Insulator-metal-insulator (IMI) structure (left) and metal-insulator-metal (MIM) structure (right).

II. THEORY

For most conductors based on free electrons their electromagnetic properties in the optical range are well described by lossy extended Drude model. The frequency dispersion of ther complex relative dielectric permittivity $\varepsilon(\omega)$ is given by the following relation [11]:

$$\varepsilon(\omega) = \varepsilon_\infty - \frac{\omega_p^{\ 2}}{\omega^2 + i\gamma\omega}, \tag{1}$$

ε_∞ is the asymptotic dielectric permittivity and $\gamma = 1/\tau$ is the characteristic frequency related to the damping of electron oscillations due to collisions, where τ is the relaxation time of the electron gas and plasma frequency is determined by the concentration of free carriers

$$\omega_p = \frac{ne^2}{m^*\varepsilon_0} \tag{2}$$

where n is electron concentration, e is the free electron charge ($1.6\cdot10^{-19}$ C), ε_0 is the dielectric permittivity of the vacuum ($8.854\cdot10^{-12}$ F/m), and m^* is the effective mass of electrons.

Dispersion relation of SPP propagating on a metal-dielectric interface is given by :

$$k_{spp} = k_0\sqrt{\frac{\varepsilon_d\varepsilon_m}{(\varepsilon_d + \varepsilon_m)}} \tag{3}$$

where $k_0=2\pi/\lambda$ is the wavevector in vacuum, ε_d is the relative permittivity of dielectric and ε_m is the relative permittivity of metal described by Drude model (1).

Coupling between propagating waves and SPP bound on metal-dielectric interface can be achieved by different impedance-matching techniques. By embedding diffractive gratings in the metal-dielectric interface, the impedance matching between SPP and propagating waves is achieved through the diffracted modes of the grating. The wave vector of the diffracted mode is determined by the grating constant a:

$$k_d = \pm m\frac{2\pi}{a} \tag{4}$$

where m is an integer. Coupling of the propagating wave with the SPP occurs when the following condition is met:

$$\vec{k}_{spp} = \vec{k}_d + \vec{k}_p \tag{5}$$

where k_p is the wavevector of the wave propagating in-plane, parallel to the interface

$$k_p = \frac{\omega}{c}\sin\theta \tag{6}$$

where c is the speed of light in the medium above the plasmonic surface, ω is the angular frequency and θ is the incident angle of the propagating modes.

For multilayered metal-dielectric structures SPPs on multiple interfaces can couple, leading to the splitting of resonant states, starting with the even and odd states with only two interfaces and expanding into optical bands as the number of layers (interfaces) increases.

III. Results and Discussion

We examined optical properties of the freestanding corrugated IMI and MIM nanomembranes as shown in Fig. 1. using RF module of Comsol Multiphysics software package. The width of the entire unit cell is a = 1000 nm, which is also the periodicity of the embedded diffractive grating. Embedded curvatures of the reversed troughs are modeled as ellipses with 100 nm and 200 nm semi axes (bottom curvature) and 250 nm and 350 nm semi axes (top curvature). Individual metal and dielectric layers are 50 nm thick. The structure is surrounded by air. Metal is chosen to be nickel with Drude model parameters taken from the literature [12] and dielectric is polymer with a refractive index n=1.4.

Our finite element simulations determine the spatial field distributions as well as the frequency dispersion of the transmission and reflection coefficient for TM plane waves incident on the structure from various angles. Two parallel ports, one active and one passive were added above and below the structure to simulate the flow of optical radiation through the simulation domain, with light entering the domain from the top. Floquet boundary conditions are applied to the edges of the unit cell to simulate the periodicity of the structure. The parametric sweep of the wavelengths and incident angles was used to determine the dispersive properties of the scattering parameters and the spatial distributions of the electromagnetic field.

The dispersive properties of the IMI structure are shown in Fig. 3. It is observed in Fig. 3 that IMI structure behaves similarly to extraordinary optical transmission (EOT) arrays, exhibiting increased transparency due to surface plasmonic modes. For normal incidence the IMI structure roughly supports two narrow transparency bands as shown in Fig. 3a with sharp resonant peak at 610 nm. For oblique incidence shown in Fig. 3b and Fig. 3c for 30º and 60º incident angles the structure exhibits a rich modal behavior with a multitude of narrow resonant peaks, especially for the 30º incident angle.

Spatial field distributions for IMI structure at some of the resonant wavelengths are shown in Fig.4-7. Presented field distributions illustrate exceptional capabilities of IMI structure in tailoring spectral and spatial near field enhancement due to plasmonic resonance. Fig. 4 and 5 present two modes for normal incidence with complementary spatial distributions each stemming from different substructure of the complex IMI structure. The first mode at 580 nm stems from the core-shell substructure (reversed troughs of the multilayer nanomembrane) with enhanced scattering on both sides of the membrane.

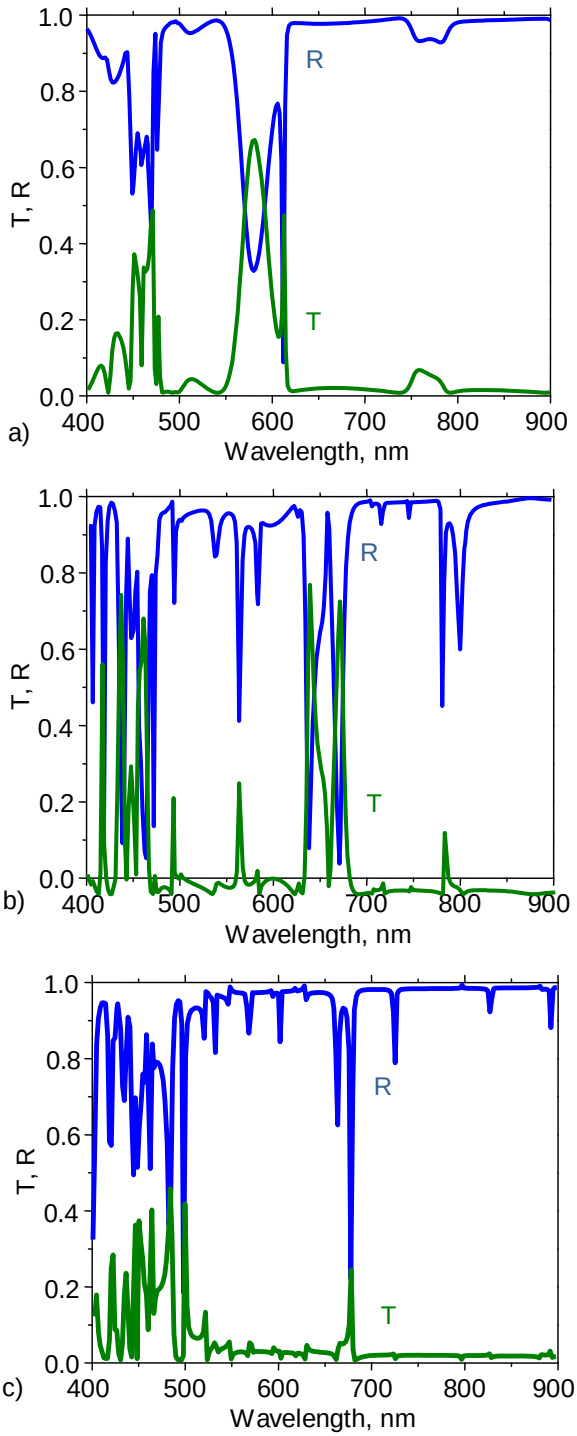

Fig. 3. Dispersive properties of IMI freestanding nanomembrane for different incident angles: a) normal incidence; b) 30º incident angle; c) 60º incident angle. Green: transmission coefficient; blue: reflection coefficient.

The second mode at 610 nm is bound to the surface at the planar part of the structure. Fig. 6 shows that near field enhancement can be localized on the back side of the structure by changing the incident angle. Fig. 7 shows hybridization of the surface modes from different parts of the structure resulting in high field localization spread across the entire structure.

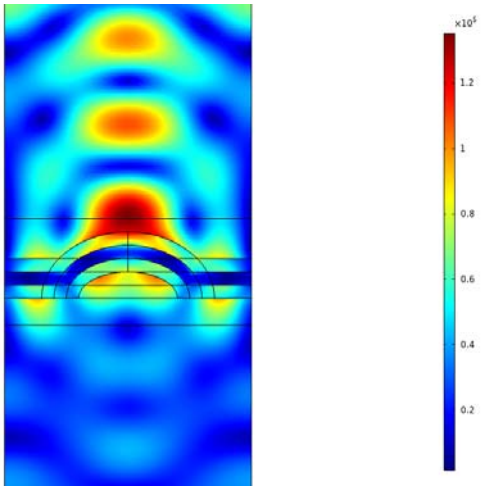

Fig. 4 IMI freestanding nanomembrane, electric field spatial distribution for normal incidence at 580 nm.

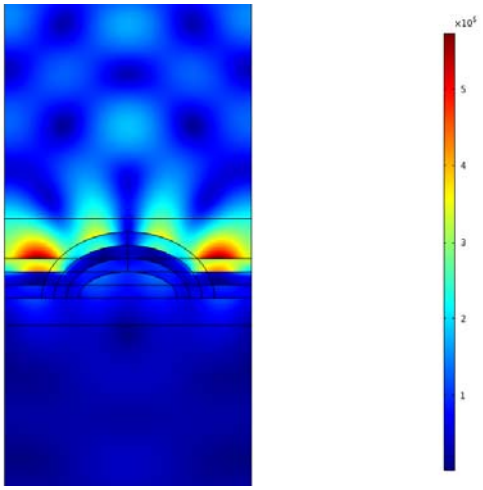

Fig. 5 IMI freestanding nanomembrane, electric field spatial distribution for normal incidence at 610 nm.

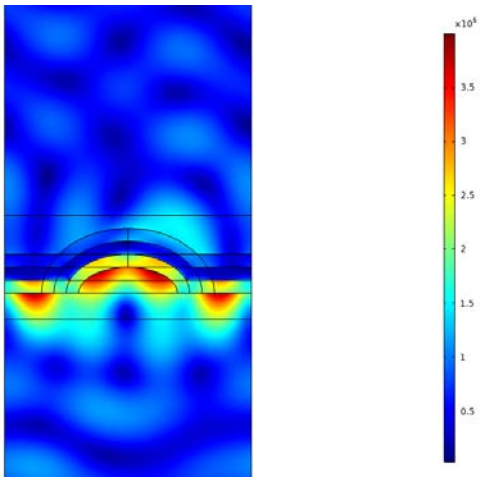

Fig. 6. IMI freestanding nanomembrane, electric field spatial distribution for 30º incident angle at 565 nm.

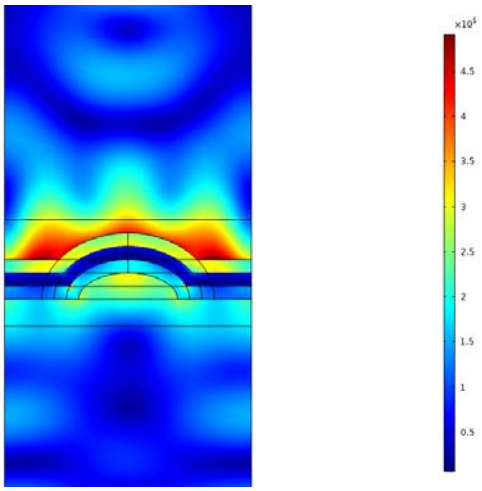

Fig. 7. IMI freestanding nanomembrane, electric field spatial distribution for 60º incident angle at 665 nm.

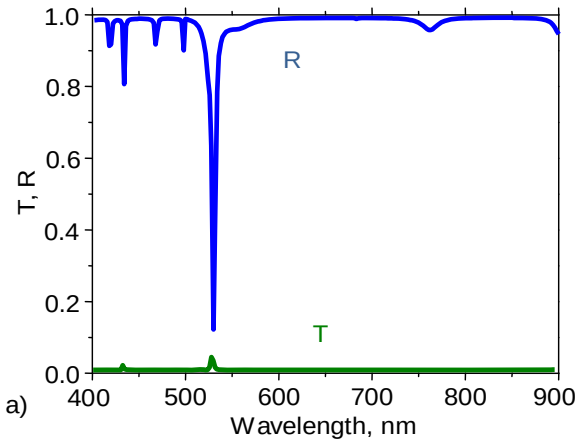
The dispersive properties of the MIM structure are shown in Fig. 8. Unlike the IMI structure, the MIM structure is highly opaque, denoting that the part of the energy of the propagating wave that isn't being reflected is being funneled into bound surface modes when plasmonic resonance occurs. For normal incidence (Fig. 8a) coupling between the propagating waves and the bound modes is possible due to the corrugated structure of the nanomembrane resulting in a sharp resonant reflection dip at 530 nm. Due to strong coupling between the propagating and the bound modes a high field localization is achieved within the dielectric layer of the MIM structure, as shown in Fig. 9. The number of the bound surface modes that the structure can support increases for oblique incidences, as shown in Fig. 8b and Fig. 8c. The field distribution for another mode with strong coupling for 30º incidence angle at 535 nm is shown in Fig.10. For this mode light localization is moved from the central dielectric layer to the surface of the membrane, allowing again for tailoring of field localization by changing the angle of incidence. Fig. 11 shows a situation similar to the one in Fig. 9 but with much weaker coupling between the propagating and the bound modes resulting in weaker near field enhancement, while retaining the spatial distribution.



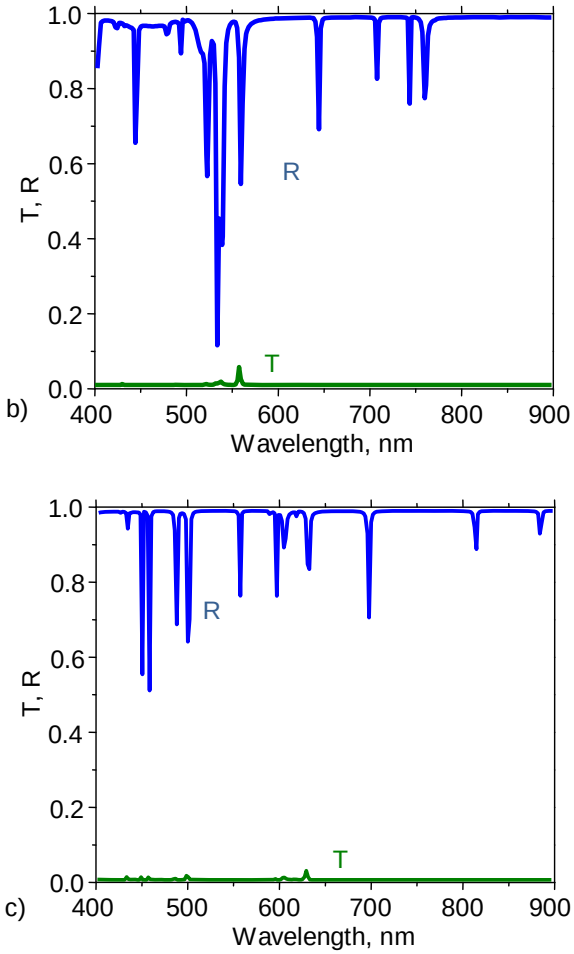


Fig. 8. Dispersive properties of MIM freestanding nanomembrane for different incident angles: a) normal incidence; b) 30º incident angle; c) 60º incident angle. Green: transmission coefficient; blue: reflection coefficient.

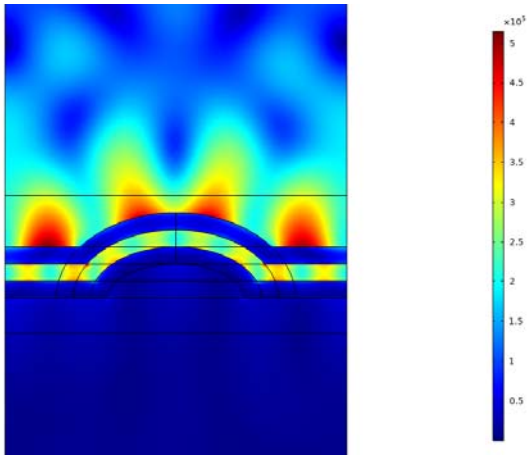

Fig. 10 MIM freestanding nanomembrane, electric field spatial distribution for 30º incident angle at 535 nm.

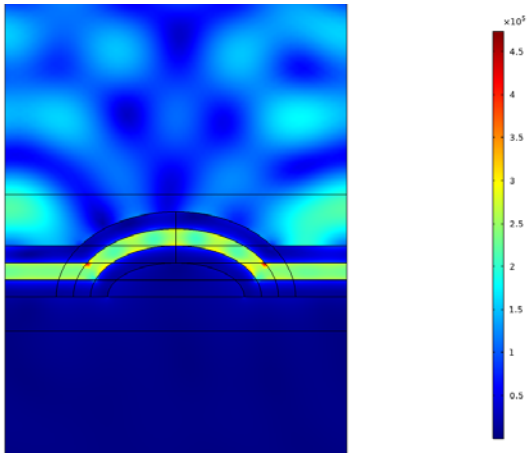

Fig. 11. MIM freestanding nanomembrane, electric field spatial distribution for 60º incident angle at 500 nm.

IV. Conclusion

We analyzed optical properties of corrugated IMI and MIM freestanding nanomembranes using FEM simulation. We have shown that our IMI structure exhibits a behavior similar to that of the EOT arrays, resulting in optical transparency of the structure for resonant plasmonic modes. Together with a rich modal behavior and an angular selectivity of the field spatial distributions, this allows for additional degrees of freedom in customizing the nanomembrane evanescent fields. The MIM structure offers excellent confinement of electromagnetic radiation within the dielectric layer and allows for fine tuning of both the near field enhancement and its spatial distribution by adjusting the angle of incidence.

Solution-processed Silver Nanowires as Transparent Electrodes in Solar Cells

Vuk Radmilović

Abstract— **As with all optoelectronic devices like displays, touch panels, or light emitting diodes (LED), solar cells require materials with high electrical conductivity and optical transparency for creating high performance transparent electrodes. Conventional materials used for this purpose have numerous drawbacks mostly regarding demanding and expensive processing methods which is why alternatives are explored. Such are silver nanowires, easily synthesized and processed very cost effective nanostructures. Our work consisted of utilizing silver nanowires as transparent electrodes in two types of solar cells - conventional silicon-based and new generation flexible organic-based. Results show that silver nanowire based transparent electrodes exhibit optoelectronic properties comparable to conventional transparent electrodes and hence, solar cells utilizing silver nanowire based transparent electrodes exhibit competitive power conversion efficiencies to ones utilizing conventional materials.**

Index Terms—**Silver Nanowires (AgNW), Transparent Electrodes, Solar Cells, Photovoltaics, Printed Electronics.**

I. Introduction

It is fairly obvious that, as we proceed into the 21st century one of the main concerns of the human race is providing sustainable energy for ~7.7 billion people on Earth. Keeping in mind the amount of reserves of finite energy sources like coal, petroleum, natural gas and uranium, along with their environmental drawbacks such as atmosphere pollution and radiation, drastic measures have to be taken in order to balance energy production and prevention of environmental disasters like nuclear meltdowns or the greenhouse effect. These drastic measures include completely switching to renewable and environmentally acceptable energy sources. Among these sources, the sun i.e. solar energy stands out as it has a potential of nearly 1.9×10^8 TWh/y [1], more than 200 times the amount of all renewable resources combined. Since the latest data shows that the total global energy consumption is around 20 TWh and is projected to be over 40 TWh by 2050 [1], it is clear that solar energy is predominant choice to make that is both large enough and environmentally acceptable for the planet which is why there is a growing global interest in research of solar cells or photovoltaics, through which solar energy is converted into electricity.

What is the core of the phenomenon of conversion of solar energy into electricity? Solar cells are comprised of semiconductors, materials that posses weakly bonded electrons which occupy the valence energy band. If an energy greater than the band gap energy (gap between valence and conduction bands) is applied to a valence electron, the bonds are broken and the electron is free to move to a higher energy band - the conduction band. Source of this energy is supplied by quanta of light - photons. When the electrons move to the conduction band, a selective contact (n-type electrode) collects such electrons and sends them to the external circuit, where electrons lose their energy (through work) and are restored to the solar cell by another contact (p-type electrode) which returns them to the valence band and their initial energy. This is called the photovoltaic effect. Three generations of solar cells have been developed so far. Unlike the silicon (Si) wafer-based first generation cells and thin film based second generation cells, third-generation technology utilizes far less demanding and less expensive processing methods. Organic compounds like polymers, used in third generation organic solar cells (OSCs) posses the potential of having their properties tailored through molecular design and synthesis yielding desirable intrinsic properties like low weight, flexibility and high optical transparency. Unfortunately, the disadvantages of this technology still include low efficiency (due to low dielectric constant of polymers, absence of a crystal lattice and spectral mismatch between solar spectrum and organic materials) and short lifetimes (conductive polymers degrade in the light)[2]. However, even with these disadvantages, this technology exhibits huge potential as third generation of solar cells can be processed on flexible substrates by various simple printing methods using novel materials in very small quantities. This is particularly attractive as the global market for printed electronics is expected to surpass 44 billion dollars in the coming years, 7.7 out of which will be from solar cell technologies [3].

In solar cell architecture, besides the active layers where the photoconversion actually occurs, electrode layers (selective contacts, as mentioned) serve a very important function – they form differences in potentials which help split charge carriers during photoconversion and guide them, thereby forming electron current. Indium tin oxide (ITO) is the most frequently used material for electrodes in solar cells due to its optimal high optical transparency and low electrical sheet resistance combination. Despite ITO's beneficial properties, needed for transparent electrodes (TE), alternative materials need to be explored due to numerous drawbacks such as high price of indium, it chemical instability, brittleness, demanding processing procedures etc. One of the most promising candidates to replace ITO are NW networks, specifically AgNW networks, due to their excellent optoelectronic properties, second only to ITO and their ease of synthesis and

Vuk Radmilović is with the Faculty of Technology and Metallurgy, University of Belgrade, 4 Karnegijeva, 11020 Belgrade, Serbia (e-mail: vukradmilovic@tmf.bg.ac.rs).

processability [2]. This was the motivation for the work done by our group and our goal was to utilize solution-processed silver nanowires in both, first generation solar cells i.e. crystalline silicon based solar cells, as well as third generation solar cells i.e. tandem bulk heterojunction (BHJ) OSCs, where multiple polymer nanocomposite active layers are stacked atop of each other in order to increase absorption bands and carrier mobility in the device as a whole.

II. The Method

A. AgNWs in Si-based Solar Cells

For application as TE in Si-based solar cells, AgNWs were synthesized in house. For AgNW synthesis, the polyol reduction method [4] was used where ethylene glycol (EG) was utilized as the reducing agent and solvent. By adding EG to the precursor silver nitrate ($AgNO_3$), silver ions (Ag^+) reduce to nuclei (Ag atoms), which are unstable. As these nuclei grow, they form larger clusters, fluctuations disappear and they adopt the role of seeds from which various structures can be grown. These seeds can be multiply twinned (as in the case of AgNWs), single twinned or single crystalline. Formation of aggregates is fuelled by mechanisms of surface diffusion and energy minimization, which is why controlling the kinetics of each step can lead to the control of nanocrystal morphology. In the synthesis of AgNWs, surfactant used was polyvinylpyrrolidone (PVP), a polymer which controls the shape of AgNWs during synthesis by preventing coalescence of nuclei during initial growth. It binds to {100} NW facets, passivating them, enabling growth of only {111} facets in the [110] direction resulting in a one-dimensional (1D) NW structure. By analyzing multiple scanning electron micrographs (SEM) of the NW network, it was deduced that diameter size distribution of AgNWs is characterized by relative monodispersity with an average diameter of ~130nm [2].

After synthesis, AgNWs were annealed at 250°C for 3min in order to reduce electrical resistance of the network as resistance at NWs junctions is much higher than in the NWs themselves. Thermal activation occurs at relatively low T (well below T_m) which leads to surface diffusion of Ag atoms, solid-state wetting and the formation of welded NW junctions [2]. Decrease of the total free energy of the junction is the driving force for the local enhanced diffusion [5,6]. This process is essentially sintering. After local sintering at the AgNW junctions, electrical resistance starts to decrease as PVP encapsulating organic layers starts to decompose [7]. After annealing, the sample was coated with a layer of aluminum doped zinc oxide (AZO) by atomic layer deposition (ALD), which produced a uniform thickness coating of ~100nm. AZO was chosen because it tightens junctions and fills empty space between NWs enhancing conductivity, although resulting in slightly poorer optical transmittance [2].

Solar cell device fabrication was prepared with a diffused p–n junction i.e. boron doped Si wafer pieces (p-type) were used which were doped by phosphorous (n-type) containing spin-on-glass. This was achieved by spin coating and subsequent annealing for dopant diffusion. Finally, after spin-on-glass removal, various top electrodes were deposited [4].

The aim of this work was to characterize the microstructure of AgNWs/AZO nanocomposite and subsequently to develop a new nanocomposite material superior to other electrode solutions such as pristine AZO, Ag grid, or various combinations of the four materials mentioned.

B. AgNWs in BHJ OSCs

For application as TE in tandem BHJ OSCs, AgNWs dispersion (ClearOhm ink) was received from Cambrios Technologies Corporation, with an average AgNW diameter of ~30 nm. Solar cell device fabrication was prepared as follows: for the fully printed cells, all layers have been deposited from ink (solution/suspension) on glass and PET substrates by doctor blading in ambient atmosphere. The layers were processed on substrate and dried for solvent evaporation after each deposition, in the following order: PEDOT:PSS, opaque Ag, PEDOT:PSS, GEN-2:PCBM, ZnO, PEDOT:PSS ,pDPP5T-2:PCBM, ZnO, AgNWs. The role of the first PEDOT:PSS layer is to enhance the adhesion of the reflective Ag to the substrate. The role of the opaque Ag layer is that of a highly reflective electrode for allowing multiple passages of photons into the active layers in order for photocurrent generation increase. The role of the second PEDOT:PSS layer is to act as an electron blocking layer. The GEN-2:PCBM is the first active nanocomposite layer or BHJ, in which actual photoconversion occurs, where GEN-2 (Merck) is the polymer matrix and electron donor (1.76 eV bandgap) while PCBM is [6,6]-phenyl-C61-butyric acid methyl ester, a the fullerene derivative of C60 acting as a nanofiller and electron acceptor. The next two layers, ZnO nanoparticle layer and PEDOT:PSS polymer act as charge carrier recombination layers. The second active layer, again a BHJ nanocomposite layer is pDPP5T-2:PCBM where PCBM is the nanofiller while diketopyrrolopyrrole-quinquethiophene alternating copolymer (pDPP5T-2) is a low bandgap (1.41 eV) polymer matrix. The next ZnO layers serves as a electron transporting layer while the subsequent layer of AgNWs serves as a transparent electrode. For the reference cell, all layers have been printed by means of doctor blading except for ITO and Ag, which were sputtered and thermally deposited under vacuum, respectively [8].

The aim of this work was characterize the microstructure of the solar cell and to develop a fully printed tandem BHJ organic solar cell utilizing materials in the form of inks, among which have been AgNWs used as a top transparent electrode.

III. Main Results

A. AgNWs in Si-based Solar Cells

When two NWs are touching, they are in contact with each other through a junction, extending the percolation of the network but increasing resistance because junctions, as previously mentioned, exhibit enormous resistances of up to 1GΩ [9], several orders higher than individual AgNWs. Nanojoining of AgNW through modification of junction morphology, also called welding or joining, decreases electrical resistance i.e. enhances conductivity along with

bonding strength and fracture resistance. This leads to higher mechanical durability [10] of NW networks, a very important property for possible application in flexible optoelectronic devices.

Examples of AgNW junctions where sintering or "welding" has occurred after annealing are presented in Fig. 1 along with welded AgNW junctions with subsequent AZO deposition.

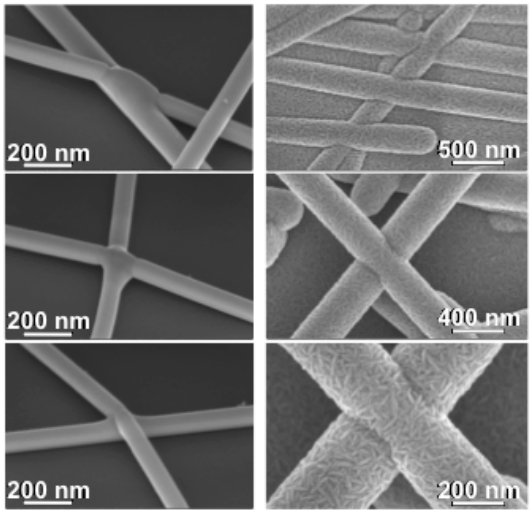

Fig. 1. SEM images of various welded AgNW junctions before (left) and after (right) AZO depositon [2].

In order to understand the morphology of this TE nanocomposite, a cross-section of the sample was made by focused ion beam (FIB) machining, a way of sample preparation for scanning transmission electron microscopy (STEM) analysis. Fig. 2 is a low magnification STEM annular dark field (ADF) image of AgNW cores encapsulated with AZO columnar nano-grain shells, displayed as white and grey regions, respectively. It is clear that the AZO film is very homogenous in thickness distribution and structure, and it seems to grow radially from the AgNWs and substrate outward. AgNWs are confirmed to have a mostly pentagonal twinned structure with fairly uniform diameter distribution [2]. Some AgNWs present in Figure 2, appear to be blurry, the result of their axes being tilted with respect to electron beam. Also shown are the electron and ion beam protective carbon deposited layers which assist against sample amorphization during FIB machining [11].

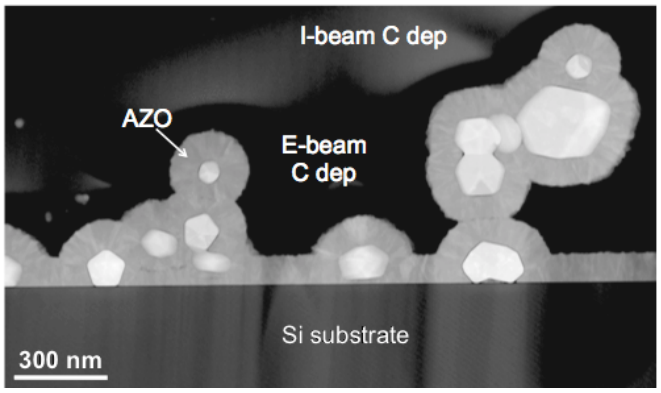

Fig. 2. ADF STEM image of AgNW/AZO cross-section [2].

HAADF STEM image of AgNW/AZO cross-section along with EDS maps noting elemental distribution of silver (turquoise), aluminum (yellow), zinc (green), oxygen (orange) are presented in Fig. 3. It can be seen that aluminum and zinc is present in the shell, while the presence of silver which is limited to the cores of the analyzed structure.

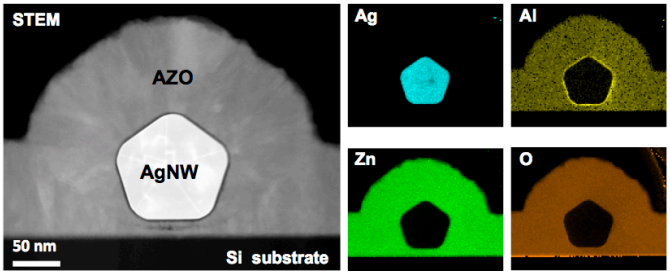

Fig. 3. HAADF STEM image of AgNW/AZO cross-section along with appropriate EDS maps noting elemental distribution of Ag, Al, Zn and O [4].

To put things in perspective of solar cells application, this nanocomposite electrode was pitted against several other electrodes including: thermally evaporated Ag grid, AZO, Ag grid/AZO, and AgNWs/AZO/Ag grid. Among all the material combinations utilized as TE in Si-based solar cell, AgNW/AZO with larger surface area of coverage (34%) exhibited the largest power conversion efficiency (PCE), as shown in Table I (noted in bold and italic), in which, besides PCE values for open circuit voltage (V_{OC}), short circuit current density (J_{SC}), fill factor (FF) and sheet resistance (R_S) are given for all electrodes [4].

TABLE I
SOLAR CELL PERFORMANCE UTILIZING VARIOUS TE [4].

Electrode	V_{OC} (mV)	J_{SC} (mA/cm^2)	FF (%)	R_S (Ω cm^2)	PCE (%)
Ag grid	553	16.3	68.4	1.8	6.1
AgNWs/AZO/ Ag grid	556	18.2	73.6	1.0	7.4
AZO/Ag grid	559	19.8	72.1	1.4	8.0
AZO	547	25.1	30.1	17.9	4.1
AgNW (16%)/AZO	559	27	31.3	23.6	4.7
AgNW (34%)/AZO	***559***	***28***	***60.1***	***4.4***	***9.4***

B. AgNWs in BHJ OSCs

For application as TE in tandem BHJ OSC, as mentioned, AgNWs have been printed from ink, by means of doctor blading. Fig. 4shows top view of the AgNW TE of our cell with an architecture (bottom to top): Glass substrate / PEDOT:PSS / Opaque Ag/ PEDOT:PSS / GEN-2 / PCBM / ZnO / PEDOT:PSS /pDPP5T-2:PCBM / ZnO / AgNW. As can be seen, the network consists of very long AgNWs,

beneficial to the percolation of electrical properties while still have enough of empty space for not hindering the optical transparency of the TE.

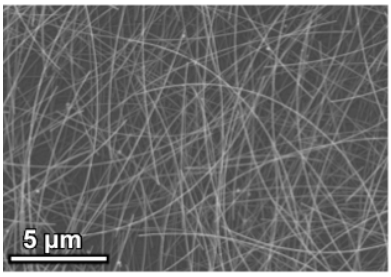

Fig. 4. SEM image of top view of cell i.e. AgNW transparent electrode [2].

Fig. 5 (left) represents the schematic of the solar cell while Fig. 5 (right) is a bright field conventional transmission electron micrograph (CTEM) obtained by lifting out a thin lamella from sample by means of FIB, just like in the previous section regarding the AgNW/AZO nanocomposite. The same architecture, but with polyethylene terephthalate (PET) polymer as a flexible substrate, was not possible to characterize by means of TEM as it was not possible to acquire a lamella by FIB. From the CTEM image it can be seen that fairly uniform thicknesses can be observed for all layers except the AgNWs, suggesting that charge carrier diffusion to their respective electrodes should be uniform throughout the cell. In the case of AgNWs, non-homogenous thickness as well as high surface roughness is expected as AgNWs are essentially a network, not a continuous film.

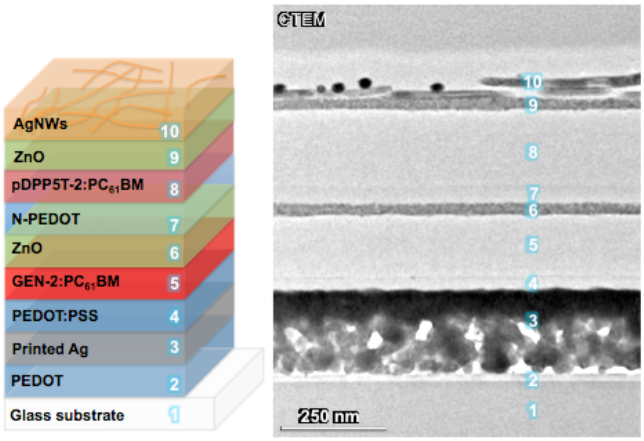

Fig. 5. Left: Schematic of tandem BHJ OSC architecture with layers numbered "1-10" in order of deposition (bottom to top); Right: CTEM image cell cross-section, numbers "1-10" note layers which correspond to image on the left [8].

Concerning AgNWs, a polymer capping agent PVP, introduced during synthesis in order to stabilize AgNWs [8], prevents direct contact of AgNWs and ZnO nanoparticles, which increases resistance and contributes to lower FF and PCE. This capping agent, noted as an amorphous region in Fig. 6, although negatively impacting the PCE (by increasing electrical sheet resistance), is detrimental to the formation and growth of AgNWs during synthesis. It can cleary be seen that the cross sections of the AgNWs are of pentagonal shape, due to them having five tetrahedral five twinned sub-segments inherent from the synthesis process [12], as well as the uniform thickness of the ZnO layer, as previously mentioned.

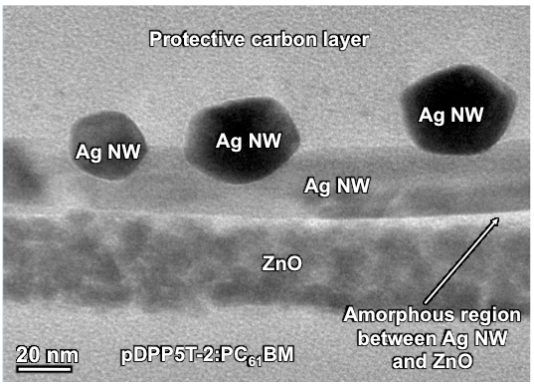

Fig. 6. HAADF STEM image of AgNW/AZO cross-section along with appropriate EDS maps noting elemental distribution of Ag, Al, Zn and O [2].

Exceptional properties of AgNWs such as high optical transparency and low sheet resistance (as well as high reflectance and low sheet resistance of the, also printed opaque Ag reflective electrode) ensured sufficient light absorption in the active layers and efficient charge carriers collection. With the incorporation into a fully printed tandem OSC where interface engineering and optimization of layer compatibility was performed, the resulting cells without the use of ITO and vacuum-deposition steps achieved high PCEs of 5.81% and 4.85% on glass and flexible PET substrate, respectively [8].

TABLE II
SOLAR CELL PERFORMANCE UTILIZING VARIOUS ELECTRODES [8].

SC Architecture	V_{OC} (V)	J_{SC} (mA/cm^2)	FF (%)	PCE (%)
Glass / ITO / GEN-2 / pDPP5T-2 / Ag	1.29	7.61	68.4	6.48
Glass/ P_Ag / GEN-2 / pDPP5T-2 / Ag	1.29	7.38	73.6	5.81
PET / P_Ag/ GEN-2 / pDPP5T-2 / AgNWs	1.28	7.02	72.1	4.85

IV. CONCLUSIONS

Novel materials or novel applications for existing materials have to be constantly invented as the needs of industries like the optoelectronic industry are ever-growing. Flexible, low cost materials as well as cost effective methods of synthesis and processing are something that is highly desired. In our work we have utilized AgNW based transparent electrodes in two different kinds of solar cells. In the case of first generation Si-based solar cells, the AgNW/AZO

nanocomposite has outperformed several materials. In the case of third generation tandem BHJ OSC, the results show that the solar cell architecture with AgNWs as the top TE exhibits a power conversion efficiency comparable to similar architecture using materials whose processing methods are very demanding and expensive. It has also been shown that the flexible version of the BHJ OSC with AgNW as the TE has also a very comparable power conversion efficiency, exhibiting its potential in flexible optoelectronics.

***Sadržaj* — U ovom radu izvršena je komparativna analiza električnih karakteristika i napona praga p-kanalnih VDMOS tranzistora snage, podvrgnutih NBT (negative bias temperature) naprezanju, zavisno od primene različitih mernih procedura i konfigurisanih mernih uređaja. Pokazano je da iako tokom NBT naprezanja postoji odlično kvalitativno slaganje u promenama napona praga, rezultati dobijeni merenjem u proceduri pri kojoj su korišćeni uređaji u konfiguraciji sa jednom SMU (source measure unit) u izvesnoj meri odstupaju od onih sa dve SMU, a odstupanje može iznositi i do 20% nakon 168 h naprezanja.**

***Ključne reči* — VDMOS tranzistor snage; napon praga; NBT naprezanje; ozračivanje; merne procedure.**

I. Uvod

MOS komponente snage, među kojima posebno mesto zauzimaju VDMOS (*Vertical Double Diffused MOS*) tranzistori snage, zbog svojih performansi kao što su velika prekidačka brzina, visoki probojni napon, dobra termička stabilnost, visoka ulazna impedansa i mogućnost upravljanja visokim strujama, imaju veoma široku primenu. Koriste se u brojnim elektronskim uređajima i sistemima projektovanim za različite primene (u prekidačkim izvorima napajanja, u audio pojačavačima [1, 2]), u automobilskoj industriji u uređajima i sistemima koji predstavljaju i dodatnu i primarnu opremu [3]. U navedenim primenama, VDMOS tranzistori u radnom režimu trpe permanentni uticaj i jakog električnog polja i povišene temperature iz ambijenta ili kao posledica samozagrevanja. Međutim, VDMOS tranzistori snage imaju, takođe, široku primenu i u elektronskim uređajima i sistemima projektovanim za specijalne namene u radijacionom okruženju: u telekomunikacionim satelitima (kao prekidački elementi u izvorima napajanja), u vojnoj industriji, u sistemima automatike kod nuklearnih postrojenja. U ovim primenama VDMOS tranzistori snage su izloženi negativnom kompleksnom dejstvu BT (*Bias Temperature*) naprezanja i jonizujućeg zračenja, pa se od njih, osim visoke pouzdanosti, zahteva i velika otpornost na jonizujuće zračenje. [4-10]. To je osnovni razlog za višegodišnje proučavanje efekata jonizujućeg zračenja i BT naprezanja kod VDMOS tranzistora snage [11, 12]. Glavni rezultat tih proučavanja je činjenica da naprezanje tranzistora ima za posledicu nestabilnosti njihovih električnih parametara i karakteristika, u osnovi kojih su nestabilnosti gustina naelektrisanja u oksidu gejta i površinskih stanja prouzrokovanih naprezanjem. Iz tog razloga proučavanja su produbljena i usmerena na analizu formiranja i prirode naelektrisanja u oksidu gejta i površinskih stanja [13-16], u cilju praćenja i prognoze ponašanja električnih parametara ispitivanih tranzistora. Kako je za to neophodno praćenje električnih karakteristika tranzistora tokom naprezanja, imperativ je koristiti što efikasniju mernu proceduru koja podrazumeva optimalno korišćenje merne opreme. Merna oprema korišćena u ovim eksperimentima, sa hronološkog aspekta, sadržala je najpre dve SMU (*Source Measure Unit*). Međutim, iz praktičnih razloga, prešlo se na korišćenje samo jedne SMU, s obzirom da olakšava mobilnost merne konfiguracije, što je od posebnog značaja kada se merenja određenih sekvenci istog eksperimenta moraju vršiti u različitim laboratorijama, koje su međusobno fizički distancirane.

U ovom radu je izvršena komparativna analiza rezultata merenja električnih karakteristika p-kanalnih VDMOS tranzistora snage, podvrgnutih NBT naprezanju dobijenih primenom različito konfigurisanih mernih uređaja (prva konfiguracija uređaja sadržala je dve SMU dok je druga sadržala samo jednu).

II. Eksperiment

U ovim istraživanjima su kao eksperimentalni uzorci korišćeni komercijalni p-kanalni VDMOS tranzistori snage tipa IRF 9520, koji su proizvedeni u standardnoj Si-gejt tehnologiji, sa nominalnom debljinom oksida gejta od 100 nm. Tokom NBT naprezanja, pri temperaturi od 175°C, kod svih komponenata je bila primenjena polarizacija gejta od - 45 V, dok su sors i drejn bili uzemljeni. NBT naprezanje je obavljeno u Heraeus HEP2 komorama, koje su obezbeđivale stabilnu temperaturu.

U cilju praćenja degradacije komponenata NBT naprezanje je prekidano nakon prethodno definisanih vremenskih perioda

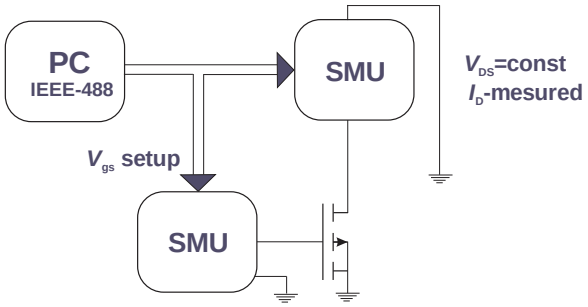
da bi se snimale prenosne karakteristike I_D-V_{GS}, na osnovu kojih je određen napon praga. Vrednosti napona praga određivane su na osnovu nadpragovskog dela prenosnih karakteristika u oblasti zasićenja, ekstrapolacijom linearnog dela $\sqrt{I_D}$–V_G krivih do preseka sa V_G-osom. Sva merenja su obavljana na sobnoj temperaturi.

Na Sl. 1 je dat šematski prikaz konfiguracije opreme za snimanje prenosnih strujno-naponskih karakteristika p-kanalnih VDMOS tranzistora snage korišćenjem dve SMU. Mernim sistemom, koji se sastojao od uređaja Keithley 237 (za polarisanje drejna i merenje struje drejna) i Keithley 2400 (za variranje-setovanje napona na gejtu u zadatim koracima), upravljano je preko personalnog računara u koji je ugradjena interfejs kartica tipa IEEE 488.



Sl. 1. Šematski prikaz konfiguracije opreme za snimanje prenosnih strujno-naponskih karakteristika p-kanalnih VDMOS tranzistora snage korišćenjem dve SMU.

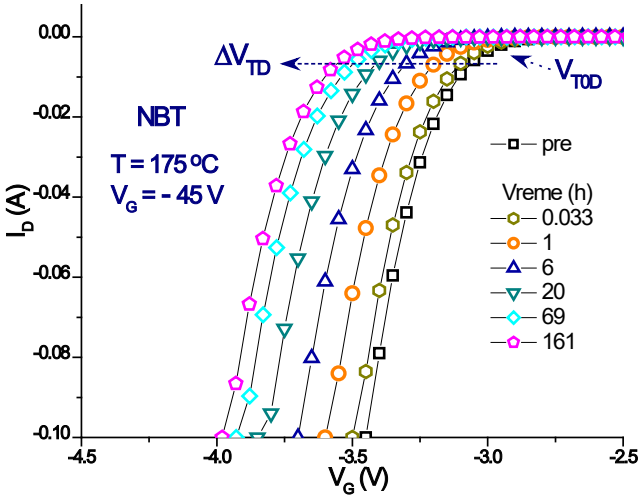
Na Sl. 2. je dat šematski prikaz i fotografija konfiguracije za snimanje prenosnih strujno-naponskih karakteristika p-kanalnih VDMOS tranzistora snage korišćenjem jedne SMU. Pri tome je korišćen visoko precizni Keysight Technologies B2901A, kontrolisan pomoću laptopa preko USB-a.

Sl. 2. Šematski prikaz i fotografija konfiguracije za snimanje prenosnih strujno-naponskih karakteristika p-kanalnih VDMOS tranzistora snage korišćenjem jedne SMU.

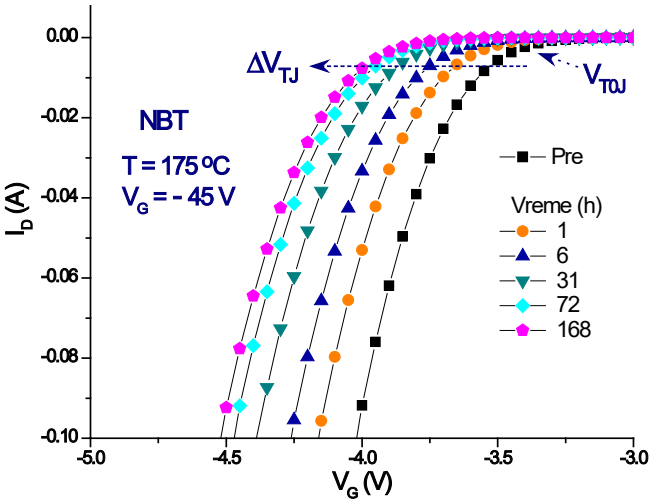
Konfiguracija prikazana na Sl. 2 (sa samo jednom SMU) je svakako jednostavnija za primenu i olakšava njenu mobilnost, što je od posebnog značaja kada se merenja moraju vršiti u različitim, međusobno udaljenim laboratorijama. To je bilo posebno značajno kada su sprovedeni uporedni eksperimenti NBT naprezanje-ozračivanje i ozračivanje-NBT naprezanje [11, 13, 14]. U ovim eksperimentima su uzorci podvrgnuti NBT naprezanju u Laboratoriji Katedre za mikroelektroniku na Elektronskom fakultetu u Nišu, a ozračivani γ-zračenjem na Co-60 izvoru u Laboratoriji za zaštitu od zračenja i zaštitu životne sredine, Instituta za nuklearne nauke “Vinča”.

III. Rezultati i diskusija

Na osnovi izvršenih merenja primenom dve i jedne SMU, promene prenosnih karakteristika p-kanalnog VDMOS tranzistora snage, tokom NBT naprezanja, prikazane su na Sl. 3 i Sl. 4, respektivno.



Sl. 3. Promene prenosnih karakteristika p-kanalnog VDMOS tranzistora snage, tokom NBT naprezanja, pri merenju konfiguracijom sa dve SMU.

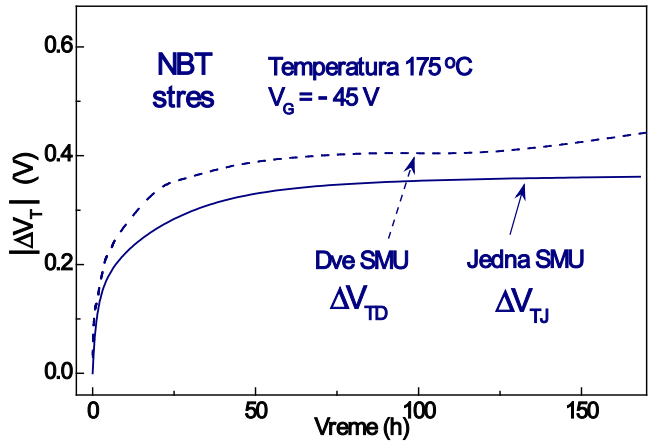


Sl. 4. Promene prenosnih karakteristika p-kanalnog VDMOS tranzistora snage, tokom NBT naprezanja, pri merenju konfiguracijom sa jednom SMU.

Na osnovu Sl. 3 i Sl. 4 se jasno uočava da tokom NBT naprezanja dolazi do pomeranja prenosnih karakteristika duž V_G ose ka negativnijim vrednostima, što ukazuje na porast napona praga ispitivanih tranzistora po apsolutnoj vrednosti. Pokazano je da do ovakvog ponašanja napona praga tokom NBT naprezanja dolazi usled porasta gustina pozitivnog naelektrisanja u oksidu gejta i na površinskim stanjima, koje su posledica odgovarajućih procesa u oksidu i na međupovršini [3, 7, 8, 13, 14, 16].

Na Sl. 5 su prikazane promene napona praga p-kanalnih VDMOS tranzistora snage određene na osnovu izlaznih karakteristika koje su merene sa dve (ΔV_{TD}) i sa jednom (ΔV_{TJ}) SMU tokom NBT naprezanja. Uočava se da su promene napona praga, dobijene merenjem u proceduri pri

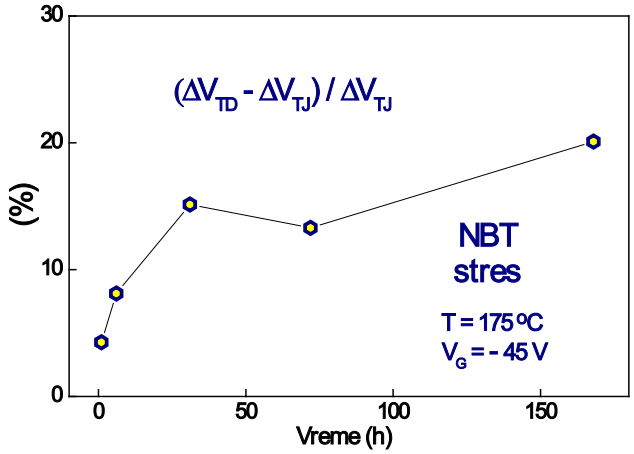
kojoj su korišćeni uređaji u konfiguraciji sa jednom SMU, manje od onih dobijenih primenom dve SMU.



Sl. 5. Promene napona praga p-kanalnih VDMOS tranzistora snage određene na osnovu izlaznih karakteristika merenih sa dve i sa jednom SMU tokom NBT naprezanja.

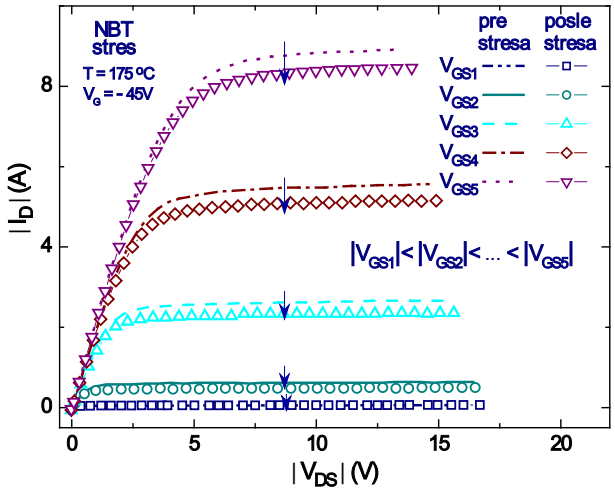
Sa Sl. 5 se primećuje da pri kraćim vremenima NBT naprezanja (do dva sata) gotovo da nema razlike u vrednostima promena napona praga, bez obzira da li se merenja vrše sa jednom ili sa dve SMU, ali da sa vremenom te razlike postaju sve izraženije do 30-ak sati, nakon čega se znatno sporije povećavaju. Na Sl. 6 su prikazane relativne promene napona praga p-kanalnih VDMOS tranzistora snage tokom NBT naprezanja, određene na osnovu izlaznih karakteristika koje su merene sa dve i sa jednom SMU. Može se videti da su te promene samo 4% nakon jednog sata NBT naprezanja, dok nakon 30-ak sati dostižu vrednost od 15% i povećavaju se do 20% nakon 168 h naprezanja.

U cilju dalje detaljnije analize uočenih razlika pri merenju karakteristika sa dve i sa jednom SMU, na Sl. 7 su prikazane izlazne karakteristike p-kanalnog VDMOS tranzistora snage pre i posle NBT stresa (naprezanja).

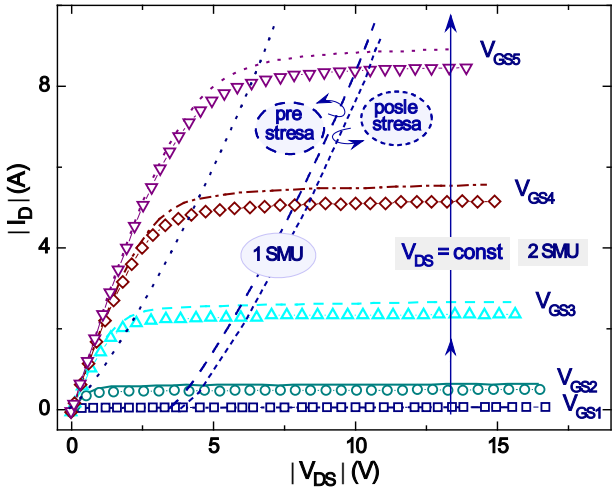


Sl. 6. Relativno odstupanje dobijenih promena napona praga p-kanalnih VDMOS tranzistora snage, pri merenju prenosnih I-V karakteristika sa dve i sa jednom SMU tokom NBT naprezanja.

Na Sl. 7a se može uočiti tendencija promena izlaznih karakteristika nakon NBT stresa, odnosno njihovo potiskivanje ka manjim (apsolutnim) vrednostima struja drejna, usled porasta napona praga, a sa Sl. 7b razlike pri merenju prenosnih karakteristika sa dve i sa jednom SMU.



(a)



(b)

Sl. 7. Izlazne karakteristike p-kanalnog VDMOS tranzistora snage pre i posle NBT stresa na kojima se zapaža: (a) tendencija pomeranja karakteristika i (b) razlike pri merenju prenosnih karakteristika sa dve i sa jednom SMU.

Pri merenju sa dve SMU napon na drejnu V_{DS} je konstantan (tipično 5 V ili više), napon koji se dovodi na gejt (V_{GS}) menja se u zadatim koracima, a meri se struja drejna (I_D). Pri tome, tranzistor je duboko u zasićenju, a merene tačke leže na vertikalnoj pravoj. Kao što je pomenuto, jednom SMU je variran napon na gejtu, dok je drugom vršeno polarisanje drejna i merenje struje drejna. U slučaju merenja sa jednom SMU drejn i gejt su kratkospojeni, tranzistor je konstantno u zasićenju, ali napon na drejnu klizi tokom merenja. Kako je parabola koja razdvaja triodnu od oblasti zasićenja definisana naponom $V_{DSsat}=V_{GS}-V_T$, to se merenjem sa kratkospojenim gejtom i drejnom ($V_{GS}=V_{DS}$) krećemo po paraboli koja je za vrednost V_T potisnuta u oblast zasićenja. Pored toga, sa povećanjem napona na drejnu smanjuje se efektivna dužina kanala (modulacija dužine kanala), te karakteristike u oblasti zasićenja nisu idealno paralelne naponskoj osi (V_{DS}), što je posebno izraženo kod p-kanalnih tranzistora. Sa Sl. 7 se može

primetiti da su razlike između karakteristika pre i posle stresa veće pri većim vrednostima V_{DS}, kada je tranzistor dublje u zasićenju. Kako se merenja karakteristika primenom dve SMU vrše kada je tranzistor duboko u zasićenju jasno je da će i dobijene vrednosti za promenu napona praga biti veće. Pri istoj vrednosti V_{GS} procedura sa dve SMU daće veću struju I_D, što prividno odgovara manjoj vrednosti napona praga, ali i njegovoj većoj promeni. Značajno odstupanje rezultata sa Sl. 3 i Sl. 4 posledica je ovog efekta, ali i same činjenice da su početne vrednosti napona praga bile različite, pri čemu su u slučaju dve SMU (Sl. 3) bile $V_{T0D} = 3$ V, a u slučaju jedne SMU (Sl. 4) $V_{T0J} = 3.4$ V.

IV. Zaključak

Nestabilnosti električnih parametara MOS tranzistora pri NBT naprezanju direktna su posledica nestabilnosti gustina naelektrisanja u oksidu gejta i površinskih stanja. U cilju rasvetljavanja odgovornih elektrofizičkih mehanizama, istraživanja su usmerena na analizu električnih parametara, pri čemu je za praćenje električnih karakteristika tranzistora tokom naprezanja neophodno koristiti što efikasniju mernu proceduru koja podrazumeva i optimalno korišćenje merne opreme. U ovom radu je izvršena komparativna analiza rezultata merenja električnih karakteristika p-kanalnih VDMOS tranzistora snage, podvrgnutih NBT naprezanju, dobijenih primenom različito konfigurisanih mernih uređaja - prva konfiguracija uređaja sadržala je dve SMU, dok je druga sadržala samo jednu SMU.

Pokazano je da iako postoji odlično kvalitativno slaganje u promenama napona praga tokom NBT naprezanja, rezultati dobijeni merenjem u proceduri pri kojoj su korišćeni uređaji u konfiguraciji sa jednom SMU u izvesnoj meri odstupaju od onih sa dve SMU, a odstupanje može iznositi i do 20% nakon 168 h naprezanja. Dobro kvalitativno slaganje i neznatno odstupanje ukazuje da se rezultati dobijeni u prethodnim, kao i u izmenjenim (unapređenim) mernim procedurama mogu u određenoj meri koristiti i u drugim eksperimentima različitih naprezanja p-kanalnih VDMOS tranzistora snage, a u cilju dobijanja pouzdanih podataka neophodnih za prognozu ponašanja njihovih električnih parametara.

Zahvalnica

Prikazani rezultati dobijeni su u okviru istraživanja na projektima OI171026 i TR32026 koje finansira Ministarstvo prosvete, nauke i tehnološkog razvoja Republike Srbije i na projektu "Osobine tankih i ultratankih oksidnih slojeva" (F-148), koji finansira Srpska akademija nauka i umetnosti-SANU.

Abstract

In this paper comparative analyzis of electrical characteristics and threshold voltage shift of NBT (negative bias temperature) stressed p-channel power VDMOS transistors, depending on applied measuring procedures, was performed. It was shown that although there is good qualitative behaviour of threshold voltage shift obtained by measuring configuration by one and by two SMU, relative deviation of threshold voltage shift might be almost 20% after 168 h of NBT stress.

Electrical characteristics measurement procedures of stressed p-channel power VDMOS transistors

Wideband Antenna Array for mm-Wave Radar Modules Characterization

Siniša Jovanović, *Member, IEEE*, Ivan Milosavljević, *Member, IEEE,* Veselin Branković

***Abstract*—This paper outlines the design and realization of one type of antenna array developed for testing of integrated FMCW transmitter modules operating in the unlicensed 60-GHz band.**

All important features such as the type and design of the radiating elements of the array, the configuration of the biasing network as well as the substrate stack-up are adjusted for achieving a very wide operational frequency range, with almost constant antenna gain, from 50 to 70 GHz. To accommodate various test scenarios, four antenna versions are fabricated with low or high gain and with a coaxial connector or waveguide input port.

The fabricated antennas are employed in various test setups for characterization of two versions of millimeter-wave FMCW chips realized in 0.13-µm SiGe BiCMOS technology: a transmitter module operating from 59.5 GHz to 70.5 GHz and a complete radar transceiver module operating from 54 GHz to 65 GHz.

***Index Terms*—Antenna array, millimeter-wave frequency range, FMCW radar module.**

I. Introduction

An unlicensed industrial, scientific and medical (ISM) band ranging from 57 to 64 GHz has recently been gaining increased attention due to its potential to meet the demand of high data-rate wireless communications as well as short-range radar and secure communication within a limited area [1]. All potential applications in this frequency range benefit from a high path loss caused by atmospheric oxygen absorption which allows massive usage of such devices in relative proximity without unwanted interference.

Significant potential for implementation in various fields of everyday human occupations belongs to miniature short-range contactless microwave radar systems due to their capability to operate in bad weather conditions and in harsh environments. The potential fields of application for these radar systems are healthcare, the automotive industry, surveillance, infrastructure maintenance, agriculture and many more areas yet to be acknowledged [2]–[4].

For wider and cost-effective commercial applications, mm-wave radar sensors should be single-chip integrated devices with a low unit cost and small physical size. Over the past few years, Novelic Microsystems developed and realized two modules for application in this frequency range: a SiGe highly integrated FMCW transmitter module that can generate 11 GHz frequency ramps (from 59.5 to 70.5 GHz) with a single continuous sweep [5]; and a fully integrated FMCW radar sensor containing both a transmitter and receiver chain and operating from 55 to 64 GHz [6]. For providing the required working environment as well as for the testing and characterization of these devices, several specific RF and microwave components were developed and integrated within various RF boards [7]. All RF components were required to cover a wider frequency range than the expected operational limits of the FMCW units in order to compensate for the fabrication tolerances as well as the uncertainty induced by the innovative antenna topology.

Various types of antenna arrays were designed and realized to support the development of these FMCW modules. Some antennas were integrated within RF boards and connected to Tx and Rx ports of the FMCW chips. Other antennas were required within the test setups during the testing and characterization of the FMCW modules with an operational frequency range even wider than the expected range of the modules. This paper describes the design and realization of these supporting antennas that were indispensable for the complete characterization of the newly developed FMCW radar modules.

II. Antenna Design

To provide the applicability in all possible testing scenarios and fabrication tolerances during the fabrication of integrated radar modules, the test antennas should cover a very broad frequency range - as wide as from 50 GHz up to 70 GHz. Since a bandwidth of classic microstrip patch antennas is up to 5%, typically, they were unsuitable for usage as the array's radiating elements. However, the required frequency bandwidth can be achieved by an antenna array consisting of customized bowtie-shaped dipoles illustrated in Fig. 1. The basic radiation element of all arrays presented in this paper is a two-sided printed dipole placed on the top and the bottom layer of a thin dielectric substrate with a reflecting plane placed at $\approx\lambda_0/4$ behind the antenna plane, with air between the reflector and the antenna. The dipole can be defined with a small set of parametrized dimensions and modeled in various program packages for EM analysis and simulation [8,9]. By fine-tuning the dipole's parameters, its input impedance can be adjusted to match approximately 100 Ω over a broad frequency range similar to pentagonal-shaped dipoles described in [10].

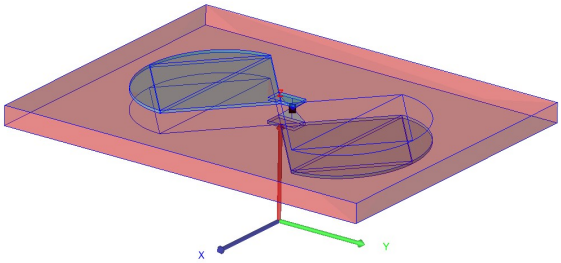

Fig. 1. 3D model in WIPL-D [8] of two-sided printed dipole which is a basic radiating element of antenna array

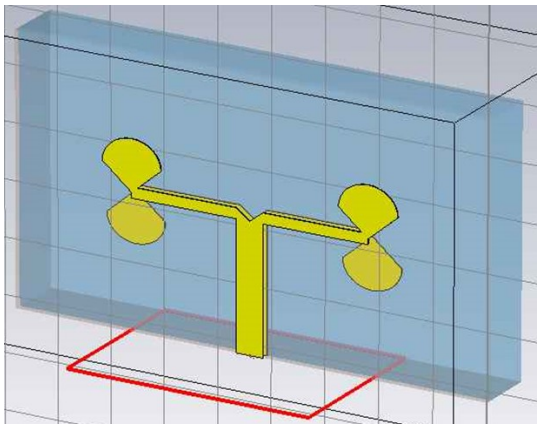

Fig. 2. 3D model of 2×1 antenna array.

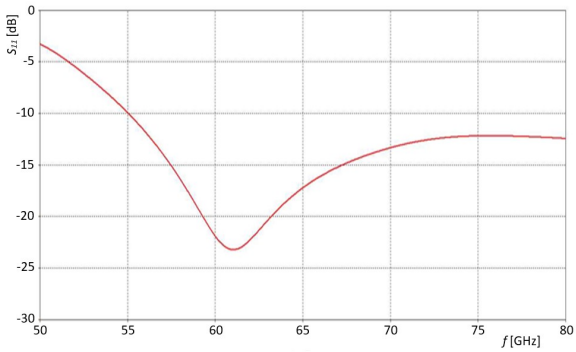

Fig. 3. Return Loss frequency characteristics of 2×1 antenna array obtained from 3D EM simulation.

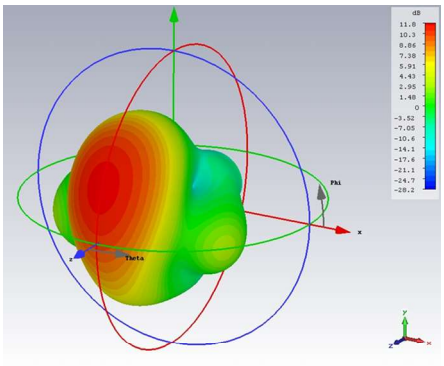

Fig. 4. 3D Radiation diagram of 2×1 antenna array obtained from 3D EM simulation.

Each dipole is fed by a symmetrical microstrip transmission line with a characteristic impedance of 100 Ω. Pairs of adjacent dipoles with associated feeding lines are connected over a simple T-junction forming a dipole pair with 50 Ω input impedance as shown in Fig. 2. In that manner, good matching can be achieved in a very wide frequency range as presented in Fig. 3 that shows an *RL* better than 10 dB in a frequency range from 55 GHz to above 80 GHz.

Fig. 4 shows the 3D radiation diagram of the 2×1 antenna array. It has a very wide 3 dB radiation beam of 60° in E plane (yz) and 35° in H plane (xz) with a maximum gain of 11.8 dBi which is steered by about 20° in E plane due to the influence and coupling with the main feeding line. For higher order arrays, having a bigger number of radiation elements, this influence is less pronounced because the feeding network and antenna array structure is more symmetrical.

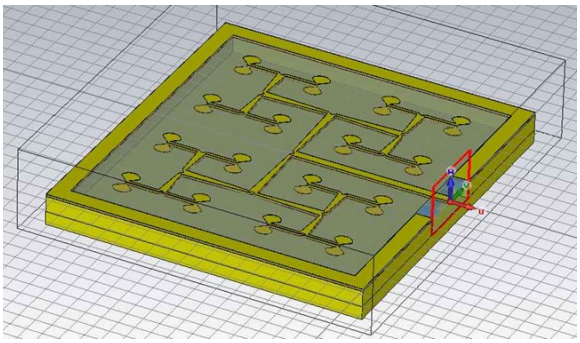

Fig. 5. 3D model of 4×4 antenna array

Fig. 5 shows a 3D model of the 4×4 antenna array. The distances between the radiating elements are $d_v = 4.4$ mm along v axis, and $d_u = 4.8$ mm along u axis. The model contains a metalized frame around the array for mechanical support of the array and preventing its bending. The frame is included into the 3D model to ensure that it will not have a negative influence on the overall characteristics.

Besides the main feeding line of $Z_c = 50\ \Omega$ and dipole feeding line of $Z_c = 100\ \Omega$, the feeding network contains a system of tapered 50 Ω to 100 Ω transformers. In that manner, good matching is achieved in a wide frequency range as shown in Fig. 6 with *RL* better than 10 dB from 54 GHz to above 80 GHz.

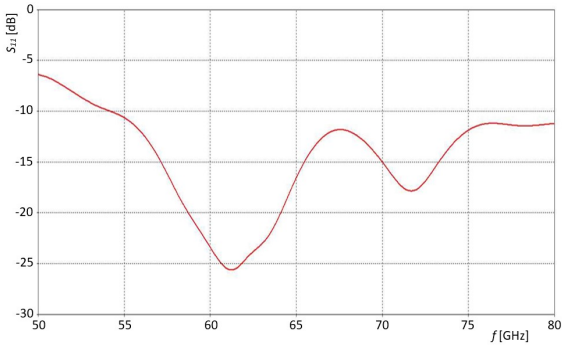

Fig. 6. Return Loss frequency characteristics of 4×4 antenna array obtained from 3D EM simulation.

Fig. 7 presents a 3D radiation diagram of the 4×4 antenna array showing a maximum gain of 20.8 dBi.

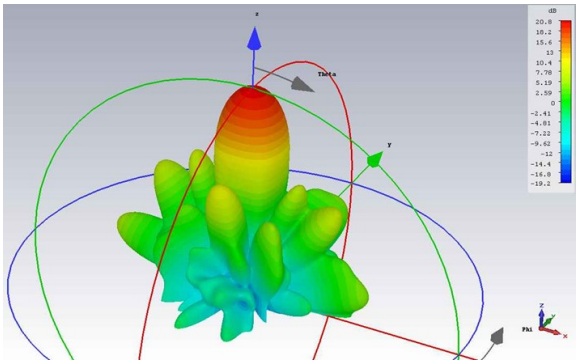

Fig. 7. 3D Radiation diagram of 4×4 antenna array obtained from 3D EM simulation.

Fig.8 presents the maximum gain of the 4×4 array from 50 to 80 GHz showing that the antenna array has a very wide usable frequency range with a gain better than 20 dBi from 57 to 72 GHz and a gain better than 18 dBi within the whole observed range.

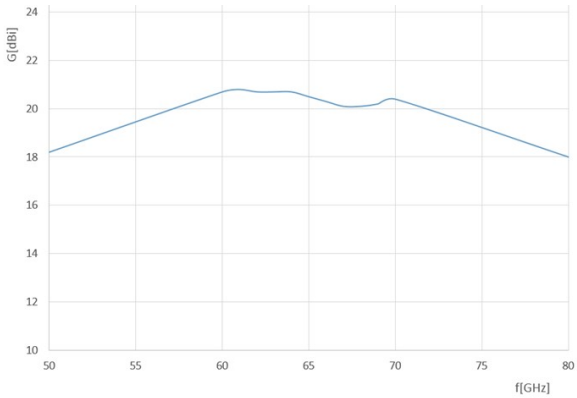

Fig. 8. Maximum Gain of 4×4 array vs. frequency obtained from 3D EM simulation.

All presented 3D models contain a multi pin waveguide port that provides the ideal balanced antiphase excitation for the analyzed arrays. For practical realization, it is necessary to provide a transition from such a balanced port to more practical ports such as either coaxial or waveguide. Fig. 9 shows a 3D model of CPWG to symmetrical microstrip (SMS) transition which consists of five sections. At the right end of the structure shown in Fig. 9, it is a CPWG transmission line with a central conductor surrounded with reference ground both at the bottom layer of the dielectric and at the top layer. The length of this section must be sufficient to match mechanical dimensions for the selected connector type. The next section is a transition from CPWG transmission line to standard unbalanced microstrip transmission line, followed by a very short unbalanced microstrip line. The next section is unbalanced to balanced microstrip line transition and finally a section of balanced microstrip line which belongs to an antenna array feeding network.

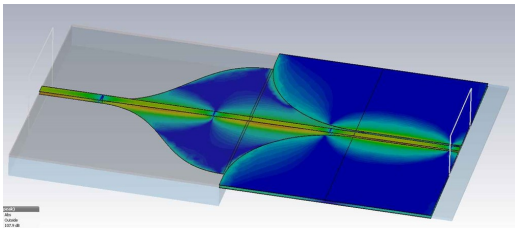

Fig. 9. E-field distribution at a transition from CPWG to symmetrical microstrip transmission line .

Fig. 10 shows the partial cross section of a 3D model of a symmetrical microstrip to WR-15 waveguide transition. The transition can be optimized by changing the length and the curvature of the fences. Both transitions were optimized to provide minimum insertion loss, less than 0.2 dB within the whole frequency range of interest.

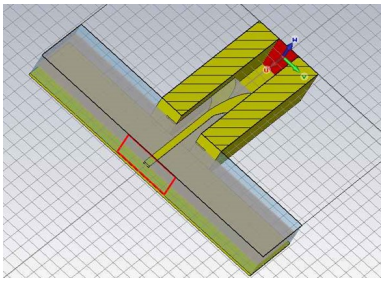

Fig. 10. 3D model of a transition from WR-15 type waveguide port to symmetrical microstrip transmission line (partial cross-section).

III. Realization

Based on the analysis performed in the previous section, four versions of antenna arrays are designed for fabrication of experimental models: 4×4 and 2×1 antenna arrays combined with both SMS to WG and SMS to coaxial connector transitions.

All printed antennas are fabricated on a teflon-fiberglass substrate having $\varepsilon_r = 2.17$, $\tan\delta = 0.0009$ and $h = 0.127$ mm. A standard photolithography process is used with tolerances better than ±10 μm. Fig. 11 shows a photo of all four versions of the antenna arrays with brown copper metallization of the top layer and black shadow of the bottom metallization.

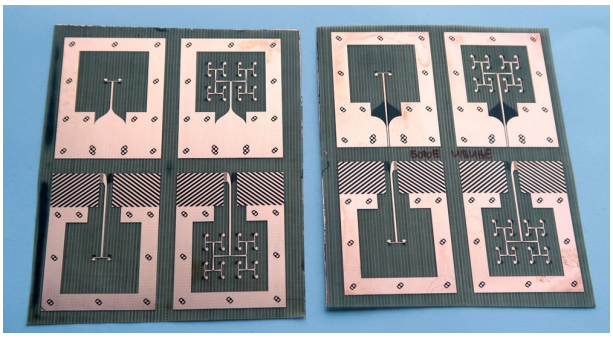

Fig. 11. Photo of two manufactured sets of printed antenna arrays: bottom side (left) and top side (right).

Fig. 12 shows a partially and a fully assembled 4×4 antenna array with WR-15 flange, while Fig. 13 shows assembled 4×4 and 2×1 antenna arrays with 2.4 mm SMA connectors.

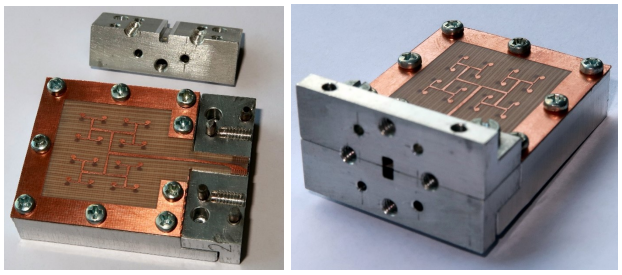

Fig. 12. Partially assembled (left) and assembled (right) 4×4 antenna array with WR 15 waveguide

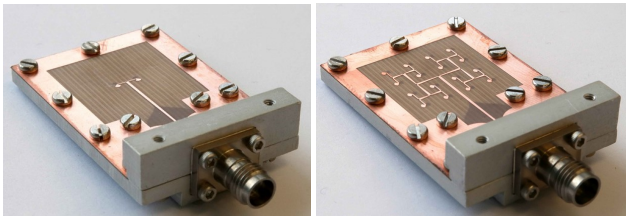

Fig. 12. Assembled antenna arrays with 2.4 mm connector

IV. Measurements

Fig. 13 shows Vector Network Analyzer ANRITSU MS4647A that is used for experimental verification of all realized antennas. The VNA, having a frequency range up to 70 GHz is used for Return Loss measurement as well as free space loss measurement. The free space loss data is post-processed for obtaining the maximum gain of the measured antennas.

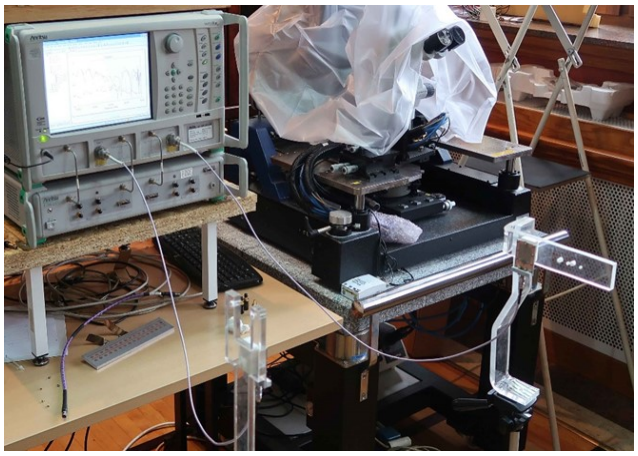

Fig. 13. Setup for free space loss measurement of two identical antennas

Fig. 14 shows measured results for the 2×1 antenna array with a 2.4 mm connector. The S_{11} and S_{22} are the return losses at the transmitting and the receiving antenna, respectively. A matching better than -10 dB is achieved in the wide frequency range starting from 53 GHz. The *RL* results include the influence of the 2.4 mm connector. The G trace shows the antenna gain reduced for the influence of the insertion loss of the connector, while Gc shows the corrected antenna gain.

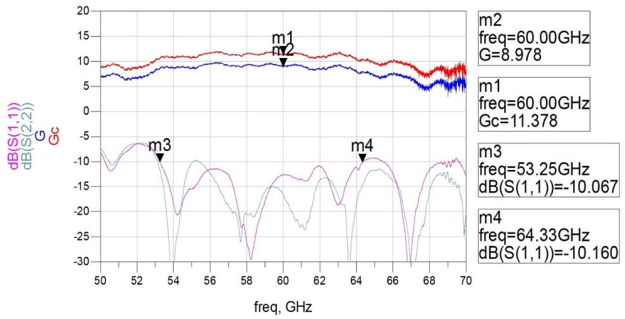

Fig. 14. Measured results for the gain of 2×1 antenna array: G (blue line) – gain with connector losses; Gc (red line) – gain excluding connector losses

Fig. 15 shows measured results for the 4×4 antenna array with the 2.4 mm connector. The S_{11} and S_{22} are the return losses at the transmitting and the receiving antenna, respectively. A matching better than -10 dB is achieved in a wide frequency range starting from 54.3 GHz. The *RL* results include the influence of the 2.4 mm connector. The G trace shows the maximum antenna gain of 17.9 dBi at 60 GHz, which is reduced due to the influence of the insertion loss of the connector. Gc shows the corrected antenna gain with a maximum value of 20.1 dBi at 60 GHz. A high antenna gain above 18 dBi is achieved in a very wide frequency range from 54 GHz to 66 GHz. The measurements of the antenna arrays with waveguide connectors show the same results for the maximum antenna gains.

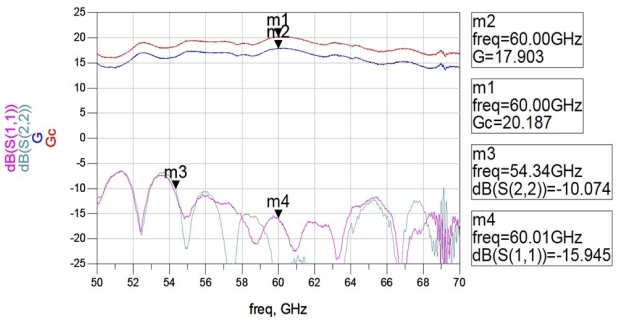

Fig. 15. Measured results for the gain of 4×4 antenna array: G (blue line) – gain with connector losses; Gc (red line) – gain excluding connector losses

V. Conclusion

The paper presents design realization and measuring results for a set of wideband antenna arrays operating at a mm-wave frequency range. The obtained characteristics of all versions of the realized antennas are in good accordance with the results obtained by 3D EM analysis. The antennas were employed within various test setups for the characterization of FMCW integrated radar modules described in papers [5,6].

ACKNOWLEDGMENT

The results shown in this paper are the outcome of a development project funded by Novelic Microsystems.

This paper was partially supported by the Ministry of Education, Science and Technological Development of the Republic of Serbia under grant TR-32024.

Comparison of the Measured Characteristics of Schottky Diodes for Power Harvesting Applications

Branka Milosevic, Milos Radovanovic, Branka Jokanovic, *Senior Member, IEEE*

***Abstract*—This paper presents a new procedure for wide-band measurement of the Schottky diode impedance and rectified DC voltage. Two different Si Shottky diodes are measured, zero-bias SMS 7630 and low barrier MP 2005. Measurement is performed with Vector Network Analyzer (VNA) in the frequency range 0.5 - 5 GHz. The RF input power is varied from -28 to 2 dBm and several different values of load resistance are used. Since measurement required definite power levels at the diode ports, both S-parameter calibration and nonlinear power calibration of VNA were applied. Complex impedance and power conversion efficiency (PCE) of two diodes were compared. It was concluded that SMS 7630 is more sensitive in the almost whole power range. Also, it was noted that both diodes have similar complex impedance which means they can be used with the same antenna, that is designed to have an input impedance complexly conjugate in relation to the rectifying diode.**

***Index Terms*—Complex impedance measurement, power conversion efficiency, zero-bias Schottky diode, low barrier Shottky diode.**

I. Introduction

The main motivation for measuring the complex impedance and power conversion efficiency (PCE) of the Shottky diodes is their use for RF energy harvesting applications. RF energy harvesting is a process in which ambient electromagnetic radiation is collected, rectified, and then stored or used for powering low-power devices. Knowing that ambient electromagnetic radiation posseses very low power density, it is necessary to have rectification element that is able to work on lower input powers and at the frequencies assigned for wireless transmission. The basic elements of RF Energy Harvesting system are antenna, rectifier and power management circuitry. Combination of antenna, impedance matching circuit and rectifier, is often referred in literature with the common name rectenna [1]. One of the final goals of the diode measurement is to get data necessary for the design of rectenna with good performances, but without impedance matching circuit, because it brings additional losses to already low-level collected power. For that reason, it was useful to measure complex impedance of the rectifying diode, in order be able to design an antenna that would have acceptably matching impedance on the frequencies of interest.

In order to increase DC power collected from RF energy harvesting, multiple rectenna elements are used. Two approaches can be considered while designing a rectenna array. Block diagrams of both approaches are shown on Fig. 1. Rectenna array in Fig. 1. (a) combines collected RF power from antennas into a single rectifier. In rectenna array shown in Fig. 1. (b) output power of every antenna element is first rectified, and then combined later. According to results presented in [2], first approach leads to more harvested DC power near the main beam, while second topology results in more harvested power at angles away from broadside. Knowing power conversion efficiency of rectifying element can help when deciding which of these two topologies to use.

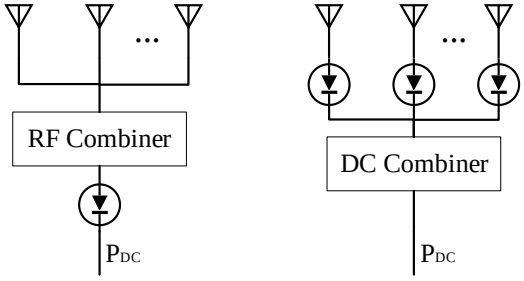

Figure 1. Two types of rectenna array: (a) with RF combiner and only one rectifying element, and (b) with rectifying element on every antenna and DC combiner

In this paper, two different Schottky diodes are measured, and results of the measurements are compared. Schottky diodes are chosen as the most frequently used diodes in RF energy harvesting application. Measured diodes are *flip-chip* Si Schottky diodes: SMS 7630 (zero-bias) and MP 2005 (low barrier). Parameters of these diodes, according to their data sheets [3, 4], are shown in Table 1.

TABLE I
PARAMETERS OF THE SHOTTKY DIODES

Parameter	**SMS 7630**	**MP 2005**
Breakdown voltage V_B	2 V (I_R=100 µA)	1 V (I_R=10 µA)
Forward voltage (max) V_F	240 mV (I_f=1 mA)	290 mV (I_f=1 mA)
Total capacitance C_T	0.2 pF (f=1 MHz)	0.18 pF (f=1 MHz)
Series resistance R_S	20 Ω	16 Ω

II. Measurement and Results

For measurement of the diode's impedance, VNA was used that also served as RF source with frequency and power sweep. The output DC voltage of the diode, which was used to calculate PCE was measured by oscilloscope. Power calibration that provides accurate power levels for both impedance and PCE measurements was done by power meter.

Block diagram for both calibration and measurement is shown in Fig. 2. Three different pairs of reference planes can be identified at: AA', BB' and CC'. At reference planes AA', Vector Network Analyzer (VNA) can be considered calibrated, but measurements are supposed to be performed at reference planes CC'. For that reason, it is necessary to calibrate VNA, and complete calibration procedure will be explained in following subsection.

A. Calibration procedures

For the S-parameter calibration at the reference planes BB', full two-port SOLT (short-open-load-thru) calibration is performed. Coaxial standards needed for this calibration are provided in calibration kit.

In order to calibrate reference plane CC', custom LRL (line-reflect-line) calibration set was designed (see Fig. 3). The LRL is a calibration algorithm that uses two or more transmission lines and a reflect standard for each port. Difference in the transmission line lengths ΔL is important parameter for the LRL calibration, since it will not work if ΔL equals to integer multiplicity of the half wavelength. Theoretically, the electrical length of ΔL should be between 0 and 180 degrees for all frequencies. Due to line parasitics, spurious modes and other problems, it is recommended to keep ΔL between 20 and 160 degrees [5].

The reflect standard for LRL calibration can be open or short circuit, and it is only important that it's symmetric with not too high return loss. In this case, short circuit was used. All standards used for this calibration are displayed in Fig. 2. Standards are designed as 50 Ω-coplanar waveguide (CPW) transmission lines on the substrate RO 3010 (ε_r=11.2, h=0.635 mm, t=0.017 mm) since the device under test (DUT) also contains 50 Ω-CPW lines with series mounted flip-chip diode. CPW technology was chosen due to simple diode assemblies and almost constant line characteristics in a wide frequency range (low dispersion).

Measurement of PCE requires accurate power levels at reference plane CC'. For that reason the source power calibration was performed with external HP 438A Power Meter and HP 8481 power sensor. It wasn't possible to use power sensor at the reference planes CC', so the power calibration was performed at the reference planes BB'. The difference in power levels between reference planes BB' and CC' was recalculated later.

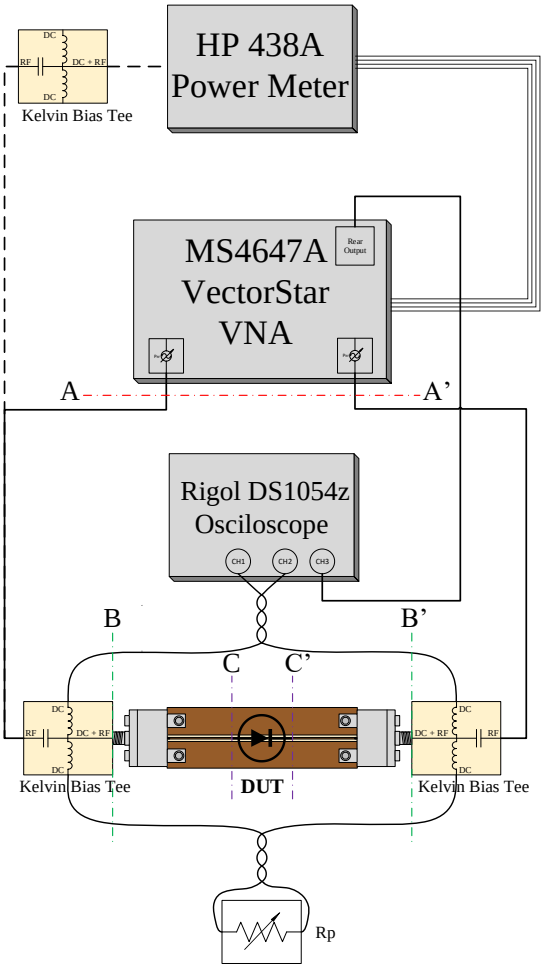

Fig. 2. Block diagram of the measurement set-up. DUT is placed between C-C' reference planes.

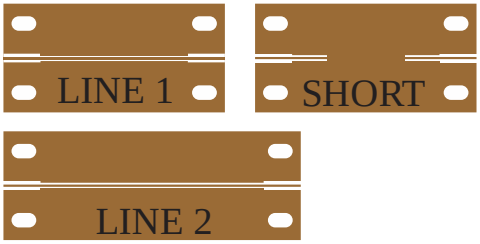

Fig. 3. Standards for the LRL calibration with CPW transmission lines: LINE1=20.2 mm, LINE2=30.6 mm, double SHORT circuit.

B. Results and comparison

Results of interest in our case were complex impedance and PCE of the two diodes. In order to calculate complex impedance from measured S parameters equivalent π-network was used, with diode's impedance in the middle and port's impedance on sides. According to [6], value of that impedance is:

$$Z_D = -\frac{1}{Y_{21}(S_{21}, S_{11})}, \tag{1}$$

where Y_{21} is obtained from following expression:

$$Y_{21} = \frac{-2S_{21}}{(1+S_{11})^2 - S_{21}^2} \cdot \frac{1}{Z_0}. \tag{2}$$

PCE was calculated from measured voltage as:

$$\eta = \frac{\frac{V_{OSC}^{\ 2}}{R_{LOAD}}}{P_{IN}}. \qquad (3)$$

In Fig. 4.-6. complex impedance of both diodes is shown. It can be noted that measured values of impedance are similar for input powers greater than -8 dBm, which is especially visible on Fig. 5. On Fig. 4., values for impedance are vastly different, because MP 2005 diode wouldn't work for low input power P_{IN} = -18 dBm.

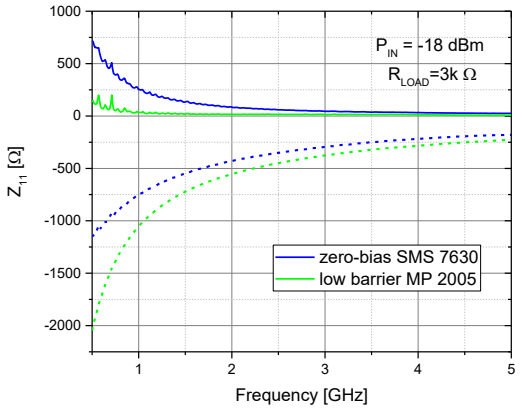

Fig. 4. Complex impedance of SMS 7630 and MP 2005 diodes for input power P_{IN} = -18 dBm and R_{LOAD} = 3 kΩ. Real part of the impedance is presented with solid, while imaginary part is presented with dashed line.

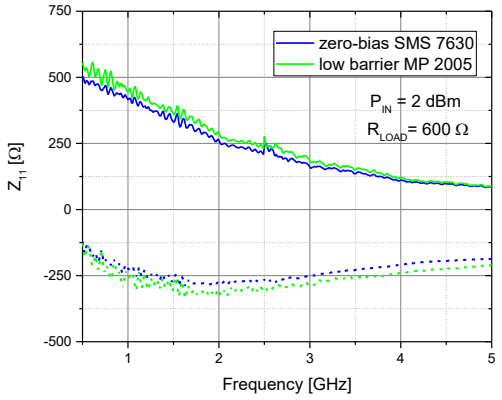

Fig. 5. Complex impedance of SMS 7630 and MP 2005 diodes for the input power P_{IN} = 2 dBm and R_{LOAD} = 600 Ω. Real part of impedance is presented with solid, while imaginary part is presented with dashed line.

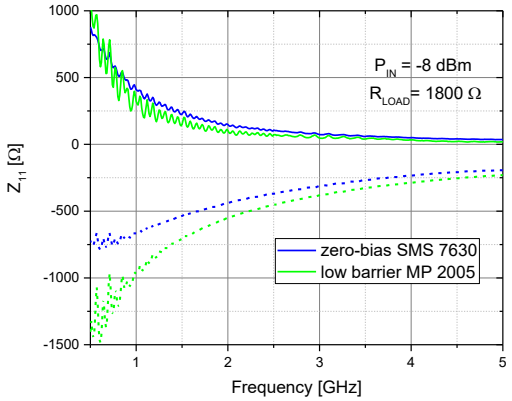

Fig. 6. Complex impedance of SMS 7630 and MP 2005 diodes for the input power P_{IN} = -8 dBm and R_{LOAD} = 1.8 kΩ. Real part of impedance is presented with solid, while imaginary part is presented with dashed line.

Complex impedance of both diodes, as function of input power, is shown in Fig. 7.-8. It can be noted that MP 2005 has significantly lower resistance for input power smaller than -8 dBm, probably because it barely works at power levels lower than that.

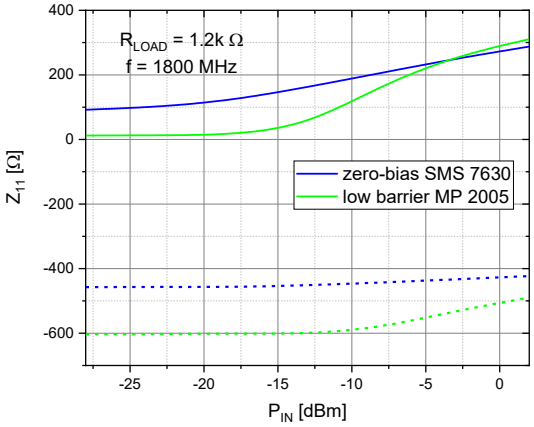

Fig. 7. Complex impedance of SMS 7630 and MP 2005 diodes as function of input power P_{IN}, on frequency f = 1800 MHz and load impedance R_{LOAD} = 1.8 kΩ. Real part of impedance is presented with solid, while imaginary part is presented with dashed line.

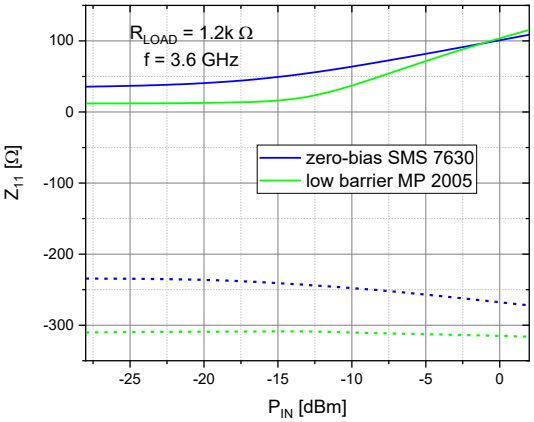

Fig. 8. Complex impedance of SMS 7630 and MP 2005 diodes as function of input power P_{IN}, on frequency f = 3.6 GHz and load impedance R_{LOAD} = 1.8 kΩ. Real part of impedance is presented with solid, while imaginary part is presented with dashed line.

Comparison of PCE of two diodes is shown in Fig. 9.-10. It can be seen that the diode SMS 7630 always perform better for lower input power, which was expected. However, MP 2005 diode becomes more efficient for the input powers larger than 1 dBm, at working frequency f = 900 MHz (Fig. 9.). If working frequency is f = 2.4 GHz, then SMS 7630 diode would be more efficient for all values of the input power that is used in this measurement (Fig. 10.). If we could choose between two topologies shown in Fig. 1., first approach probably would be preferable for SMS 7630 diode, but MP 2005 would work significantly better with second topology.

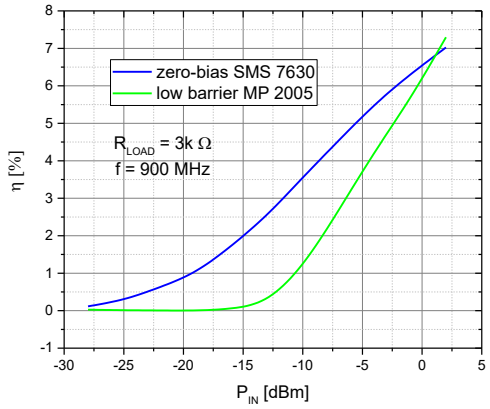

Fig. 9. Comparison of efficiency of SMS 7630 and MP 2005 diodes. Efficiency was measured for load resistance R_{LOAD} = 3 kΩ, and at 900 MHz frequency.

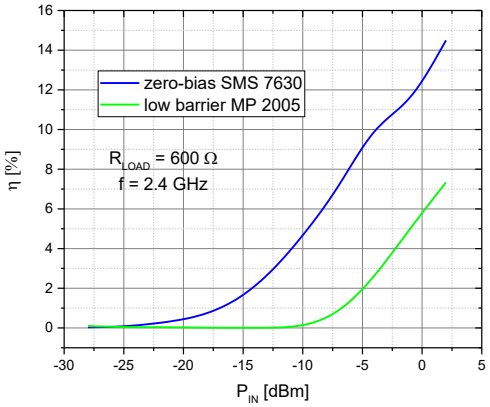

Fig. 10. Comparison of efficiency of SMS 7630 and MP 2005 diodes. Efficiency was measured for load resistance R_{LOAD} = 600 kΩ, and at 2.4 GHz frequency.

III. Conclusion

This paper presents the measurement procedure and obtained results of rectifying Si Schottky barrier diodes that are planned to be used for power harvesting application. As expected, measured results confirm that the low barrier diode MP 2005 is less sensitive than zero-bias diode SMS 7630 in the almost whole applied power range (from -28 to 2 dBm). At a higher frequency range, above 0.9 GHz, the low-barrier diode exhibits even much lower efficiency in respect to the zero bias one. Measured impedance of the diodes are quite similar, which means they can be used with the same antenna, that is designed to have an input impedance complexly conjugate in relation to the rectifying diode.

VHF Gysel 3 dB Power Divider/Combiner in Microstrip Technology

Veljko Crnadak, *Member, IEEE,* and Siniša Tasić

***Abstract*—In this paper, the theory and the design of the VHF Gysel 3 dB power divider/combiner are presented. The Gysel 3 dB power divider/combiner is designed as a microstrip circuit, for the frequency range from 150 MHz to 200 MHz, with the central frequency at 175 MHz. The Gysel divider/combiner is realized as a microstrip circuit on Rogers 4003 substrate, with the copper traces. Knowledge of the conditions, which must be satisfied by the Gysel divider/combiner, enables the determination of the dimensions of the Gysel divider/combiner, through the process of computer simulation. In order to verify the project, values of the S-parameters of the simulated Gysel divider/combiner are compared to the measured values of the S-parameters of the produced Gysel divider/combiner.**

***Index Terms*—combiner; divider; even mode; Gysel; microstrip; odd mode; Rogers 4003; VHF; Wilkinson.**

I. Introduction

A two-way power divider/combiner can split an RF signal into two paths. In reverse direction, it can combine two signals onto a single path. There are two types of power dividers/combiners, resistive ones, and reactive ones. A resistive two-way power divider/combiner has a nominal insertion loss of 6 dB, while a reactive one has a nominal insertion loss of 3 dB. Isolation between input/output ports in a resistive divider/combiner is 6 dB, while in a reactive one is typically 20 dB. If we want to combine outputs of two or more power amplifiers we must use reactive power combiners. The two most famous members of a reactive power divider/combiner group are Wilkinson and Gysel power dividers/combiners. The Wilkinson 3 dB power divider/combiner, Fig. 1, has one crucial drawback and that is its 100 Ω lumped resistor. The lumped resistor has to be small compared to the wavelength, so it is difficult to produce it at high frequencies, and it is problematic to heat-sink it because of its balanced nature [1]. In his design, Gysel swapped the lumped resistor with a network of transmission lines and two 50 Ω ballast resistors. The Gysel 3 dB combiner is used to combine the outputs of two amplifiers in order to obtain a high-power amplifier because proper heat sinking of the external ballast resistors is achievable [2]. The purpose of the paper is to show the differences that arise when realizing the Gysel divider/combiner in microstrip technology, compared to strip-line technology that was implemented in the previous work [3].

Siniša Tasić is with the Company for Microwave and Millimeter-Wave Techniques and Electronics IMTEL-Komunikacije Joint-Stock Company Belgrade, Bulevar Mihajla Pupina 165b, 11070 Novi Beograd, Serbia (e-mail: tasa@insimtel.com).

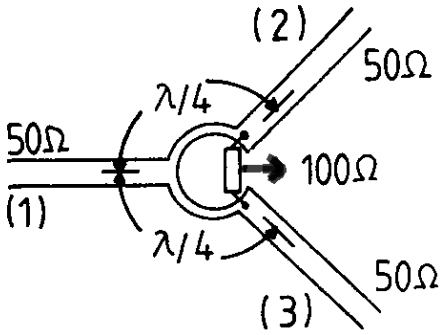

Fig. 1. The Wilkinson 3 dB power divider/combiner [1].

II. Design Theory

The Gysel 3 dB power divider/combiner circuit is shown in Fig. 2.

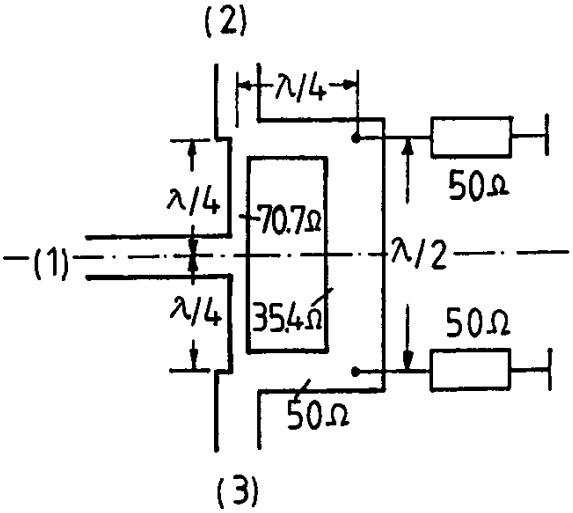

Fig. 2. The Gysel 3 dB power divider/combiner [1].

Port 1 is connected via transmission-line of arbitrary length and the characteristic impedance of 50 Ω, with the rest of the

divider/combiner. Lengths of all transmission-lines in Fig. 2, are determined at the center frequency of the divider/combiner's bandwidth. Two transmission-lines, each a $\lambda/4$ long and with the characteristic impedance of 70.7 Ω, lead from the input port to the two output ports. Two transmission-lines, each a $\lambda/4$ long and with the characteristic impedance of 50 Ω, connect each ballast resistor with its corresponding output port [4]. The two ballast resistors are connected via transmission-line, a $\lambda/2$ long and with the characteristic impedance of 35.4 Ω. Ports 2 and 3 are connected, each via transmission-line of arbitrary length and the characteristic impedance of 50 Ω, with the rest of the divider/combiner. The ballast resistors, 50 Ω each, can be replaced by a transmission-line of the characteristic impedance of 50 Ω, arbitrary in length and terminated in a load of value 50 Ω [4]. Therefore, each ballast resistor has been substituted with an external load, that can sustain high-power. The loads are no longer the power-limiting factor, while the breakdown voltage of the divider/combiner's microstrip lines is the limiting factor [4]. External loads also provide high-isolation between input/output ports. The function of the Gysel 3 dB divider is to divide an input signal into two equal outputs (equal by phase and amplitude). In the reverse direction, the Gysel 3 dB divider works as a combiner, that is it combines two in-phase signals into an output signal. The scattering matrix of an ideal Gysel 3 dB divider/combiner is [3],

$$S = -\frac{j}{\sqrt{2}}\begin{pmatrix} 0 & 1 & 1 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}. \quad (1)$$

The total power that is dissipated on the external loads of the Gysel 3 dB combiner is,

$$P_{tot} = \frac{1}{2}(P_2 + P_3) - \sqrt{P_2 P_3}\cos(\Delta\varphi_{23}), \quad (2)$$

where P_2 and P_3 are the input powers, while $\Delta\varphi_{23}$ is the phase difference between the signals at the input ports.

Because the Gysel power divider/combiner is symmetrical with respect to port 1, we can apply the bisection theorem, that is we can analyze the circuit in the even and the odd mode. The equivalent circuit for the even mode is shown in Fig. 3.

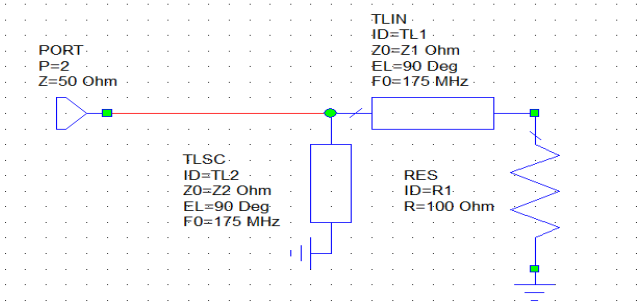

Fig. 3. The equivalent circuit for the even mode.

As Fig. 3 shows, the transmission-line with the characteristic impedance Z_1, behaves as a $\lambda/4$-impedance transformer, while the transmission-line with the characteristic impedance Z_2, behaves as a short-circuited $\lambda/4$-stub. The equivalent circuit for the odd mode is shown in Fig. 4.

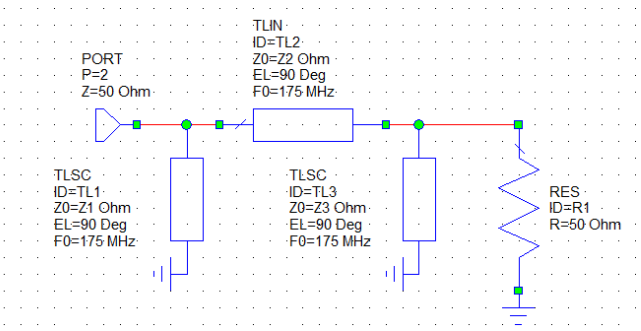

Fig. 4. The equivalent circuit for the odd mode.

As Fig. 4 shows, the transmission-lines with the characteristic impedance Z_1 and Z_3 behave as short-circuited $\lambda/4$-stubs, while the $\lambda/4$-transmission-line that connects them, with the characteristic impedance of Z_2, behaves as an impedance inverter. The circuit in Fig. 4, acts as a band-pass filter of the second order. The basic coupling between the circuits in Figs. 3 and 4 is done through the transmission-lines Z_1 and Z_2 [1]. The Gysel 3 dB power divider/combiner is realized as a microstrip circuit on 1.52 mm thick Rogers 4003 substrate with a relative dielectric constant of ε_r =3.55, and with copper traces 35 μm thick. The width of every input/output line is 3.36 mm. The length of the line that connects port 1 with the rest of the circuit is 5 mm. Both ports 2 and 3 are connected with the rest of the circuit, via the transmission-line of the length 29.5 mm. The width of both lines with the impedance Z_1, 66.87 Ω, is 2.02 mm and the length is 282.63 mm. The width of both lines with the impedance Z_2, 49.76 Ω, is 3.39 mm and the length is 290.6 mm. The width of the line with the impedance Z_3, 23.76 Ω, is 9.62 mm and the length is 565.52 mm. The width of both lines that are connected to the external loads is 3.36 mm and the length is 31.18 mm. The three SMA connectors are mounted on the circuit. The picture of the fabricated Gysel 3 dB power divider/combiner is shown in Fig. 5. The dimensions of the circuit, in Fig. 5, are 190 mm x 102 mm.

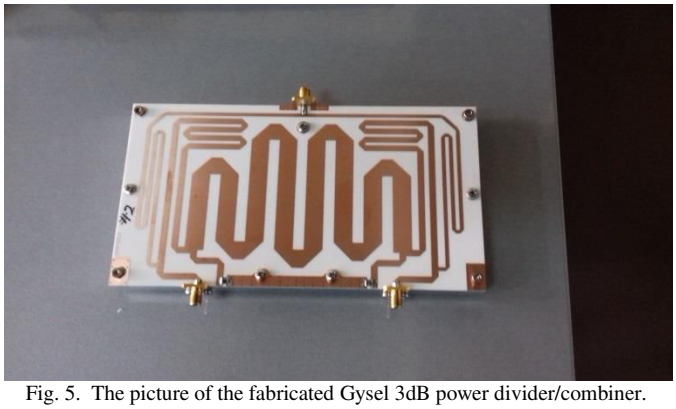

Fig. 5. The picture of the fabricated Gysel 3dB power divider/combiner.

III. Simulation And Measurement Results

A. Simulation

The circuit in Fig. 3 behaves as a resonator with two degrees of freedom, Z_1 and Z_2. In this case, by tuning the impedances Z_1 and Z_2, we can only achieve one zero of the reflection coefficient S_{22} at the center frequency, as it is shown in Fig. 6.

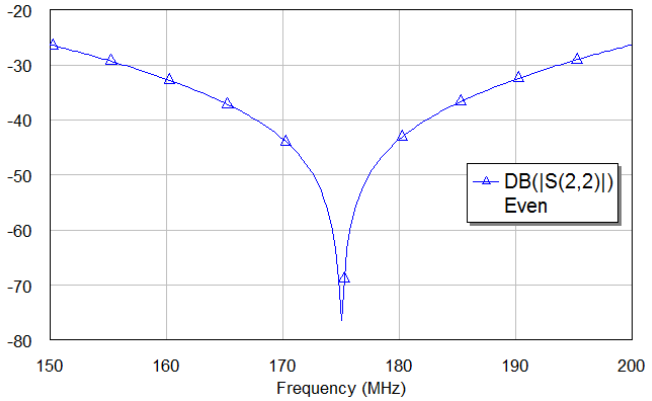

Fig. 6. The reflection coefficient S_{22} in the even mode.

On the other hand the circuit in Fig. 4, behaves as a resonator with three degrees of freedom, Z_1, Z_2 and Z_3. By tuning the impedances Z_1, Z_2 and Z_3, we can achieve two zeros of the reflection coefficient S_{22}, Fig. 7, which increases the bandwidth of the Gysel divider/combiner.

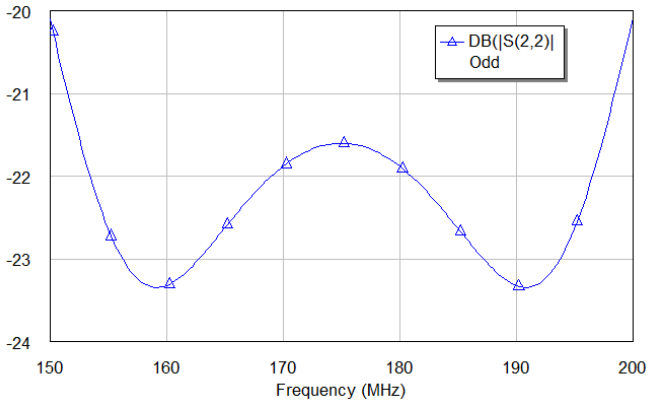

Fig. 7. The reflection coefficient S_{22} in the odd mode.

Having been aware of the conditions, which had to be met by the Gysel power divider/combiner (S_{11}, S_{22}, S_{33} and S_{23}, lower than -20 dB, and S_{12}, S_{13}, lower or equal than -3 dB), we were in the position to direct the optimization process towards satisfying those same conditions, and obtaining the dimensions of the Gysel divider/combiner. The top view of the model of the Gysel 3 dB divider/combiner in MWO Axiem simulator, is given in Fig. 8.

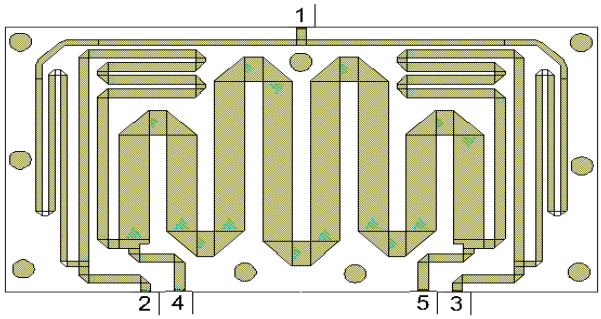

Fig. 8. The top view of the model of the Gysel divider/combiner in MWO Axiem simulator.

B. Simulated and measured results

Figure 9 shows that the measured reflection coefficient S_{11} is lower than -21.1 dB, over the frequency band of interest. The measured reflection coefficient S_{22} is lower than -24.78 dB, over the frequency band of interest, as can be seen in Fig. 10. Figure 11 shows that the measured reflection coefficient S_{33} is lower than -24.88 dB, over the frequency band of interest. The measured isolation S_{23} is lower than -17.65 dB, over the frequency band of interest, as can be seen in Fig. 12. Insertion loss is equal or lower than 3.191 dB and the amplitude balance is ±0.014 dB, over the frequency band of interest, as can be seen in Fig. 13 and Fig. 14. In Fig. 15 we can see that the phase angles of S_{12} and S_{13} are practically the same, over the frequency band of interest.

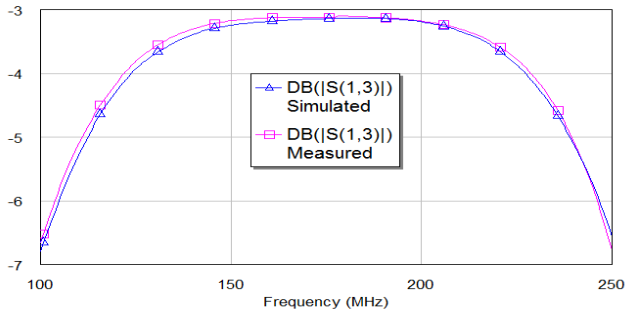

Fig. 14. Comparison of the simulated and measured magnitude of S_{13}.

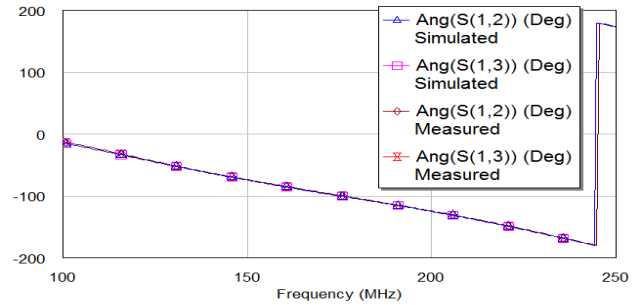

Fig. 15. Comparison of the simulated and measured phases of S_{12} and S_{13}.

IV. Conclusion

In this article, we have described the theory and the design of the VHF Gysel 3 dB power divider/combiner. The objectives regarding the level of the return loss on all three ports, the level of the insertion loss and the level of isolation between the input/output ports were met. The bandwidth of the realized Gysel divider/combiner is 28.57 %. The main advantages of the Gysel 3dB divider/combiner are external isolation loads (permitting high-power loads), easily realizable geometry and monitoring capability for imbalances at the output ports [4]. Microstrip technology favors substantially lower dimensions of the circuit, but higher losses, while strip-line technology provides the capability of handling high-power signals, in the continuous wave mode, at the cost of larger dimensions of the circuit.

EM Modelling of Microstrip T-Junction with an Open Stub Printed over a Dielectric Cylinder

Tomislav Milošević, Dusan Nešić, *Member, IEEE*

***Abstract*—This paper presents EM modelling of microstrip T-junction with open stub printed over a dielectric cylinder. Software tool used for modelling and simulations is a full 3D EM Method-of-Moments, Surface Integral Equation solver applied to quadrilateral mesh elements. The paper investigates the stability of simulation results with respect to various parameters. This includes settings of the numerical kernel, quality of cylindrical surface approximation using segments of bilinear surfaces, different modelling of microstrip edge effects, and comparison between various excitation configurations with and without de-embedding. The purpose of this comprehensive investigation was to establish the optimum calculation parameters for the case of the particular resonator structure. With the optimum parameter settings, the high numerical efficiency of the calculations has been confirmed.**

***Index Terms*—EM modelling, geometrical modelling, microstrip T-junction, open stub, simulation.**

I. Introduction

IN the last couple of decades, electromagnetic (EM) modelling has become a standard process in research and development of various microwave devices. The analytical methods for analysis of such structures are limited to several simple cases. For realistic, complex devices only numerical solutions are adequate. Tremendous efforts have been made to develop efficient tools for versatile, yet intuitive geometrical modelling and efficient numerical analysis of various classes of real-world EM devices. The structures of interest include antennas, scatterers, passive microwave circuits etc. The main requirement for a numerical method suitable for the analysis of such structures is to accurately determine the distribution of the electromagnetic field, currents and charges. Such an analysis is often referred to as the electromagnetic modeling.

Within electromagnetic modeling, various structures can be treated following similar guidelines. For example, passive microwave circuits, such as microstrip transmission lines, usually represent structures consisting of metallic and dielectric parts collectively referred to as composite metallic and dielectric structures. If all the parts are made of linear materials, analysis can be facilitated in the frequency domain [1]. In this paper, we exploited WIPL-D Pro, a full wave, 3D EM frequency-domain Method-of-Moments (MoM) based code for geometrical modelling and simulation which applies higher order basis functions (HOBFs) on quadrilateral mesh elements using Surface Integral Equations (SIE) [4].

Dušan Nešić is with Centre of Microelectronic Technologies, Institute of Chemistry, Technology and Metallurgy, University of Belgrade, Njegoševa 12, 11000 Belgrade, Serbia (e-mail: nesicad@nanosys.ihtm.bg.ac.rs).

Tomislav Milošević is with WIPL-D d.o.o., Gandijeva 7, 11073 Belgrade, Serbia (e-mail: tomislav.milosevic@wipl-d.com).

The stability of output results is usually checked by manually varying numerical kernel parameters. In addition, the influence of some other parameters of interest for EM modelling can be investigated for optimum numerical efficiency.

The geometrical modeling assumes drawing a composite metallic and dielectric structure combining available building elements, bilinear surfaces – plate entities, and wire entities. The modeling can in general be exact or approximate. In the particular case of geometry modeling considered here, the modeling of curved\cylindrical structures is approximate and a search for an acceptable approximation basically involves finding a minimum number of straight segments to approximate curved\cylindrical geometry [1].

The microstrip structures are widely used in microwave engineering. Usually, standard microstrip devices are planar and easily modeled. However, in some applications, the basic microstrip structure can be modified and the properties of a modified structure exploited for a particular advantage, as a structure described in [3]. This paper focuses on EM modelling of a modified, not strictly planar microstrip structure which represents fluid sensors and can be used in measurements of a fluid characteristics [2,3].

The model considered here is a non-strictly planar microstrip structure operating between 0.4 GHz and 4.0 GHz. It is a T-junction which is suitable to be used as a fluid sensor. The results of various simulations are presented and explained.

II. Geometrical Model

The particular T-junction structure with an open stub over the dielectric cylinder is shown in Fig. 1 The dimensions of the parts are indicated in the same figure. The structure has been modeled using one symmetry plane named (A)Symmetry. (A)Symmetry represents a software feature where a symmetry of the structure is exploited to reduce an original number of unknowns. The original number of unknowns is approximately halved. With the feature made active, the numerical kernel is automatically invoked two times and the results are automatically combined.

In order to efficiently control meshing of cylindrical areas, software built-in objects Body-of-Rotation (BoR) were used (Fig. 2). Finite metallization thickness (Fig. 2) is also added using software built-in manipulation. All dimensions of the structure are parametrized through the symbolic variables and can be changed easily.

To optimize numerical accuracy, the resonator structure was modeled by introducing ‘imaging’ where necessary (Fig. 2). This means that closely located ‘upper’ and ‘lower’ surfaces from the model are meshed in the same way. This improves the stability of MoM matrix.

The dielectric substrate is with the following parameters: dielectric constant is 3, while loss tangent is 0.01. Dielectric constant of a lossless cylinder is 10. The cylindrical dielectric in the interior of the structure and the neighboring conductors are shown in Fig. 3.

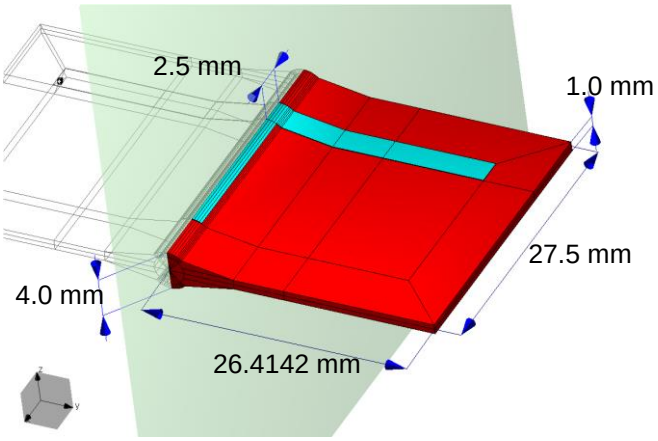

Fig. 1. Simulated structure with overall dimensions and one symmetry plane.

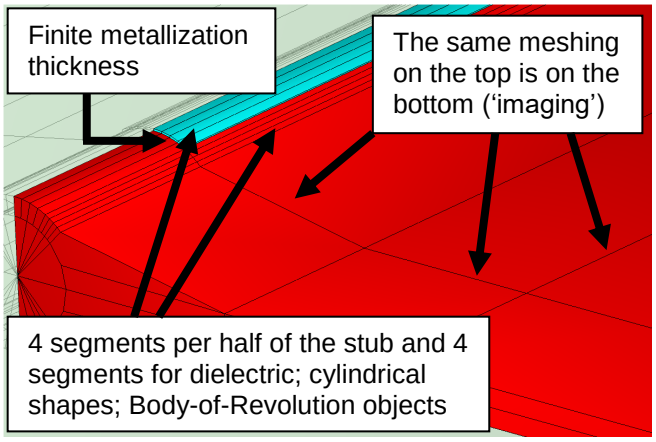

Fig. 2. Simulated structure-the detail. Body-of-Revolution objects modelling curved cylindrical surfaces, finite metallization thickness, and meshing lines on the 'upper' surface can be recognized.

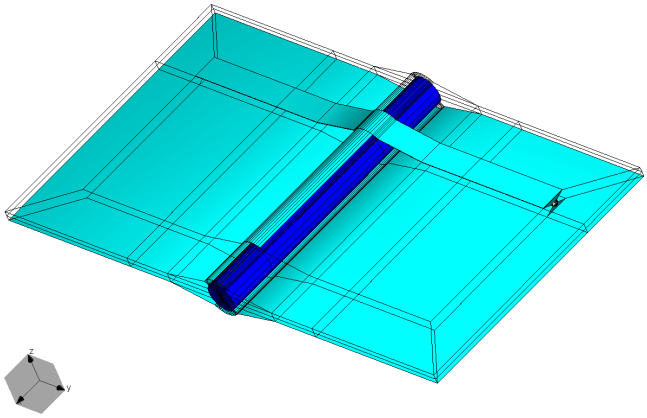

Fig. 3. The cylindrical dielectric and neighboring conductors in the full model without the symmetry applied.

Improved handling of edge effects in particular MoM SIE based software was achieved by automatic subdividion of the plates having a common edge which in fact separates areas belonging to different materials. The automatic subdivision follows after applying, so called, Edge-ing manipulation. Details of modified structure are in Fig. 4.

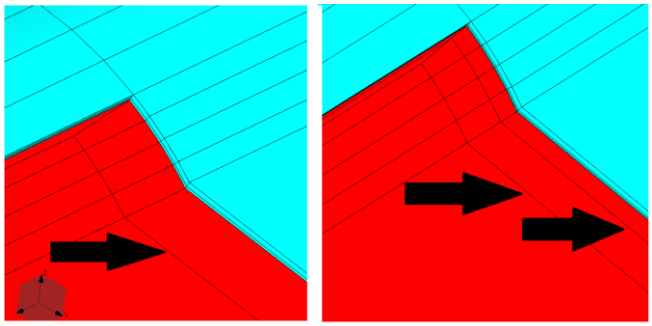

Fig. 4. Handling of edge effects – the pre-simulated structure modification after application of single Edge-ing and double Edge-ing manipulations.

The location of the reference plane required for the de-embedding and position of generator used for feeding are shown in Fig. 5.

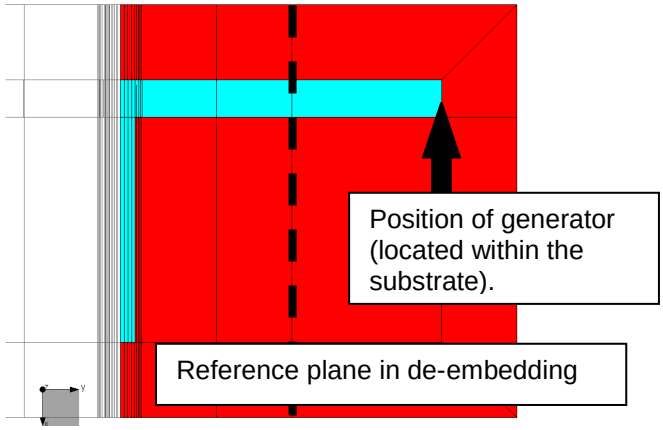

Fig. 5. Reference plane defined in the de-embedding process and position of the generator used for feeding.

III. Simulation Results

In order to demonstrate EM modelling of the structure, to highlight the most important steps in the investigation of this, and to discuss some actions required in usual EM modeling, we present here S-parameters from several simulation scenarios. At first instance, we investigate the convergence of the simulations by varying standard calculation parameters. After that we investigated influence of a number of bilinear surface segments used in cylindrical objects modelling. The quality of edge effects modelling was investigated next. Finally, the results obtained with and the results obtained without the de-embedding are compared.

All of the models have been simulated at 21 frequency points. The smooth curves are resulting from excellent graphical fitter used. All of the models were simulated on standard Intel® Core™ i7-7700 CPU @ 3.60 GHz with 64 GB RAM. The most time-consuming simulation is the one where a model of the structure includes Edge-ing manipulation applied two times (total simulation time is 900 seconds). The most of the other simulations finish after

500 seconds - 850 seconds.

A. *Obtaining Optimally Stable Results*

Convergence check was performed by manually varying numerical kernel parameters. The first step was increasing parameter Integral accuracy (IA) from *normal* to *Enhanced 1* and graphically comparing the responses obtained (Fig. 6). Parameter IA influences evaluation of integrals related with accurate calculation of MoM matrix elements. In general, higher IA enables more accurate results, exploiting longer simulation time. Results obtained after IA set to *normal* and set to *Enhanced 1* are denoted as IA = 0 and IA = 1, respectively.

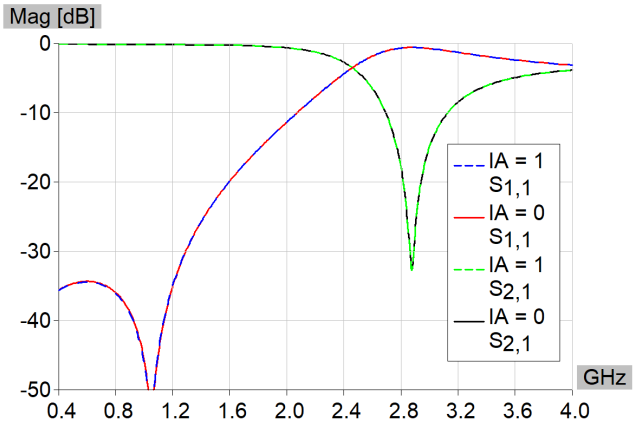

Fig. 6. S-parameters with Integral accuracy parameter varied.

The effect of increasing a number of unknowns has been investigated next. The number of unknowns represents the number of unknown coefficients used for current distribution approximation. Comparison of the results is shown in Fig. 7 and Fig. 8.

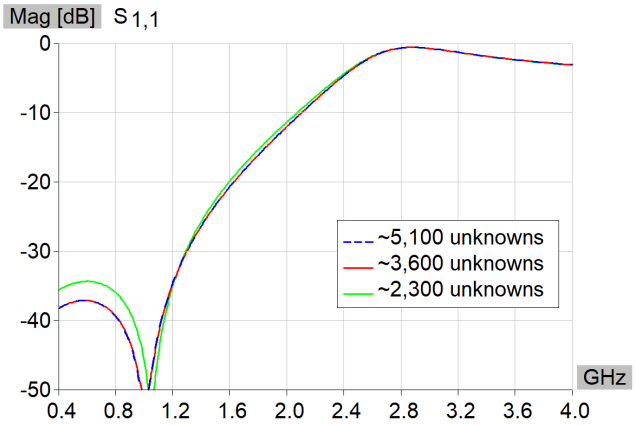

Fig. 7. S_{11}-parameters obtained for varied number of unknowns.

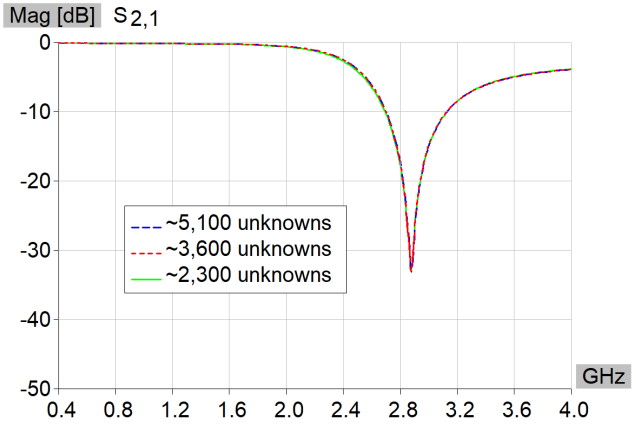

Fig. 8. S_{21}-parameters obtained for varied number of unknowns.

A tradeoff between sufficient accuracy and minimum computer resources required suggests that a value for the integral accuracy should be set to *normal* with a number of unknowns set to 3,600.

B. *Bilinear Segments Used in Cylindrical Surfaces Modelling*

Cylindrical objects are approximated using planar bilinear surfaces, as in BoR objects shown in Fig. 2. As a next step towards establishing the optimum calculation parameters, a number of segments is varied and the influence of changing number of segments to the results investigated. Results with various numbers of segments determining stub curvature and dielectric curvature are shown in the Fig. 9 and Fig. 10, respectively. A quality of approximation using a total of 12 and 8 segments was investigated for the case of a stub curvature, while a total of 6 and 4 segments were used for modelling the dielectric curvature.

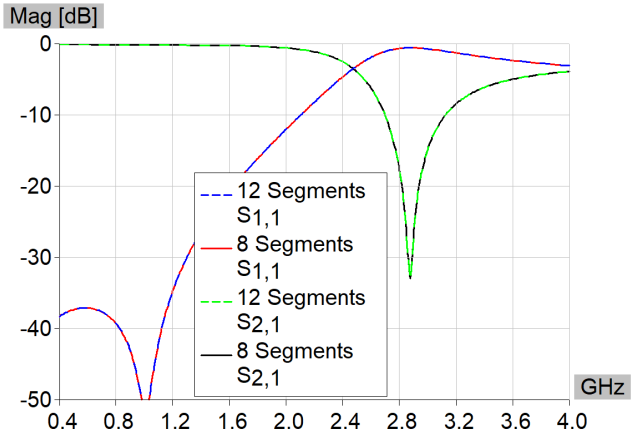

Fig. 9. S-parameters for varied number of segments of the Body-of-Revolution object modelling stub curvature.

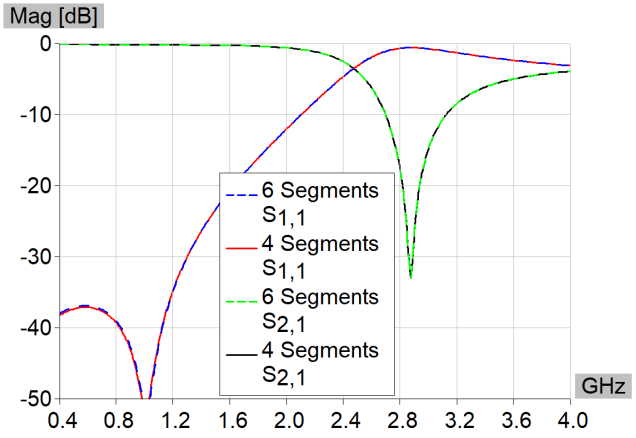

Fig. 10. S-parameters for varied number of segments of the Body-of-Revolution object modelling dielectric curvature near stub.

C. *Investigating Edge Effects*

According to the recommendations for the particular software used for the simulations, at least one Edge-ing manipulation (Fig. 4) should be used for microstrip and microstrip-like structures. Following the recommendations, in the analysis of the model of the structure with IA set to *normal* requiring 3,600 unknowns, which S-parameters are shown in Fig. 7 and Fig. 8 one Edge-ing manipulation has been used already. However, the influence of Edge-ing manipulation to the accuracy of the simulations is investigated as follows. The S-parameters obtained without Edge-ing are compared with results with one Edge-ing manipulation applied and with two Edge-ing manipulations applied. The results are shown in Fig. 11.

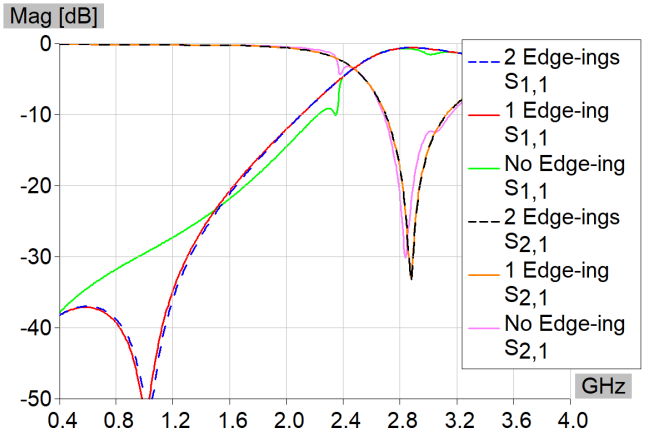

Fig. 11. S-parameters for models where Edge-ing manipulation is not applied with models where one and two manipulations Edge-ing are applied.

D. *The Influence of De-Embedding Procedure*

In the simulations presented so far, S-parameters are calculated with respect to the reference plane coinciding with the location of the generators. In order to calculate S-parameters in reference planes presented in Fig. 5, the De-embedding technique is applied. The comparison between S-parameters obtained after De-embedding procedure applied and the simulation without de-embedding procedure are shown in Fig. 12.

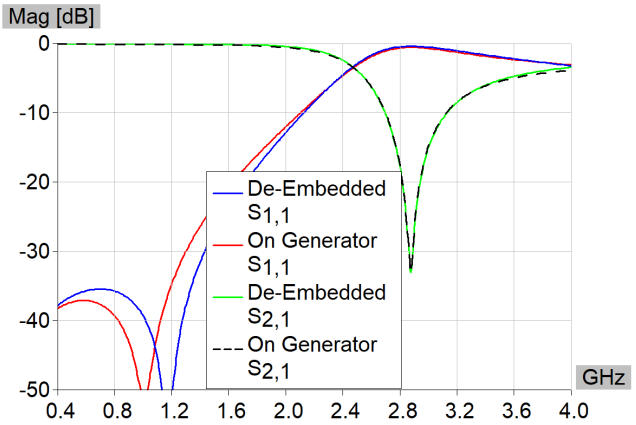

Fig. 12. De-embedded S-parameters and S-parameters calculated without -embedding, on the generators.

IV. Conclusion

This paper presented EM modelling of microstrip T-junction with open stub printed over a dielectric cylinder. Software tool used for modelling and simulations was a full 3D EM Method-of-Moments, Surface Integral Equation solver applied to quadrilateral mesh elements.

The paper investigates the stability of EM simulation results with respect to various parameters: settings of the numerical kernel through changing parameters of a numerical integration and a number of unknowns required, quality of approximation of cylindrical surfaces, different modelling of microstrip edge effects, and comparison between various excitation configurations with and without de-embedding.

The investigation of EM modeling of the structure was established in order to reveal optimum simulation parameters for the case of the particular resonator structure which modification can act as a real-life sensor for fluid measurement. With the optimum parameter settings, the high numerical efficiency of the calculations has been confirmed. It has been shown that, with proper EM model, even with the standard settings applied to control the operation of the numerical kernel, the utilized software produced very stable S-parameters. The stability has been confirmed as changes in several numerical kernel parameters haven't introduced noticeable changes in S-parameter values. It was shown that quality of approximation of cylindrical structures and stability of S-parameters is high even with relatively small number of linear segments utilized. Also, it has been shown that edge effect has to be properly taken into the account if a non-strictly planar microstrip-like structure is simulated. The edge effect has been conveniently modeled with application of a single Edge-ing manipulation. Finally, we showed that De-embedding procedure is not mandatory if the proper feeding structure is used for excitation of the EM model.

The high efficiency can be confirmed in a different sense - through the simulation times as they are all relatively short. From a practical side this is very significant result as the simulations were carried out on a standard desktop platform.

The further investigation of this structure will include test

sample fabrication and utilization in measurement of various fluid characteristics.

A New Type of Microwave Coaxial Resonant Permittivity Sensor

Dušan Nešić, *Member, IEEE*

***Abstract*—A new type of microwave coaxial resonant permittivity sensor is introduced. It is constructed using only commercial SMA connectors: one T-junction and one jack-to-jack adapter. The complete open stub is formed of a needle (the central conductor) and the hollow jack-to-jack adapter (the outer conductor). The hollow jack-to-jack adapter is container to be filled with the material under test. The sensor is simulated and preliminary measured in a wide dielectric constant range, from 1 to 4 and from 30 to 80.**

***Index Terms*—Microwave sensor, Permittivity measurement, Coaxial resonator.**

I. Introduction

MICROWAVE sensors are becoming a widespread type of sensors [1-3]. Among them permittivity sensors are important in characterization of microwave substrates and other material (gasses, fluids and solids) [2-4]. Resonant method has some advantage as a type of sensing. The resonant method has the lowest uncertainties for the permittivity [2] and the permittivity is determined from measurements of the resonance frequency.

Coaxial structure is the one of the most convenient and frequently used technique to measure lossy materials at high frequencies (i.e RF and microwave). The most common is coaxial probe method which detects reflected signal (phase and magnitude) from the tested material [3]. It is also applicable for fluids but has some disadvantages. The disadvantages are repetitive calibrations, some deflection for the low permittivity materials and cable stability [3,4]. Another coaxial method to measure the dielectric properties of fluids are coaxial open stub resonators [5-8]. This technique is less sensitive to errors especially for outer electromagnetic influence. In all cases in [5-8] systems are for relatively higher amount of fluids, mainly for water monitoring (diameter of open stub part is around 25 mm and length over 250 mm).

Coaxial resonant permittivity sensor presented in this paper is for a small amount of material. It is constructed using only commercial SMA connectors. The applied SMA connectors are one T-junction and one jack-to-jack adapter, Fig. 1. The sensor is fabricated, simulated and preliminary measured in a wide dielectric constant range.

Fig. 1. SMA: a) Jack-to-plug-to-jack Tee adapter; b) Jack-to-jack adapter

Dušan Nešić is with the Centre of Microelectronic Technologies, Institute of Chemistry, Technology and Metallurgy, University of Belgrade, Njegoseva 12, Belgrade, Serbia, (e-mail: nesicad@nanosys.ihtm.bg.ac.rs).

II. Sensor Construction

The presented sensor is constructed of one SMA jack-to-plug-to-jack Tee adapter and one SMA jack-to-jack adapter, Fig. 1a,b. A needle 11mm long is mounted with silver-epoxy on the Tee adapter as a central conductor of the open stub, Fig. 2a. The inner content of the jack-to-jack adapter, Fig. 1b, is removed. Then, the hollow metal cylinder is mounted on the Tee adapter with the needle, Fig. 2a, and forms final structure in Fig. 2b. Now, the complete open stub is formed of the needle (the central conductor) and the hollow jack-to-jack adapter (the outer conductor). The hollow jack-to-jack adapter is filled with fluid to perform measurement.

Fig. 2. a) 11 mm long needle mounted with silver-epoxy on the SMA Tee adapter presented in Fig. 1a ; b) Hollow SMA jack-to-jack adapter, Fig. 1b, mounted on the SMA Tee adapter with a needle presented in a).

III. Simulation and Measurement

Simulation is performed in Program Package WIPL-D Microwave Pro v5.1 for the coaxial structures [9]. The scheme is presented in Fig. 3. Sensing part, needle (the central conductor) and the hollow jack-to-jack adapter (the outer conductor) are presented as the Coaxial open end in Fig. 3.

Simulation results are presented in Fig. 4 for lower real dielectric constant ε_R (1 to 4) and in Fig. 5 for higher ε_R (30 to 80). The lower ε_R includes, for example, gasoline and oils. The higher ε_R includes ethanol, water and their mixture.

Preliminary measurement results are presented in Fig. 6. to Fig. 9. for: air, gasoline, 70% ethanol-water mixture and tap water. According to the simulation results ε_R of gasoline is 1.95 against 2.0 in literature [10]. For 70% ethanol-water mixture is 45 against 39.5 [11]. For the tap water it is 80 against 76 [12]. Obviously, higher ε_R produce higher step in characteristic impedance and high fringing effect.

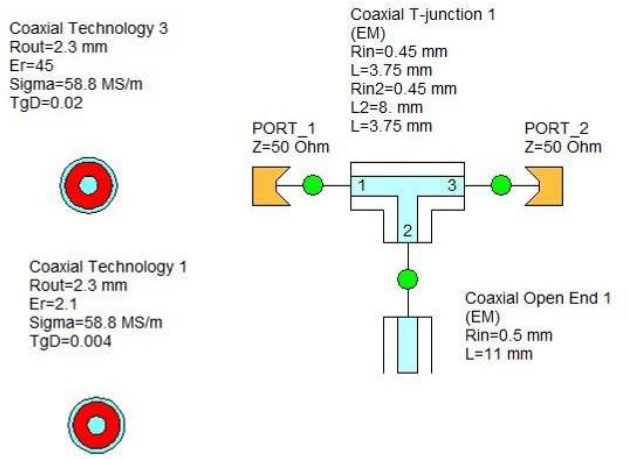

Fig. 3. Scheme of the sensor modeled in Program Package WIPL-D Microwave Prov5.1 for the coaxial structures. Sensing part, needle (the central conductor) and the hollow jack-to-jack adapter (the outer conductor) are presented as the Coaxial open end.

IV. Option of a Differential Sensor

A general drawback of resonance-based sensors is that permittivity depends on environmental conditions (temperature, moisture) and thus the resonance frequency can shifted by spurious effects. Typical solution to deal with changing environmental factors is through differential measurements e.g. differential sensor [13]. Model of the presented sensor applied as a differential sensor is presented in Fig. 10. The graphs in Fig. 11. present an example of simulated S_{21}-parameters for the differential sensor for two pairs of dielectric constants: 2.1 against 2.1 and 2.1 against 2.2.

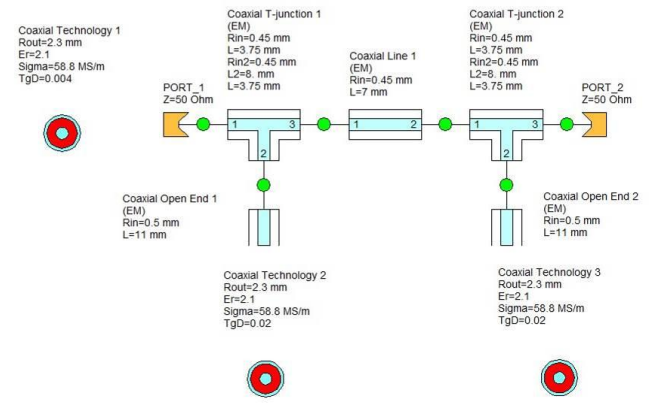

Fig. 10. Scheme of the differential sensor structure simulated in Program Package WIPL-D Microwave Pro v5.1 for the coaxial structures.

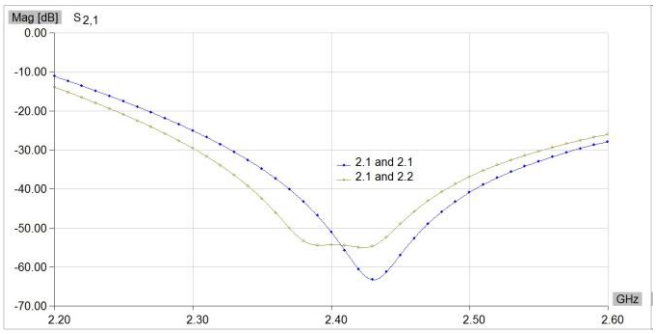

Fig. 11. An example of S_{21}-parameters in simulation of differential sensor for two pairs of dielectric constants: 2.1 against 2.1 and 2.1 against 2.2.

V. Conclusion

This work is introducing a new type of coaxial resonant sensor. It is constructed using only two types of SMA connectors: one SMA jack-to-plug-to-jack Tee adapter and one SMA jack-to-jack adapter. It is easy for construction and useful for smaller amount of fluid under test (cylinder diameter 4.4 mm and to 15 mm high). The sensor is simulated and tested for the wide range of the real dielectric constant, from 1 to 4 and from 30 to 80. High ε_R produces high impedance step and high fringing effect. In future work it needs complete 3D simulation in WIPL-D.

Simulation is also experimentally done for a differential sensor and gives very good results.

Acknowledgment

Author would like to thank L. Novaković, Dr. M. Frantlović and R. Đorđević for help in fabrication and to professor M. Potrebić from the University of Belgrade, School of Electrical Engineering, for her assistance in performing the measurements.

This work was funded by the Serbian Ministry of Education and Science within the project TR 32008.

A Simple Analog Control System for Electromagnetic Levitation Small Object

Nenad Popović[1], Predrag Manojlović[1], and Bojan Virijević[2]

***Abstract*—This paper describes a design of an electromagnetic levitation system for small iron sphere on a small distance from the electromagnet. The control circuit for controlling the distance between the metal ball and the electromagnet consists of a switching electronics with electromagnet and Hall or opto-coupler sensors.**

***Index Terms*—Electromagnetic Levitation, Feedback Control circuit, Opto-Coupler Sensor.**

I. Introduction

A magnetic levitation system is one of the most popular systems in levitation control of small objects.

Electromagnetic levitation is a method by which a metal object (ferromagnetic) floats with the aid of a magnetic field. It uses the electromagnetic force to neutralize the effect of the gravity on the object. In other words, a stable leap of the object in the field of gravity. In real-time, the system responds predictably to unpredictable external influences [1] - [9].

The control of the floating object is usually carried out either via an optical sensor or through a Hall sensor. The Hall sensor solution is mechanically simpler [4].

The first practical application in the field of public transport was applied at the MAGLEV's Shanghai-run railroad in length of 30 kilometers, connecting the Shanghai center and the new Shanghai Pudong airport [7].

II. Phisical Model

The mathematical model of this system is based on the physical model encompasses actuator, electromagnet and metal ball. Electromagnet acts with its electromagnetic attraction force on a metal ball, attracting it against the opposite effect of its weight.

The electromagnetic levitation model can be viewed as a feedback control system [1], the basic block diagram which is shown in Figure 1.

Nenad Popović[1] is with IMTEL Komunikacije a.d., Belgrade, Bulevar Mihaila Pupina 165b, 11070 N. Belgrade, Serbia (e-mail: nenad@ insimtel.com).

Predrag Manojlović[1] is with IMTEL Komunikacije a.d., Belgrade, Bulevar Mihaila Pupina 165b, 11070 N. Belgrade, Serbia (e-mail: pedja@ insimtel.com).

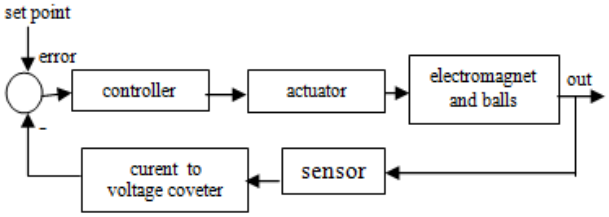

Figure 1. Functional block diagram of the levitation device.

III. Mathematical Dynamic Model

Figure 2 shows the graphic model of the electromagnetic actuator and the metal ball with the forces acting on it [1], [2].

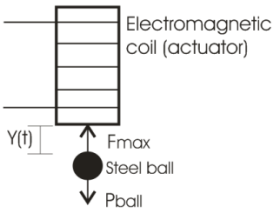

Figure 2. The ball weight is equilibrated by the magnetic force.

The system of mathematical equations for the modelthat is shown in Figure 2, can be written in the following way.
In static equilibrium, it is given by the equation (1) [1],[2].

$$Fmag = Pball = mg \tag{1}$$

m - The steel ball weight
g - 9.81 $[\frac{m}{s^2}]$

Dynamic behavior of the model can be described with equation (2).

$$F_R = F_{mag}^{din} - P_{ball} = m\frac{d^2y(t)}{dt^2} \tag{2}$$

the acceleration is: $a = \frac{d^2y(t)}{dt^2}$ (3)

The dynamic electromagnetic force is given by sum of the static component that compensates for the weight of the steel ball and the variation of the magnetic force, as shown by equation (4).

$$F_R = F_{mag} + \Delta F_{mag} - P_{ball} = m\frac{d^2y(t)}{dt^2} \quad (4)$$

In accordance with equation (1), static equilibrium, the electromagnetic force equals the weight of metal balls ($F_{mag} = F_{ball}$). Thus, these two forces in equation (4) can be mutually canceled so that the result is now given by the following expression (5):

$$F_R = \Delta F_{mag} = m\frac{d^2y(t)}{dt^2} \quad (5)$$

y - distance from electromagnet to ball

We can also calculate the results and observe the energy equilibrium, which in this case includes electrical influences:

$$dW_e = dW_{meh} + dW_t + dW_M \quad (6)$$

where are:
dW_e - total energy
dW_{meh} - mechanical energy
dW_t - heat energy
dW_M - magnetic energy

Through electromagnetic energy we can achieve an attractive electromagnetic force F_M [6]:

$$F_M = -\left[\frac{\partial W_M}{\partial y}\right] i - cost \quad (7)$$

$$W_M = \frac{L(y)\, i^2}{2} \quad (8)$$

where inductance L (y) is given by the following expression [3].

$$L(y) = Lo + L_1 e^{-(\frac{y}{y_0})^2} \quad (9)$$

L_0 - electromagnetic inductance without the presence of balls,
L_1 - electromagnetic inductance with ball presence,

now equation is:

$$-\left[\frac{\partial W_M}{\partial x}\right]_{i-const} = -\frac{\partial L(y)}{\partial y}\frac{i^2}{2} =$$
$$-\frac{\partial}{\partial y}\left(L_0 + L_1 e^{-\left(\frac{y}{yo}\right)^2}\right)\frac{i^2}{2} =$$
$$-L_1\frac{\partial}{\partial y}\left(e^{-\left(\frac{y}{yo}\right)^2}\right)\frac{i^2}{2} =$$
$$-L_1\frac{i^2}{2}\left[-2\left(\frac{y}{yo^2}\right)e^{-\left(\frac{y}{yo}\right)^2}\right] =$$
$$L_1 i^2\left[\left(\frac{y}{yo^2}\right)e^{-\left(\frac{y}{yo}\right)^2}\right] \quad (10)$$

So F_M is the same:

$$F_M = -\left[\frac{\partial W_M}{\partial x}\right] i - cost = L_1 i^2\left[\left(\frac{y}{yo^2}\right)e^{-\left(\frac{y}{yo}\right)^2}\right] \quad (11)$$

The inductance of the electromagnet windings depends on the position of the metal ball. The balloon can have two end positions, one when it touches the electromagnet core and the other when it is away from it.

In the expression (11), y_0 has a constant value so that the variable is part of the expression of the scaling can be written in the form of function $f(y) = ye^{-y^2}$, whose graphic representation [10] is given in Figure 3. Note that value of y = 0 to y = 3 is an interesting part for us.

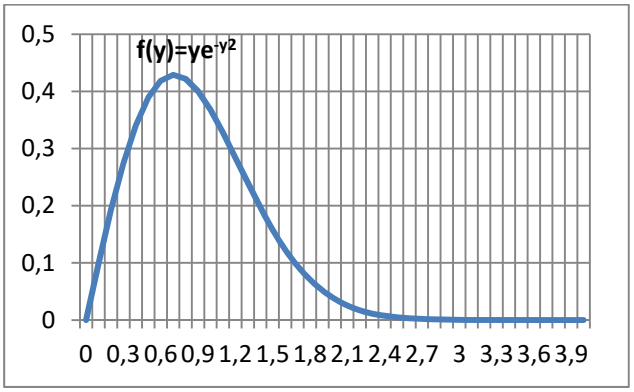

Figure 3. Graphic function $f(y) = ye^{-y^2}$.

By applying Laplace transform to the expression (10) in the time domain, we can calculate its corresponding shape in the frequency domain [1-3].

$$\mathcal{L}\left[L_1 i^2\left(\frac{y}{yo^2}\right)e^{-\left(\frac{y}{yo}\right)^2}\right] \quad (12)$$

For equation,

$$L_1 i^2 \mathcal{L}\left[\left(\frac{y}{yo^2}\right)e^{-\left(\frac{y}{yo}\right)^2}\right] \quad (13)$$

we get the following expression [10]:

$$L_1 i^2 \frac{1}{4}[2 - e^{\frac{s^2}{4}}\sqrt{\pi}\, s\, \mathrm{Erfc}(\tfrac{s}{2})] \quad (14)$$

where,

Erfc[z] – is a complementary error function

IV. REALIZATION

An electromagnet with a corrugated core is attached to an aluminum yoke that is attached to a fiberglass stand, which also has a circular circuit breaker. Electromagnet has the following characteristics:

$$L = 73.2 \text{ mH}, N = 1300 \text{ winds}, r = 17.5\ \Omega.$$

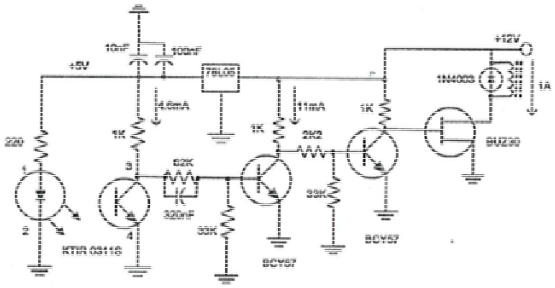

Figure 4. Shematic diagram of realized control circuit for electro-magnetic levitation.

Intesity of coil current is controled by signal of opto-coupler placed nearby sensor plane. Switching electronics operate very efficiently and allow stabile position of the iron rod. Design of controler unit is very simple because we have only two possible states of the opto-coulper output.

Figure 5 shows a photo of a realized model for electromagnetic levitation with switching electronics.

Figure 5. Photo of a realized yoke for electro-magnetic levitation.

V. CONCLUSION

The device function was tested in laboratory conditions and the operating area was established. An area where exist the stable behaviors of the levitating object with assigned weight is guaranteed. The system gain was experimentally checked for defined weights. Levitation of an object is the basic form of electromagnetic levitation creating an opportunity to be familiarized with all the fundamental aspects of control system and electromagnet theory. Implemented design only imposes control in the vertical direction. Electromagnetic levitation system is difficult to implement in 3 dimensions because of its intrinsic nonlinearity.

The force actuator and the sensor can be controled in linearized model by using panoply of coils and sensors instead of single opto-coupler element.

Modelovanje pojačavača snage za LTE sisteme primenom RVTDNN mreže

Jelena Mišić, Milan Čabarkapa, Vera Marković, Đurađ Budimir

***Apstrakt*—U ovom radu predstavljeno je modelovanje izrazito nelinearnih multifrekvencijskih pojačavača snage za širokopojasne LTE sisteme primenom veštačkih neuronskih mreža. Za modelovanje pojačavča korišćena je dinamička neuronska mreža sa kašnjenjem koja ima realne ulazne vrednosti (eng. *Real-Valued Time Delay Neural Network* - RVTDNN). Prilikom modelovanja, ravijen RVTDNN model je optimizovan po broju skrivenih slojeva, neurona u skrivenim slojevima, i dubini memorije ulaznog i izlaznog signala. Metrike koje su korišćene prilikom optimizacije su NMSE (*Normalized Mean-Square Error*) i NAMSE (*Normalized Absolute Mean-Square Error*). Optimalni model ima 12 i 15 neurona u skrivenim slojeva, i dubinu memorije izlaznog signala 3. AM/AM, AM/PM i spektralna karakteristika razvijenog modela na test skupu podataka, koji se razlikovao od trening skupa, imaju visok stepen podudaranja sa odgovarajućim merenim karakteristikama pojačavača.**

***Ključne reči*—ANN; pojačavač snage; LTE; modelovanje komponenti.**

I. UVOD

BROJ mobilnih korisnika je u stalnom porastu poslednjih godina jer je mobilnost postala osobina koja se podrazumeva na polju govorne komunikacije. Takođe, od mobilnih mreža se zahteva da prenesu velike količine podataka za relativno kratko vreme. Trenutna tehnologija koja se koristi u mobilnim mrežama je 4G tehnologija, odnosno LTE (*Long Term Evolution*), koja je dizajnirana da zadovolji zahteve kosinika u pogledu brzine prenosa i količine podataka.

LTE tehnologija podržava fleksibilne opsege učestanosti zahvaljujući primeni OFDMA (*Orthogonal Frequency Division Mulitple Access)* i SC- FDMA (*Single Carrier Frequency Division Multiple Access)* pristupnim šemama. LTE na *downlink*-u koristi OFDMA tehniku višestrukog pristupa, dok na *uplink*-u koristi SC-FDMA.

Jedna od najbitnih komponenti na predajoj i prijemnoj strani LTE sistema je pojačavač snage (eng. *Power amplifier* - PA) osnosno malo-šumni pojačavač (eng. *Low noise amplifier* - LNA). U modernim mobilnim sistemima, kao što su sistemi bazirani na LTE standardu, koriste se napredne modulacione tehnike, kod kojih pojačavač snage radi blizu oblasti saturacije kako bi se postigla maksimalna izlazna snaga. Međutim, u ovoj oblasti prenosna karakteristika pojačavača više nije linearna, što u slučaju primene signala kao što je OFDM signal može dovesti do distorzije.

Jedna od najrasprostranjenihih metoda za linearizaciju pojačavača je DPD (*Digital pre-distortion*) koja se zasniva na uvođenju bloka čija je prenosna krakteristika jednaka inverznoj prenosnoj karakteristici pojačavača koji se koristi. Kao što se može zaključiti, za implementaciju DPD modela neophodno je razviti kako model samog pojačavača tako i njegov inverzni model. Postoji mnogo tehnika za modelovanje mikrotalasnih komponenti. Jedna od trenutno najzastupljnijih tehnika su veštačke neuronske mreže (eng. *Artifical Neural Networks* - *ANNs*) [1]. Veštačke neuronske mreže se primenjuju za modelovanje različitih RF komponenti među kojima su i pojačavači snage [2-5]. Postoji veliki broj tipova ovih mreža i kod modelovanja komponenti je najbitnije odabrati najpogodniji model mreže i prilagoditi njegove parametre komponenti koja se modeluje.

Zbog značaja izbora najpogodnijeg ANN modela, u ovom radu predstavljena je detaljna analiza modelovanja jednog pojačavača, kao i razvijeni ANN model.

Ostatak rada je organizovan na sledeći način. U Sekciji II, predstavljene su veštačke neuronske mreže. U Sekciji III, data je analiza modelovanja i konačni model pojačavača, kao i njegove karakteristike. U Sekciji IV, dati su zaključci i smernice za budući rad.

II. VEŠTAČKE NEURONSKE MREŽE

ANN mreža se može definisati kao paralelna matematička struktura sastavljena od određenog broja jednostavnih, međusobno povezanih elemenata – neurona. Neuroni u ANN su tipično organizovani u slojevima. Jedna ANN mreža može imati različit broj slojeva. Prvi sloj u ANN mreži se naziva ulazni sloj (eng. *input layer*), posle njega sledi jedan ili više skrivenih slojeva (eng. *hidden layers*), nakon kojih je izlazni sloj (eng. *output layer*). Broj neurona u ulaznom sloju jednak je broju nezavisnih ulaznih parametara, dok je broj izlaznih neurona jednak broju parametara koje treba modelovati. Najčešće korišćeni tip ANN mreža je *feedforward* ANN mreža kod koje se signal kreće u smeru od ulaznog sloja ka izlaznom sloju bez ikakvih povratnih signala kroz samu mrežu. Uprošćeni prikaz *feedforward* ANN mreže koja se sastoji od 3 sloja dat je na Sl. 1.

Jelena Mišić – Elektronski fakultet, Univerzitet u Nišu, Aleksandra Medvedeva 14, 18106 Niš, Srbija (e-mail: ms.jelena.misic@gmai.com).

Milan Čabarkapa – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar Kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: cabmilan@etf.bg.ac.rs).

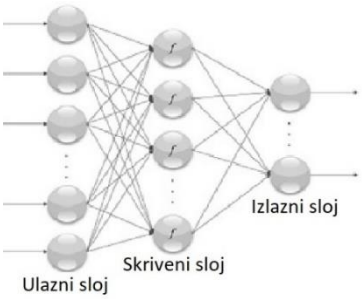
Đurađ Budimir – Wireless Communications Research Group, University of Westminster, London, UK (d.budimir@wmin.ac.uk).



Sl. 1. Uprošćeni prikaz structure troslojne ANN mreže.

Kao što se sa Sl. 1 može videti, neuroni jednog sloja su povezani sa svim neuronima u narednom sloju. Svaki od neurona ANN mreže se karakteriše svojom prenosnom funkcijom i vrednošću bijasa, dok se svaka veza između neurona karakteriše težinskim faktorom. Neuroni u jednom sloju imaju istu prenosnu funkciju. Prenosna (aktivaciona) funkcija predstavlja funkciju koja povezuje ulazni i izlazni signal neurona. Da bi se mreža trenirala da simulira izlaze sa potrebnom preciznošću, pragovi funkcija aktiviranja neurona i težine neuronske veze se optimizuju tokom procesa obuke mreže.

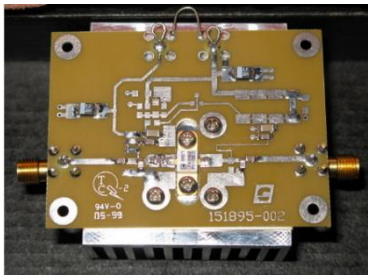
ANN mreže se zbog svoje sposobnosti visoke aproksimacije nelinearnih funkcija, uspešno primenjuju kod modelovanja RF i mikrotalasnih uređaja/kola [6-9]. Teorema uopštene aproksimacije (eng. *Universal Approximation Theorem* - UAT) [10] pokazuje da *feedforward* ANN mreža sa jednim skrivenim slojem i promenljivim, monotono rastućim, kontinualnim aktivacionim funkcijama može da aproksimira bilo koju nelinearnu funkciju sa željenom verovatnoćom greške. Dakle, prema UAT teoremi, struktura sa jednim skrivenim slojem (eng. *Single Hidden Layer* - SHL) je dovoljna za aproksimaciju uniformnog nelinearnog sistema.

III. MODELOVANJE POJAČAVAČA PRIMENOM ANN

Ono što karakteriše pojačavače osim njihove osnovne funckije pojačavanja signala, je i tzv. memorijski efekat koji se oglada u činjenici da izlaz pojačavača zavisi kako od trenutnog ulaza u pojačavač tako i od jedne ili više prethodnih vrednosti ulaznog i izlaznog signala pojačavača. Memorijski efekat je karakteristika koja je vrlo bitna prilikom modelovanja pojačavača. Ukoliko se prilikom modelovanja ne uzme u obzir i memorijski efekat može doći do greške u predikciji izlaza modela, što u krajnjoj liniji dovodi do greške i u DPD modelu, imajući kao krajnji cilj loš efekat linearizacije.

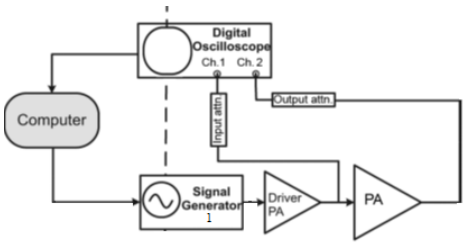
A. Prikupljanje podataka za modelovanje

U okviru ovog rada, mi smo izvršili analizu i modelovanje pojačavača sa oznakom CFH-2163-P3 (*datasheet* je u [8]), koji je prikazan na Sl. 2.



Sl. 2. Pojačavač CFH-2163 P3.

Realni pojačavač je u ovom radu predstavljen svojim matematičkim modelom. Za dobijanje funkcije koja predstavlja matematički model koristili smo laboratorijsku postavku prikazanu na Sl. 3.

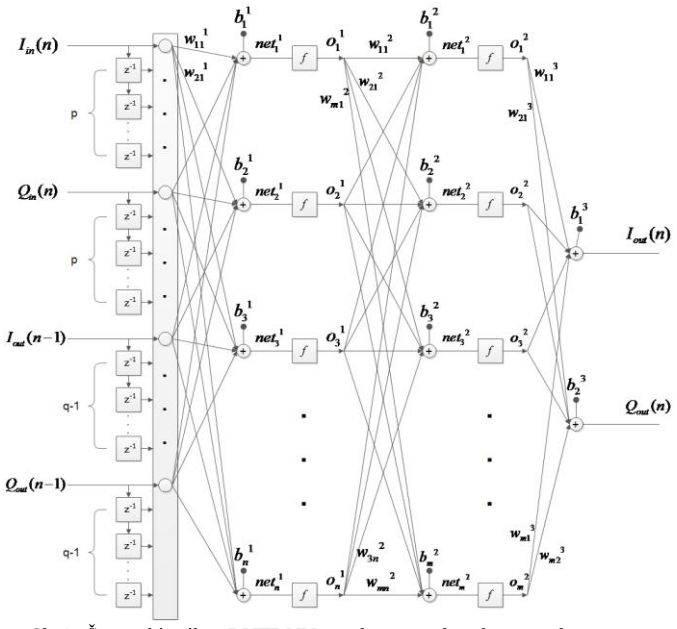


Sl. 3. Postavka za merenje gde PA predstavlja DUT (eng. *Device Under Test*).

Kao što se vidi na prethodnoj slici, u laboratorijskim uslovima, korišćen je generator signala. Signal generator generiše WCDMA signal sa frekvencijom nosioca na 2.14 GHz, a demodulacija je podešena da prihvata WCDMA signal na 2.14 GHz. Frekvencija i vrsta signala su odabrane tako da odgovaraju LTE specifikacijama. Signal WCDMA je korišćen kao *proof of concept* jer u trenutku razvijanja modela OFDM signal nismo imali u Matlab formatu.

B. Odabir ANN modela

Kako bi se uzeo u obzir prethodno pomenuti memorijski efekat, za modelovanje pojačavača korišćena je dinamička neuronska mreža sa kašnjenjem koja ima realne ulazne vrednosti (eng. *Real-Valued Time Delay Neural Network* - RVTDNN). Ustanovljeno je da je ova ANN topologija efikasna u modelovanju nelinearnog PA [4]. Nelinearni efekti praćeni izraženim memorijskim efektima su mnogo izraženiji u odnosu na rad [4], jer se koristi tri puta širi spektar da bi se video potencijal primene ovo metodologije u izrazito nelinearnim širokopojasnim multifrekvencijskim sistemima. Ovde se pod ulazom sa realnim vrednostima podrazumeva kompleksni ulazni signal (širokopojasni signal) koji se sastoji od dve komponente, od kojih jedna predstavlja vrednost realnog dela signala, a druga vrednost imaginarnog dela signala. Na Sl. 4 dat je šematski prikaz RVTDNN topologije sa dva skrivena sloja, sa dubinom memorije p i q. Na Sl. 4, RVTDNN model ima četiri ulaza: dve komponente ulaznog signala (I_{in}, Q_{in}) i dve komponente zakašnjenog izlaznog signala (I_{out}, Q_{out}). Predložena RVTDNN mreža se zasniva na *feedforward* strukturi ANN mreže [11], sa dodatkom četiri linije za kašnjenje (eng. *Tapped Delay Line* - TDL) u ulaznom nivou, na svakom ulazu po jedan TDL.



Sl. 4. Šematski prikaz RVTDNN topologije sa dva skrivena sloja.

Na Sl. 4, p označava dubinu memorije ulaznog signala, a q dubinu memorije izlaznog signala; broj TDL linija za kašnjenje kod izlaznog signala na ulazu mreže jednak je (q-1), jer je prvi zakašnjeni signal prikazan kao direktno povezan na ulazni sloj. Shodno tome, TDL struktura ugrađena u RVTDNN obezbeđuje modelovanje kratkoročnih memorijskih efekata koje pokazuje PA. Što se dugoročnih memorijskih efekata tiče, one su ugrađene u samu topologiju RVTDNN, i to kroz učenje pod nadzorom (eng. *supervised learning*), koje predstavlja jedan od načina obučavanja ANN mreže. Ovakav način modelovanja dugoročne memorije može da pomogne kod praćenja sporih dinamičkih promena nelinearnih karakteristika PA tokom vremena.

Prikazana RVTDNN može biti predstavljena ulaznim vektorom $2(p + q + 1)$, gde p i q predstavljaju dubinu memorije u vidu prethodnih odbiraka ulaznih komponenata (I_{in}, Q_{in}) i izlaznih komponenata (I_{out}, Q_{out}) u datom trenutku. Ulazni vektor u datom trenutku obuhvata realne vrednosti trenutnog i prethodnih odbiraka obe komponente ulaznog i izlaznog signala, i može biti pretstavljen kao:

$$X_{in} = [\ I_{in}(n), I_{in}(n-1), \dots, I_{in}(n-p), \quad (1)$$
$$Q_{in}(n), Q_{in}(n-1), \dots, Q_{in}(n-p),$$
$$I_{out}(n-1), \dots, I_{out}(n-q),$$
$$Q_{out}(n-1), \dots, Q_{out}(n-q)].$$

C. Metrike korišćene u analizi

Prilikom modelovanja pojačavača, pored analize dubine memorije, vršena je analiza i u pogledu broja skrivenih slojeva i broja neurona u skrivenim slojevima. Metrike koje su korišćene prilikom analize su NMSE (*Normalized Mean-Square Error*) i NAMSE (*Normalized Absolute Mean-Square Error*). Naime, NMSE metrika daje dobar uvid u *in-band* odziv, ali ne pokazuje performanse u susednim kanalima, gde je lociran najveći deo nelinearne distorzije koji uzrokuje smetnje u drugim komunikacionim kanalima. NMSE metrika se definiše na sledeći način:

$$NMSE_{dB} = 10\log_{10}\left(\frac{\sum_{n=1}^{K}|y_{meas}(n)-y_{est}(n)|^2}{\sum_{n=1}^{K}|y_{meas}(n)|^2}\right), \quad (1)$$

gde su $y_{meas}(n)$ i $y_{est}(n)$ izmereni i predviđeni (modelovani) izlazni signali, respektivno, K je broj odbiraka izlaznog signala, BW predstavlja normalizovan opseg, a f je normalizovana frekvencija.

NAMSE metika služi za robusniju procenu performansi i definiše se kao:

$$NAMSE_{dB} = 10\log_{10}\left(mean_{f\epsilon[f\ min, f\ max]}\left(\frac{|Y_{meas}(f)-Y_{est}(f)|}{|Y_{meas}(f)|}\right)\right), \quad (2)$$

gde su $Y_{meas}(f)$ i $Y_{est}(f)$ spektralne gustine snage signala na izlazu DUT-a i izlazu modela, respektivno. Frekvencijski opseg $[f\ min, f\ max]$ se može prilagoditi tako da uzima u obzir celokupan frekvencijski opseg, ili samo specifične opsege koji odgovaraju intermodulacionim produktima trećeg i petog reda.

NAMSE razmatra grešku u frekvencijskom domenu između izmerenog i modelovanog spektra. Izbegavanjem integracije, NAMSE predstavlja više mikroskopsku metriku koja daje jednak značaj svim spektralnim regionima, nezavisno od nivoa snage. Prema tome, očekuje se da će ova metrika da da vrlo preciznu kvantifikaciju performansi modela ponašanja.

D. Obučavanje mreže

Tokom obučavanja (treniranja) ANN mreže koristili smo postupak kros-validacije (eng. *cross-validation*). U sklopu ovog postupka postoje dve faze, faza treniranja (eng. *training phase*) i faza testiranja (eng. *test phase*). Treniranje predložene mreže izvrešeno je korišćenjem različitih segmenata izmerenog ulaznog i izlaznog signala, kako bi se obezbedila dobra sposobnost generalizacije ANN modela. Trening skup sastojao se od 9.000 odbiraka, a test skup od 26.000 odbiraka. Broj odabiraka u test skupu je s namerom izabran skoro tri puta veći od onog koji je korišćen tokom treniranja, kako bi se procenila sposobnost generalizacije ANN modela. Sposobnost generalizacije ANN mreže definiše se kao sposobnost mreže da predvidi tačan izlaz za ulazni signal koji se razlikuje od ulaznih signala koji su korišćeni prilikom treninga ANN mreže. Bitno je napomenuti, da su odabirci u trening i test skupovima bili različiti. Test faza ima za cilj proveravanje sposobnosti ANN modela da predvidi izlaz za ulazne signale koji nisu korišćeni prilikom obučavanja mreže; na ovaj način se proverava sposobnost generalizacije ANN modela. Maksimalno broj epoha prilikom treniranja je bio postavljen na 10,000, ali je pri obuci svih razvijenih RVTDNN modela broj epoha bio znatno manji od maksimalnog, odnosno zadate performanse modela su bile postignute sa mnogo manje epoha. Nivo učenja je bio postavljen na 0.1. Ova vrednost izabrana je na osnovu naših

prethodnih istraživanja, jer se pokazalo da veće vrednosti novoa učenja dovode do smanjenja generalizacije mreže.

E. Optimalna ANN struktura

Kao što je već napomenuto, kako bi se odredila optimalna ANN struktura za izabrani PA izvršena je analiza nekoliko ANN parametara, tačnije, optimizacija ANN strukture je vršena u pogledu četiri parametra, broja skrivenih slojeva, broja neurona u skrivenim slojevima, dubine memorije ulaznog signala, i dubine memorije izlaznog signala. Metrike koje su korišćene prilikom odabira optimalnih vrednosti pomenutih četiri parametara, su gore definisane metrike, NMSE i NAMSE. Prilikom odabira optimalnog modela, pored ovih metrika upoređivane su i sledeće karakteristike: amplitudska karakteristika, fazna karakteristika, i *Error Spectrum* karakteristika, koje se uobičajno koriste prilikom procene podobnosti ANN modela pojačavača.

Prilikom modelovanja razvijeno je više RVTDNN modela, koji se mogu svrstati u dve kategorije: RVTDNN modeli sa jednim skrivenim slojem, i RVTDNN modeli sa dva skrivena sloja. Broj skivenih slojeva nije povećavan preko 2 jer shodno UAT teoremi, ANN sa jednim skrivenim slojem i promenljivim, monotono rastućim, kontinualnim aktivacionim funkcijama može da aproksimira bilo koju nelinearnu funkciju sa željenom verovatnoćom greške, tako da smo povećanje broja skrivenih slojeva preko 2 smatrali neoptimalnim. Takođe, srodne studije pokazuju da je u najvećem broju slučajeva za modelovanje pojačavača potrebno realizovati ANN mrežu sa maksimalno dva skrivena sloja. Prema rezultatima, mreža sa dva skrivena sloja je u našem slučaju dala bolje rezultate, tako da je RVTDNN struktura sa dva skrivena sloja uzeta kao optimalna. U pogledu broja neurona u skivenim slojevima, najbolje performanse su dobijene kada je broj neurona u prvom skrivenom sloju bio 12, a u drugom 15, kao što je prikazano u Tabeli I.

Analiza je pokazala da je optimalna dubina memorije ulaznog signala jednaka nuli. Odnosno, dovođenje zakasnelih ulaznih signala zajedno sa trenutnim ulaznim signalom nije rezultiralo poboljšanjem performansi ANN modela.

Što se tiče dubine memorije izlaznog signala, rezultati su pokazali da je optimalno rešenje dubina memorije 3, odnosno dovođenjem tri zakasnela izlazna signala na ulaz mreže dobijeni su najbolji rezultati u pogledu NMSE i NAMSE performansi, i AM/AM, AM/PM i *Error Spectrum* karakteristika. Rezultati za različite dubine memorije izlaznog signala prikazani su u Tabeli II.

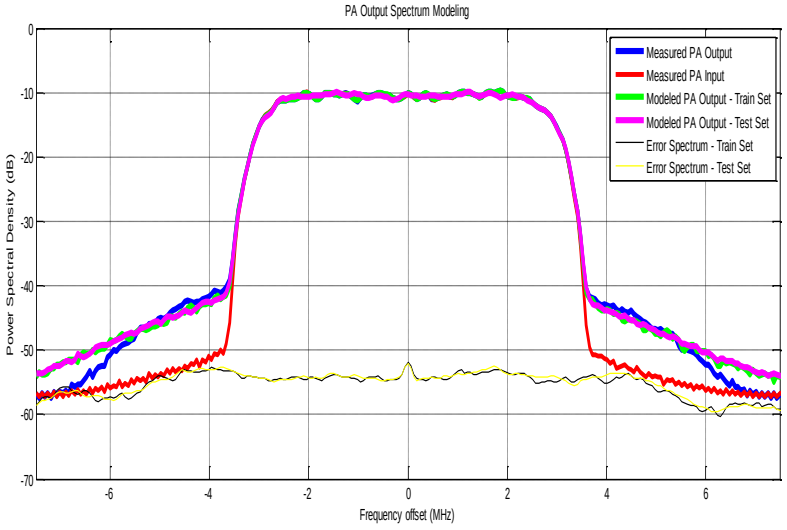
TABELA I
BROJ NEURONA U SKRIVENIM SLOJEVIMA

Broj neurona	*NMSE Train* (dB)	*NMSE Test* (dB)	*NAMSE Train* (dB)	*NAMSE Test* (dB)
I_HL=3, II_HL=3	-34.7318	-34.6660	-20.0209	-19.6848
I_HL=5, II_HL=3	-33.8056	-33.9593	-20.0906	20.1189
I_HL=7, II_HL=3	-37.7937	-37.7562	-21.7221	-21.3805
I_HL=5, II_HL=12	-38.1693	-38.1740	-22.0861	-21.9001
I_HL=12, II_HL=15	-40.5347	-40.3897	-22.6781	-22.2835

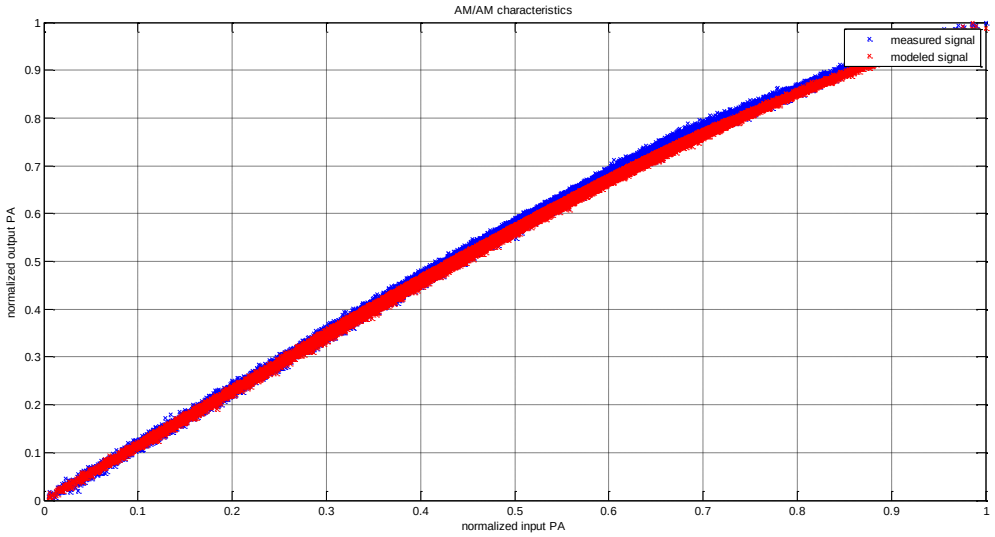
TABELA II
DUBINA MEMERIJE IZLAZNOG SIGNALA

Dubina memorije	*NMSE Train* (dB)	*NMSE Test* (dB)	*NAMSE Train* (dB)	*NAMSE Test* (dB)
$q = 0$	-37.4279	-37.4267	-20.5748	-20.5171
$q = 2$	-39.9849	-39.8766	-22.5726	-22.2998
$q = 3$	-40.1665	-40.0677	-22.4296	-22.2632
$q = 5$	-38.6017	-38.4715	-22.0837	-21.7430

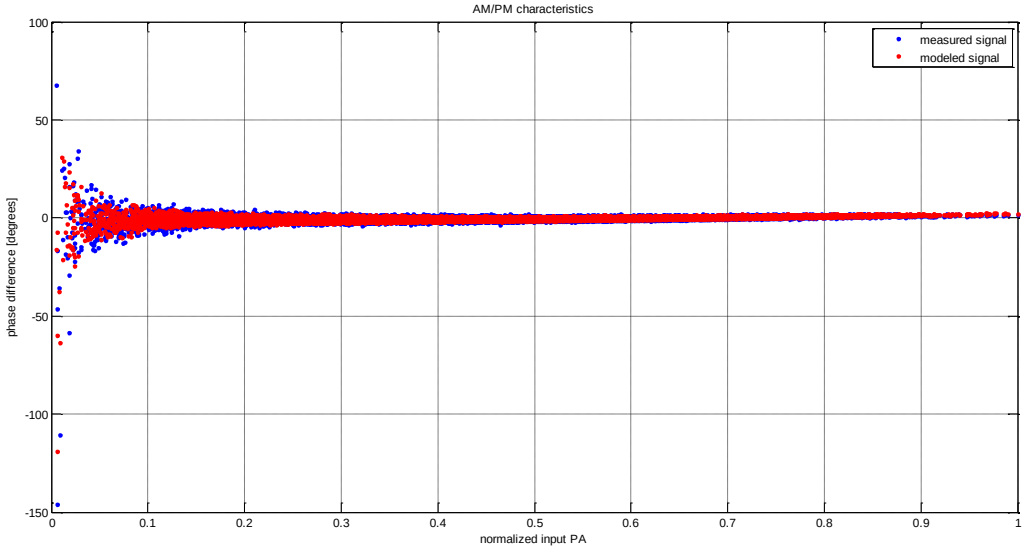
Uporedni izgled spektra signala za mereni i modelovani izlaz za trening i test skup za optimalni RVTDNN model prikazan je na Sl. 5. Na Sl. 6-9 date su AM/AM, AM/PM i *Error Spectrum* (razlika između izmerene i modelovane spektralne karakteristike) karakteristike.



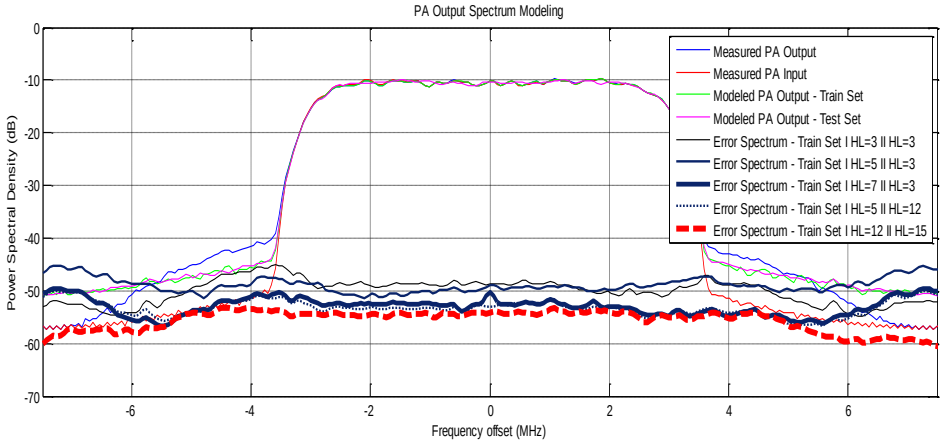
Sl. 5. Izgled spektra signala na izlazu iz RVTDNN mreže za q=3 (izmereni spektri su nornalizovani).



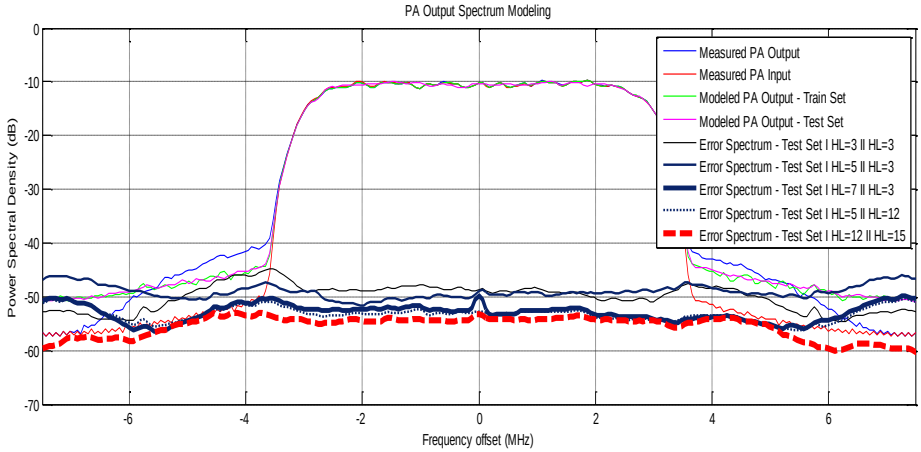
Sl. 6. AM/AM karakteristika za q=3.



Sl. 7. AM/PM karakteristika za q=3.



Sl. 8. Normalizovani spektri signala i *Error Spectrum* karakteristika za trening skup za različite brojeve neurona u skrivenim slojevima.



(b)

Sl. 9. Normalizovani spektri signala i *Error Spectrum* karakteristika za test skup za različite brojeve neurona u skrivenim slojevima.

Kao što se na prethodnim slikama može videti, razvijen RVTDNN model ima dobre performanse po svim razmatranim kriterijumina.

IV. Zaključak

U ovom radu prikazan je postupak modelovanja pojačavača snage CFH-2163-P3 primenom veštačkih neuronskih mreža i sa signalom koji je tri puta širi u odnosu na prethodna istraživanja. Za modelovanje pojačavača korišćena je RVTDNN mreža sa dva skrivena sloja i sigmoidalnom prenosnom funkcijom. Razvijeni model je optimizovan po broju neurona u skrivenim slojevima i dubini memorije ulaznog i izlaznog signala; optimlan broj neurona u skrivenim slojevima je bio 12 i 15, dubina memorije ulaznog signal je jednaka nuli, a dubina memorije izlaznog signal je jednaka 3. Performanse razvijenog modela u pogledu NMSE i NAMSE su ispod -40 dB i -20 dB, respektivno, što predstavlja dobar rezultat. Poklapanje AM/AM, AM/PM i spektara modelovanog i merenog signala je dobro, što potvrđuje podobnost razvijenog modela pojačavača.

U okviru našeg daljeg rada biće razvijem inverzni model za pojačavač snage CFH-2163-P3 primenom veštačkih neuronskih mreža, zarad razvoja DPD modela za dati izrazito nelinearni pojačavač i izrazito širokopojasne sisteme.

Abstract

In this paper, a power amplifier intended for LTE systems is modeled using artificial neural networks. The Real-Valued Time Delay Neural Network – RVTDNN is used in modeling. The RVTDNN model is optimized regarding the number of hidden layers, the number of neurons in the hidden layers, memory depth of the input signal, and memory depth of the output signal. The measures used in model evaluations are NMSE (Normalized Mean-Square Error) and NAMSE (Normalized Absolute Mean-Square Error). The optimized RVTDNN model has 12 and 15 neurons in the first and second hidden layers, respectively, and memory depth of the input and output signals are equal to 0 and 3, respectively. The AM/AM, AM/PM and error spectrum characteristics of the optimized model show excellent agreement with the measured characteristics on the test dataset, which differs from the training dataset.

Modeling of PA for LTE Systems Based on RVTDNN Neural Networks

Influence of Mechanical Activation on Electrical Properties of Ceramic Materials in VHF Band

Nina Obradović and Antonije Đorđević

***Abstract*—Mechanical activation is commonly used as a pre-sintering process in order to enhance the reactivity of materials, reduce the particle size, increase diffusion rates, accelerate the reaction, and lower the sintering temperature. The mechanical activation can affect the final electrical and mechanical characteristics. In this paper we consider the influence of the mechanical activation on the permittivity and the loss tangent. We outline methods for evaluation of these parameters, with emphasis on our coaxial-chamber technique for measurements in the VHF band.**

***Index Terms*—Ceramic materials; mechanical activation; sintering; electrical properties; numerical modeling; measurements of dielectric parameters.**

I. Introduction

Ceramic materials are solid materials obtained by sintering of appropriate mixtures of powders. "Ceramic" is derived from the Greek word "keramos", which means potter's clay or pottery [1]. Ceramic materials have many technical applications. Advanced materials, such as alumina, aluminum nitride, borides, zirconia, silicon carbide, silicon nitride, silicon- and titania-based materials offer a high-performance and economic alternative to conventional materials, such as glass, metals, and plastics.

The sintering is one of the most important phases in the production process of ceramic materials. Specific predetermined properties of ceramics are required along with cost-effectiveness of the manufacturing process [2]. In order to obtain materials with the desired properties during the sintering process, one should simultaneously take into account several factors: the size, shape, and structure of the particles, particle-size distribution, particle packing, the purity of the starting mixtures, the density of compacts (samples obtained after consolidation, prior to the sintering process), the appropriate sintering regime (temperature and sintering time, heating/cooling rate), the atmosphere in which the process is performed, the existence of impurities and/or additives, etc. It has been empirically determined that a decrease in the particle size of reactants leads to an increase of the isothermal process constant rate without changes in the activation energy of the process [3]. The increase of the specific surface area that is induced by the mechanical activation plays an important role. Extremely small particles require application of a higher pressure during the consolidation process. Due to the non-homogeneous package and gas retention, samples get stratified and the sintering leads to formation of cracks. The presence of large particles causes an excessive grain growth during the sintering. By adjusting the conditions of the pre-treatment, we can prepare the starting powder with the predefined optimal particle-size distribution.

Basically, the sintering processes can be divided into two types: the solid-state sintering and the liquid-phase sintering. The solid-state sintering occurs when the powder compact is densified wholly in the solid state at the sintering temperature. The liquid-phase sintering occurs when a liquid phase is present in the powder compact during the sintering [4].

Ceramic materials are used in electrical engineering as insulators, chip carriers, dielectrics for capacitors, in fabrication of multilayer ceramic (MLC) devices, in particular LTCC (low-temperature co-fired ceramics), for various optical devices, etc. Various properties of these materials are important, depending on the application. The relevant electromagnetic properties of the sintered materials include dielectric properties (permittivity, losses, and breakdown), insulating/conductive properties, magnetic properties (permeability, losses, nonlinearities, and Curie temperature), and possible piezoelectric properties. The thermal conductivity is important for heat transfer in semiconductor devices. Adherence of metals and semiconductors, including dilatation and compatibility with adhered materials, is essential for fabrication processes, etc.

In this paper, we consider only nonmagnetic materials and are focused on the electrical properties of the ceramics. We assume that the material is linear. We consider the complex relative permittivity and quantities related to it (the loss tangent and the conductivity), predominantly in the VHF (Very High Frequency) band, which extends from 30 MHz to 300 MHz. Fig. 1 presents the position of the VHF band in the spectrum. The data include free-space wavelength (λ), the frequency (f), the energy of a quantum, and the designation.

We present our measurement technique for the relative permittivity of ceramic samples in the VHF band, which can also be applied in higher frequency bands, in the microwave region, up to around 10 GHz.

This paper is organized as follows. In Section II, we briefly present methods of mechanical activation and the sintering process. In Section III, the complex permittivity is introduced. In Section IV, we provide a description of our measurement technique. In section V, we give examples of measured permittivities of ceramic materials. Finally, Section VI concludes the paper.

II. Mechanical Activation and Sintering

The mechanical activation represents a complex physico-chemical process, which leads to an increase of chemical activity and potential energy of the treated material. Such a process can cause changes in the specific surface area and internal energy within the system. The free energy of the system is also increased [5]. During the mechanical activation of an inorganic material, attrition of the material takes place and reduces the crystallite size, which further leads to deformation or changes in the crystal structure, accompanied by generation of defects [6–9]. Grinding of the material is carried out by successive fracturing of particles (Fig. 2). The method of obtaining the finest powder is called dispersion milling [10]. Equipment used for grinding is a mill. There are several types of high-energy mills: attrition mill, vibro mill, horizontal ball mill, and planetary mill.

In terms of the grinding process, the influence of the mechanical forces on the material leads to formation of elastic and plastic deformations. During the elastic collision, the whole energy of the system remains unchained, as well as the material structure. During the plastic collision, the energy is partially transformed into the energy of deformation. Physico-chemical properties of materials are changed by these deformations [11]. The reaction capability of solid materials increases as a direct result of structural changes within the material by applying the method of mechanical activation. Changes of the structure of the crystal lattice are reflected trough the generation of point defects (vacancies, interstitial atoms, and impurity atoms), line defects (atom aggregations on the crystal surface), volume defects (pores and impurities), and electron defects (electrons and holes) [12, 13]. The occurrence of defects during mechanical activation represents the general tendency of crystals to transform the mechanical energy into the energy of the crystal lattice defects. During the mechanical treatment, the condition of the treated system is constantly changing, from the stage of the initial powder, where particles are poorly connected, to the stage of a heterogeneous system, where larger agglomerates form out of smaller powder particles with clearly defined boundaries.

Grinding of the material is carried out by successive fracturing of the powder particles in the mills. The mechanical activation leads to fragmentation, decrease of the particle size, and change of the free surface and the physico-chemical properties of crushed material. It is performed in order to improve the reactivity of the system or for the purpose of its amorphization. This treatment increases the reactivity of the material and lowers the temperature and time of sintering [15, 16].

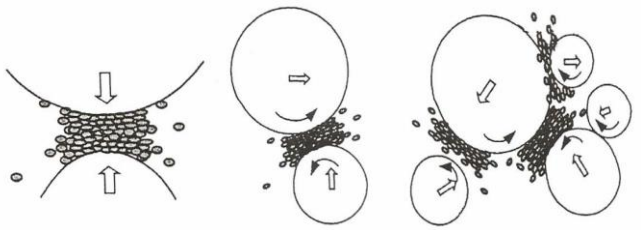

Fig. 2. Collisions that occur during milling in a high-energy planetary ball mill [14].

The method of mechanical activation has a variety of advantages compared to other methods of powder preparation, such as relatively cheap equipment (mills), inexpensive production, possible appliance to all classes of materials, and obtaining large quantities of material for further investigation. The main disadvantage of this method is the formation of agglomerates in the powder after milling. The powder agglomeration can be controlled and avoided by choosing adequate synthesis parameters. Firstly, the time of activation. According to the literature data, authors apply times in the range of two to five minutes, adequate for mixing and homogenization of powders [17, 18], up to dozens of hours, in cases of very hard materials or difficult and complex reactions occurring in the system [19–21]. Secondly, the ball-to-powder mass ratio. Authors choose the ball-to-powder mass ratio depending on how much energy they wish system to get during milling. Authors usually choose 20:1 or 40:1 ball-to-powder mass ratio, in order to obtain great energy transfer and easier and faster mechanochemical reaction [22–24]. Thirdly, selection of the material that the mill is made of. There is a variety of materials in usage, such as ZrO_2, WC-Co or hardened steel [25–27]. There is a possibility that during prolonged activation some particles from balls and vessels drop off and incorporate into the powder particles. Hence, prolonged milling time is not very suitable or milling equipment needs to be new and unused. Finally, the choice of the milling medium is also very important. It could be dry milling, conducted in air, or wet milling, e.g., in ethanol [28, 29]. Usually, milling is performed in air, but if the objective is to avoid the agglomerates, wet milling can be performed. To protect the powders from oxidation, the milling can take place in an inert atmosphere (at atmospheric pressure), either Ar or N_2 [30]. The method of mechanical activation attracts great attention due to its simplicity and because many parameters can be changed and optimized, which makes the work in a laboratory interesting, challenging, and novel each time.

G. V. Samsonov gave the most complete definition of the sintering process: “Sintering is a set of complex and interconnected mass transport processes that occur between the particles and within the particles of dispersed system during its consolidation” [31]. The necessary energy needs to be transferred into the system, so the sintering process can take place. It can be thermal (heating), mechanical (sintering under high pressure), or of some other form of energy (e.g., microwave sintering). The free energy of the system, which is in the non-equilibrium state, represents a driving force for the sintering process. The non-equilibrium state is a consequence of a developed specific surface area of powder particles and structural defects within them.

The sintering process of real materials can be conditionally divided into three stages [15], as illustrated in Fig. 3:

(1) In the initial stage, a contact is made between individual particles, but particles retain their structural individuality. During this stage, the density changes slightly and at the end of this stage, its value is 60–75 % of the theoretical density. At this sintering stage, the establishment of a better contact between particles and neck growth are a consequence of simultaneous acting of several mechanisms (viscous flow, surface diffusion, and volume diffusion). Open porosity is dominant, with pores of irregular shape and fracture trough grains.

(2) In the middle stage, particles accrue to one another. This leads to fast growth of contact necks, space between particles loses its shape, and particles lose their individuality. Pores get a more regular shape; their closure begins along with grain growth. Densification is most intensive in this intermediate phase. Fractures between grains and fractures trough grains are present at this sintering stage.

(3) The final stage is characterized by further formation of closed pores and grain growth. Due to shrinkage, open pores are too narrow to be stable and they are transformed into closed pores; then sintering enters the final stage. Density values are 90–93 % of the theoretical density. The final sintering stage is characterized by elimination of closed pores and approaching the theoretical density. The volume diffusion and diffusion along grain boundaries are dominant in the middle and final sintering stages. There are no sharp boundaries between these three stages of sintering.

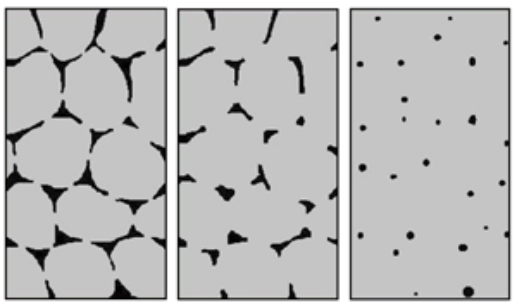

Fig. 3. The three stages of solid-state sintering [32].

In practice, technological factors have a great influence on the sintering process. Most important are: particle shape and size within the initial powder, the purity of the starting powders, the density of compacts (compaction pressure), sintering temperature, sintering regime, sintering atmosphere, etc.

There are a number of equations describing the process of sintering in the literature, which certainly indicate the great complexity of the process. Each of these equations refers to either the individual stages of sintering, or to certain mechanisms. Therefore, the basic questions concerning the kinetics and mechanisms are solved by usage of models (two-sphere model, sphere and flat plain model, etc.). A two-sphere model is most commonly used (Fig. 4). An increase of the contact surface may be caused by several mechanisms. Different types of diffusion in a solid state allow transport of the mass:

(1) The viscous flow consists of a deformation of the crystal structure under the influence of the surface tension. The mass transport occurs owing to the directional movement of atoms from the volume of the particles to the contact neck. During this process, the work that is carried out by the forces of the surface tension is equated with the work of forces of internal friction. An increase of the contact neck occurs along with reducing the distance between the particles [33].

(2) The surface diffusion is the most general mechanism which occurs during the sintering of crystalline materials. The spontaneous transport of atoms on the particle surface is dominant. During the growth of the contact neck, the distance between particle centers remains the same, without an increase in density of the material. The surface diffusion is the most common mechanism for lower temperatures of sintering and small particles.

(3) The volume diffusion is a mechanism where the mass transfer occurs by the diffusion flow from the particle surface to the contact neck. During this type of sintering, the vacancy concentration has a great impact on the diffusion velocity. This is crucial for materials with additives, where vacancies depend directly on the concentration of dopants. In this way, the concentration of the added material has an impact on the diffusion coefficient, and consequently on the mass transfer.

(4) The evaporation-condensation is a mechanism where the mass transfer occurs due to the difference of the vapor pressure of the solid phase in various parts of the system. Owing to the existence of a higher vapor pressure of the solid phase on the convex surface, and a lower vapor pressure of the solid phase on the concave surface, the material evaporates from the convex surface and via the gas phase gets transferred to the concave surface, where it condenses. The distance between the particles does not change; hence, the evaporation-condensation mechanism does not contribute to the densification of the system.

(5) The diffusion along grain boundaries is a mechanism in which the mass transport occurs from the border area between the particles to the surface of the contact neck, by diffusion along the edge. The contribution of this mechanism to the total mass transport is not large because the extent of the grain boundaries is limited. The diffusion of substances from the grain border area to the surface of the contact neck ensures particle approaching, and produces the effect of a compact shrinkage during sintering. It also causes a change in the shape and size of pores, reducing the porosity.

One of the most important issues that need to be understood in the context of studying the process of

sintering is the way of pore elimination.

Based on experimental data, it was concluded that materials which contain large pores are sintered slower, while the smaller pores can be eliminated from the system during heating at significantly lower temperatures. The system will enter the final sintering stage when the temperature is sufficient to ensure an increase in the grain size by that level where the critical pore size reaches the size of the largest pore in the system. When the system reaches the phase where all pores are smaller than the critical pore size, it may result in a full densification of the ceramic material. That explains the poor sinterability of agglomerated powders [34].

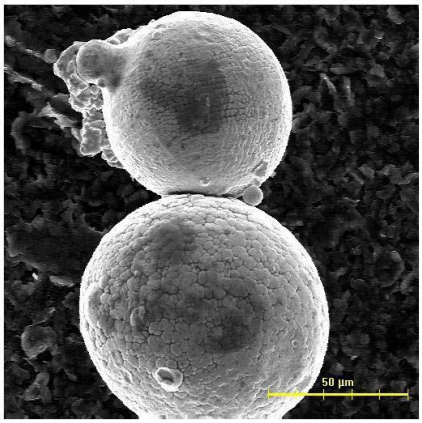

Fig. 4. An accretion of two real particles obtained by scanning electron microscopy [14].

Agglomerates are sets of small related particles that form large pores in the compact during the sintering process. As the process progresses, pores between agglomerates become larger, while pores within the agglomerates are reduced. The agglomeration or other processes, whose action makes a different pore size, suppress the sintering as long as there are two types of pores in the structure—larger ones between the agglomerates and smaller ones within the agglomerates. As the process develops, the large pores grow, while the smaller ones decrease. In the case of samples with a high initial density (the density after the compaction process, prior to the sintering), the pores between the agglomerates are reduced, and the negative effect of the existence of the two types of pores is decreased [35, 36].

Various techniques have been developed to obtain dense ceramics with a desired microstructure and phase composition. In general, these methods involve a combination of a heating regime and applied pressure. Heating regimes can be simple, as in the isothermal sintering, or can have a complex temperature-time relationship, as in the rate-controlled sintering, while the pressure may be applied either uniaxally, with or without a die, or by a surrounding gas [37]. The control of the sintering atmosphere is also important, and a precise control of oxygen or nitrogen partial pressures as a function of temperature may in some cases be beneficial or essential. Insoluble gas trapped in closed pores may obstruct the final stages of densification; hence, a change in the sintering atmosphere or a vacuum sintering is required. There are various heating regimes, such as: isothermal sintering, constant-heating-rate sintering, multi-stage sintering, rate-controlled sintering, microwave sintering, spark-plasma sintering, hot pressing, and hot-isostatic pressing.

Before we can chose the appropriate pre-sintering treatment and adjust its parameters, it is very important to have in mind that the resulting structure of the obtained compound is a direct result of structural changes at all hierarchical levels, caused by the applied treatment. It is possible to influence the development of the microstructure and to achieve the optimum and desired properties of the final material by a proper choice of the pre-sintering treatment and the type of the sintering process.

III. Complex Permittivity

In this paper, we consider dielectric properties of ceramic materials. These properties can be described by various parameters, such as polarizability, permittivity, dissipation factor (loss tangent), etc. In engineering applications, the complex relative permittivity is often used to characterize a dielectric material.

From the engineering standpoint, we live in the time domain: various physical quantities are functions of time, such as voltages, currents, electric fields, etc. In reality, the time dependence is known only for the past. However, in order to enable a mathematical description, we often assume that the time dependence is given analytically, by a certain mathematical function.

Furthermore, our world is causal: the response to a given excitation cannot occur before the excitation starts. If we consider electromagnetic waves, we even have a delay due to the propagation, so that the response is delayed after the excitation. The fastest known propagation is in a vacuum, where the velocity is $c_0 = 2{,}99792458 \cdot 10^8$ m/s .

In the engineering analysis, time-harmonic (sinusoidal) functions are often used to describe various periodic physical quantities [38]. Such functions also occur in the Fourier analysis. For example, a time-harmonic current, shown in Fig. 5, is given in the standard (canonical) form as

$$i(t) = I_\mathrm{m} \cos(\omega t + \psi), \qquad (1)$$

where t is the time ($-\infty < t < +\infty$), I_m is the amplitude ($I_\mathrm{m} \geq 0$), $\omega = 2\pi f$ is the angular frequency and f is the frequency, whereas ψ is the initial phase (usually reduced to the interval $-\pi < \psi \leq \pi$). The period (T) and the frequency are related as $fT = 1$.

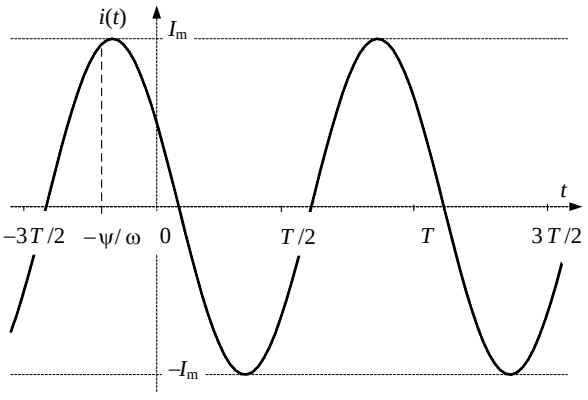

Fig. 5. Time-harmonic current.

Time-harmonic functions cannot occur in reality, because they span infinite time ($-\infty < t < +\infty$), but they can

conveniently describe various quantities in electrical engineering. In particular, if we consider a linear system and apply a time-harmonic excitation, the response will, in most practical cases, also be a time-harmonic function.

However, there are several difficulties in the analysis of such systems. The main one occurs when evaluating a sum or a difference of two time-harmonic quantities. The result is also a time-harmonic quantity of the same frequency, but expressions for the amplitude and phase of the result are rather cumbersome.

This difficulty is bypassed by introducing phasor (complex) representatives of the time-domain quantities and performing the analysis in the frequency (complex) domain. For example, the complex representative $\underline{I}$ of the time-domain current (1) is introduced by:

$$i(t) = \mathrm{Re}\left\{ \underline{I}\sqrt{2}\, \mathrm{e}^{-\mathrm{j}\omega t} \right\}, \tag{2}$$

where Re denotes the real part, $\mathrm{e} = 2.718281\ldots$ is the base of the natural logarithm, and $\mathrm{j} = \sqrt{-1}$ is the imaginary unit. In the exponential form, $\underline{I} = I\mathrm{e}^{\mathrm{j}\psi}$. The modulus (magnitude) of $\underline{I}$ is the root-mean-square (rms) value of $i(t)$, $I = |\underline{I}| = \frac{I_\mathrm{m}}{\sqrt{2}}$, and the argument (angle) of $\underline{I}$ is the initial phase of $i(t)$. Note that (2) is related to the Fourier and Laplace transforms.

Once we have phasors, addition and subtraction in the time domain is replaced by addition and subtraction of phasors, which is easily performed because we merely have to add or subtract complex numbers.

Additionally, the phasors facilitate solutions of linear differential equations: the differentiation in the time domain is mapped into the phasor domain as a multiplication by $\mathrm{j}\omega$. Hence, a linear differential equation in the time domain is mapped into an algebraic equation in the complex domain.

Equation (2) is valid for scalar quantities. A similar mapping can be applied to time-harmonic vectors as well [39]. Let us first define a time-harmonic vector, e.g., the electric-field vector, $\mathbf{E}(t)$. In Cartesian coordinates,

$$\mathbf{E}(t) = \mathbf{u}_x E_x(t) + \mathbf{u}_y E_y(t) + \mathbf{u}_z E_z(t), \tag{3}$$

where $\mathbf{u}_x$, $\mathbf{u}_y$, and $\mathbf{u}_z$ are the unit vectors of the Cartesian system, and

$$E_x(t) = E_x\sqrt{2}\cos(\omega t + \theta_x), \tag{4}$$

$$E_y(t) = E_y\sqrt{2}\cos(\omega t + \theta_y), \tag{5}$$

$$E_z(t) = E_z\sqrt{2}\cos(\omega t + \theta_z) \tag{6}$$

are time-harmonic functions of the same angular frequency ω, but can have different rms values (E_x, E_y, E_z) and initial phases ($\theta_x, \theta_y, \theta_z$). The complex representative of $\mathbf{E}(t)$ is now defined as

$$\underline{\mathbf{E}} = \mathbf{u}_x \underline{E}_x + \mathbf{u}_y \underline{E}_y + \mathbf{u}_z \underline{E}_z, \tag{7}$$

where $\underline{E}_x$, $\underline{E}_y$, $\underline{E}_z$ are the complex representatives of the components $E_x(t)$, $E_y(t)$, and $E_z(t)$, defined in accordance with (2).

Note that the complex domain is only a mathematically introduced "parallel world". Phasors (complex representatives) cannot be physically related to time-domain quantities.

The state in a polarized dielectric is macroscopically described by the polarization vector, **P** [40]. In the analysis of electromagnetic fields, in order to avoid dealing with the polarization vector, the electric displacement vector is introduced as defined by:

$$\mathbf{D} = \varepsilon_0 \mathbf{E} + \mathbf{P}, \tag{8}$$

where:

$$\varepsilon_0 = \frac{1}{\mu_0 c_0^2} = \frac{25\cdot 10^5}{299792458^2\,\pi}\ \mathrm{F/m} \tag{9}$$

is the permittivity (dielectric constant) of a vacuum. If the dielectric is linear, then the polarization vector is linearly proportional to the electric field (**E**) and, consequently, the vector **D** is also linearly proportional to **E**:

$$\mathbf{D} = \varepsilon \mathbf{E}, \tag{10}$$

where ε is the absolute permittivity (dielectric constant). Further, we can set $\varepsilon = \varepsilon_\mathrm{r}\varepsilon_0$, where ε_r is the relative permittivity (relative dielectric constant) of the material. Generally, a linear dielectric may be anisotropic (e.g., quartz), when the vectors **D** and **E** are not collinear, and ε_r is a tensor. In this paper, however, we assume the dielectric to be isotropic, so that **D** and **E** are collinear, and ε_r is a scalar. Note that $|\mathbf{D}| = |\varepsilon||\mathbf{E}|$. For a vacuum, $\varepsilon_\mathrm{r} = 1$. For static fields in linear, isotropic dielectrics, $\varepsilon_\mathrm{r} > 1$.

If the dielectric is located in a time-varying electric field $\mathbf{E}(t)$, the polarization vector is a function of time, $\mathbf{P}(t)$. Hence, the displacement vector is also a function of time, $\mathbf{D}(t) = \varepsilon_0\mathbf{E}(t) + \mathbf{P}(t)$. As a particular case, in the time-harmonic regime, all three vectors are time-harmonic quantities. However, in the general case, they are not in phase. If we switch to the complex domain, we can write

$$\underline{\mathbf{D}} = \underline{\varepsilon}\,\underline{\mathbf{E}}, \tag{11}$$

where $\underline{\varepsilon} = \underline{\varepsilon}_\mathrm{r}\varepsilon_0$ is the complex absolute permittivity and $\underline{\varepsilon}_\mathrm{r}$ is the complex relative permittivity.

The complex relative permittivity can be written as:

$$\underline{\varepsilon}_\mathrm{r} = |\underline{\varepsilon}_\mathrm{r}|\,\mathrm{e}^{-\mathrm{j}\delta} = \varepsilon_\mathrm{r}' - \mathrm{j}\,\varepsilon_\mathrm{r}'' = \varepsilon_\mathrm{r}'(1 - \mathrm{j}\tan\delta), \tag{12}$$

where $|\underline{\varepsilon}_\mathrm{r}|$ is the modulus, $-\delta$ is the argument, ε_r' is the real part, $-\varepsilon_\mathrm{r}''$ is the imaginary part, and $\tan\delta = \varepsilon_\mathrm{r}''/\varepsilon_\mathrm{r}'$ is the loss tangent. The minus sign is introduced because the vector **D** lags behind **E**; the argument of $\underline{\varepsilon}_\mathrm{r}$ is negative, but $\delta > 0$. Obviously, $-\delta$ is the phase difference between **D** and **E**. Further, $|\underline{\mathbf{D}}| = |\underline{\varepsilon}_\mathrm{r}|\,\varepsilon_0\,|\underline{\mathbf{E}}|$ so that $|\underline{\varepsilon}_\mathrm{r}|$ plays a role similar to ε_r in a static field.

Since $\mathbf{D}(t)$ and $\mathbf{E}(t)$ are collinear, we can introduce an axis collinear with these two vectors and consider the projections $D(t)$ and $E(t)$ on this axis. These projections are time-harmonic quantities. We consider the plot shown in Fig. 6, where the abscissa is $E(t)$ and the ordinate is $D(t)$. If $D(t)$ and $E(t)$ are in phase, the point in this plane periodically moves along a straight line (the red dashed line in Fig. 6). If they are not in phase, the point moves along an

ellipse in the counter-clockwise direction, creating a hysteresis loop (Rayleigh loop). Such a loop indicates that the dielectric is lossy. The volume density of the energy loss during one cycle is proportional to the surface area bounded by the ellipse, i.e.,

$$\frac{\mathrm{d}w_\mathrm{h}}{\mathrm{d}v} = \varepsilon_\mathrm{r}''\varepsilon_0 |\underline{\mathbf{E}}|^2 = \varepsilon_\mathrm{r}'\varepsilon_0 |\underline{\mathbf{E}}|^2 \tan\delta, \qquad (13)$$

where $|\underline{\mathbf{E}}|$ is the rms of the electric field. Obviously, the larger is $\tan\delta$, the larger are the losses. Hence, $\tan\delta$ is referred to as the dissipation factor.

Note that in our model $-\varepsilon_\mathrm{r}''$ describes all losses in the dielectric: both polarization and ohmic. If needed, the losses may be described by the equivalent conductivity of the medium (σ) and $-\mathrm{j}\varepsilon_\mathrm{r}''$ replaced in (12) by $-\mathrm{j}\dfrac{\sigma}{\omega\varepsilon_0}$.

For high-quality (low-loss) dielectrics, δ is small, $\tan\delta \ll 1$, and $\varepsilon_\mathrm{r}' \approx |\underline{\varepsilon}_\mathrm{r}|$. What can be considered as a low-loss dielectric, depends on applications. For example, in microwave engineering, for frequencies about 1 GHz, $\tan\delta$ of the order of 0.001 can usually considered to be low.

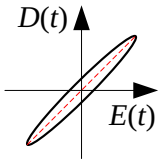

Fig. 6. Hysteresis loop.

The real and the imaginary parts of the complex permittivity are functions of frequency. Due to the causality conditions [41], these functions must satisfy the Hilbert transform (or, equivalently, the Kramers-Kronig relations). Hence, under certain conditions and limitations, if we know ε_r', we can reconstruct $-\varepsilon_\mathrm{r}''$, and vice versa. An important consequence of these relations is that if ε_r' changes with frequency, $-\varepsilon_\mathrm{r}''$ must be nonzero, or, practically speaking, the material must be lossy.

If we need to extract the function $\underline{\varepsilon}_\mathrm{r}(f)$ from measured data, it is convenient to approximate it by an analytic function of the complex frequency $\underline{s}$ ($\underline{s} = \mathrm{j}\omega$ on the imaginary axis of the complex plane), as done, for example, in [42] for FR-4, a material that has an almost constant loss tangent in a very broad frequency range.

IV. Measurement Techniques

Various methods and equipment can be used for measurement of the dielectric parameters [43], depending on the frequency range, aggregate state of samples, shape and size of available samples, etc.

For lower frequencies, up to about 100 MHz, the most commonly used method is based on inserting the material sample between two parallel electrodes, thus forming a parallel-plate capacitor. The capacitance is measured and the dielectric parameters are identified from the result. This technique is simple and convenient for solid samples in many cases. However, for barium titanate, magnesium titanate, and similar high-permittivity materials, air gaps between the sample and the electrodes are formed, which reduce the accuracy. Also, the measurement structure cannot be assumed to be quasistatic already at about 100 MHz. At higher frequencies, internal resonances may occur and jeopardize the measurements.

As the frequency increases, the parallel-plate capacitor has a strong electromagnetic coupling with the environment and it must be shielded. However, the shield creates a resonant cavity, which further aggravates the measurements. In order to push these resonances towards higher frequencies, the size of the cavity should be small.

Another problem with the parallel-plate structure is that it requires samples of an appropriate shape and size. For example, commercially available meters (such as Agilent E4991A meter with Agilent 16451B probe) require a large sample diameter (at least 15 mm), whereas our samples of ceramic materials are much smaller (often up to around 8 mm in diameter). Examples are pill-shaped sintered samples [44], which practically cannot be machined or otherwise adapted to the measurement system.

The parallel-plate capacitor measurement technique is convenient for liquid dielectrics. The main limitation is the relatively low upper frequency limit.

For frequencies above about 1 GHz, open coaxial lines can be used to characterize various materials [45]. This method is convenient because it usually does not require special forming of the sample. However, in order to provide accurate measurements, the sample should be big enough and it tightly positioned on the coaxial-line opening.

It is also possible to characterize a material by placing a sample between two antennas and measure the transfer between the antennas [46]. However, relatively large samples are required (e.g., in the form of a large sheet). Similar techniques exist for measurements in coaxial and waveguide systems [47], but they usually require that the samples have an appropriate shape and dimensions.

Dielectric substrates used in microwave engineering can be characterized by various resonant methods [48]. However, these are narrowband techniques. In order to provide data for a wide frequency band, other techniques can be used, such as manufacturing and measuring various transmission lines [42], which also require a special shape of the dielectric or metallization.

In [49], a method is described that was designed specifically for measurements of samples of ceramic materials that have a cylindrical shape (i.e., a pill-shape) and whose dimensions correspond to the majority of our samples. We have developed a small coaxial chamber, which is, naturally, shielded from the environment. We measure the reflection coefficient of the chamber using a network analyzer and then apply numerical techniques to extract the complex relative permittivity of the sample. However, this chamber requires that the bases of the cylinder are metallized. This can be done using silver-based conductive ink, which does not adhere well to ceramic materials and is messy for application.

We have further improved the measurement method by machining a new coaxial chamber (Fig. 7) and developing the corresponding software for measurements at frequencies in the VHF band [50]. In the meantime, we have developed

new numerical models that enable us to perform measurements up to around 10 GHz. We briefly describe this method in the following paragraphs.

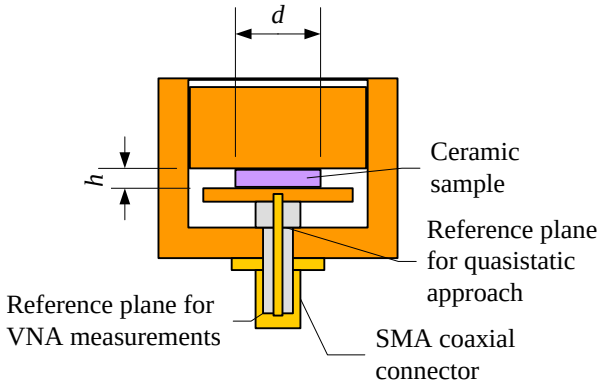

Fig. 7. Sketch of the test fixture for measurement of dielectric parameters of sintered samples.

The test fixture is a rotationally-symmetrical structure. It comprises a standard SMA coaxial connector at the bottom. The inner conductor of the connector carries a thin metallic disc, which acts as the lower electrode of a parallel-plate capacitor. The upper electrode is a thick metallic disc, which has a screw thread whose pitch is 1 mm. A mating thread is cut in the outer wall of the chamber. The upper electrode can be removed from the chamber so that a ceramic sample can be inserted into the chamber. The upper electrode is placed back so that it lightly presses the sample.

The ceramic sample is cylindrical, its diameter is *d*, and the height is *h*.

All metallic parts of the chamber are made of brass, except for the coaxial SMA connector, which is made of gold-plated stainless steel. The dielectric of the connector is Teflon. A Teflon disk is placed under the lower electrode in order to restrict the pressure on the inner conductor of the SMA connector.

We use a vector network analyzer (VNA) Agilent E5061A to measure the reflection coefficient at the SMA connector. The VNA is calibrated using an SMA calibration kit. The reference plane is at the lower end of the SMA connector.

At lower frequencies, up to around several hundred MHz, the chamber is assumed to be small compared to the wavelength and the quasistatic approximation for the electromagnetic fields is applied. The chamber is numerically modeled using a similar approach as in [51, 52]. A set of integral equations for the total charges (free plus bound) is formulated based on the boundary conditions. The first subset of boundary conditions is for the potential at conductor surfaces. The second subset of boundary conditions is for the normal component of the electric field at dielectric-to-dielectric interfaces. This system of integral equations is solved using the method of moments [53] with a piecewise-constant approximation for the charge distribution. The Galerkin technique is applied for testing.

The integrals for the potential are double. The first integration is carried out analytically, using the complete elliptic integral of the first kind. For the second integration, an adaptive Gauss-Legendre formula. The Galerkin integration is implemented using a Gauss-Legendre formula applied to equal-length subsegments along the generatrix of the structure.

The normal component of the electric field is obtained by numerical differentiation of the potential. Thereby, the field segment is incrementally moved away, perpendicularly from its original position, and the potential is evaluated for two positions of this segment.

In the numerical model, the conductors are assumed to have a finite thickness. Hence, the surface density of the free charges on the conductors is extracted from the density of the total charges by multiplication by the relative permittivity of the surrounding dielectric. In comparison with the method used in [51, 52], this approach significantly improves the quality of the solution.

The dielectric losses of the ceramic sample are taken into account by using the complex relative permittivity. The complex capacitance of the chamber is extracted from the measured complex admittance and the complex permittivity of the sample is adjusted in the numerical model so that the computed capacitance matches the measured one. This adjustment involves several interpolations.

For smaller ceramic samples, a simpler procedure is possible. The complex capacitance is measured when the sample is present and when it is removed. The complex relative permittivity of the sample is thereafter evaluated from the difference of these two capacitances, assuming that the electric field within the sample is homogeneous.

The accuracy of the quasistatic approach is enhanced by shifting the VNA reference plane to the beginning of the chamber (Fig. 7). Additionally, a first-order correction is implemented for the parasitic inductance of the chamber. As the result, the measurements can be performed in the whole VHF frequency band (30–300 MHz) and even extended to 500 MHz. The measurement uncertainty is 2% for ε_r' and 0.003 for $\tan\delta$. At lower frequencies, the VNA noise becomes a problem, which jeopardizes measurements particularly below around 10 MHz.

For higher frequencies, we have developed full-wave models of the chamber in software WIPL-D [54] and HFSS [55]. The models include the feeding coaxial line, up to the reference plane for VNA measurements. In each model, we supply the geometrical dimensions of the chamber and the sample, as well as data for the conductors (brass, gold) and dielectrics (Teflon, air) of the chamber. We assume several values for the relative permittivity of the sample and sweep over the frequency to compute the reflection coefficient at the reference plane for VNA measurements. Finally, we interpolate the relative permittivity to obtain the best agreement with the measurements.

V. Examples of Measured Permittivities

We present two examples in order to illustrate how the dielectric parameters of ceramic materials are affected by the mechanical activation (Section II) and also demonstrate the results obtained by the measurement technique described in Section IV.

The first example is spinel ceramic ($MgAl_2O_4$) [56]. We examined two different powders. One was not activated and the other one was activated in a high-energy planetary ball mill for 60 min. The results of the particle-size analysis (PSA) are shown in Fig. 8. The average particle size d(0.5)

was 2.1 µm for the non-activated powder AM–0. After mechanical activation for 60 minutes, the average particle size decreased to about 1.3 µm. Likewise, d(0.1) decreased from 0.69 µm for AM–0 to 0.43 µm for AM–60. Interestingly, d(0.9) increased from 4.74 µm for AM–0 to 8.04 µm for AM–60. Milling also produced a bimodal particle-size distribution in the AM–60 powder with peaks in the distribution at about 0.8 µm and 5 µm. While the milling significantly reduced the average particle size, it also produced some agglomerates that were larger than in the starting powder.

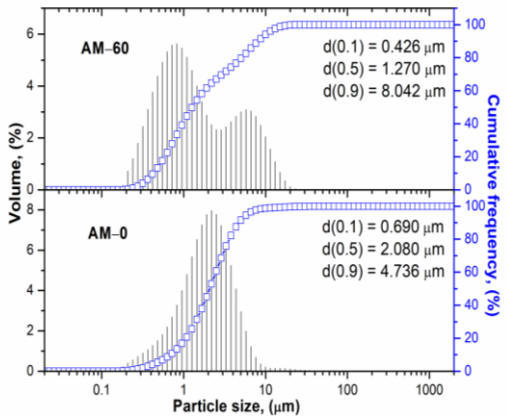

Fig. 8. PSA of the non-activated powder (AM–0) and powder activated for 60 minutes (AM–60).

Fig. 9a shows the relative permittivity and loss tangent of the material, sintered at 1400 ºC for 2h, when the starting powders (MgO and Al_2O_3) were not mechanically activated. These dielectric parameters are shown as a function of frequency in the range from 10 MHz to 500 MHz. The material is lossy; the loss tangent exceeds 0.3 at 10 MHz. The relative permittivity decreases with frequency, which is in accordance with the causality conditions.

Fig. 9b shows the results for spinel, also sintered at 1400 ºC for 2h, when the starting powders were activated. The relative permittivity is increased compared to the non-activated material and the loss tangent is smaller. The increased relative permittivity is in agreement with the increased density: the density of the non-activated material is 2.05 g/cm^3, whereas the density of the activated material is higher, 2.22 g/cm^3.

The second example is cordierite [57], which was mechanically activated. The milling times were up to 160 minutes. Also in this case, a strong correlation was found to exist between ε'_r and the sample density (ρ): the relative permittivity is higher for denser samples (i.e., for samples which have lower porosity), as shown in Fig. 10.

The data points in Fig. 10 closely follow the Lichtenecker-Rother logarithmic law of mixing [58]. The density of cordierite without pores is $\rho = 2.6\,\mathrm{g/cm^3}$, for which this fitting formula yields $\varepsilon'_r = 6.1$.

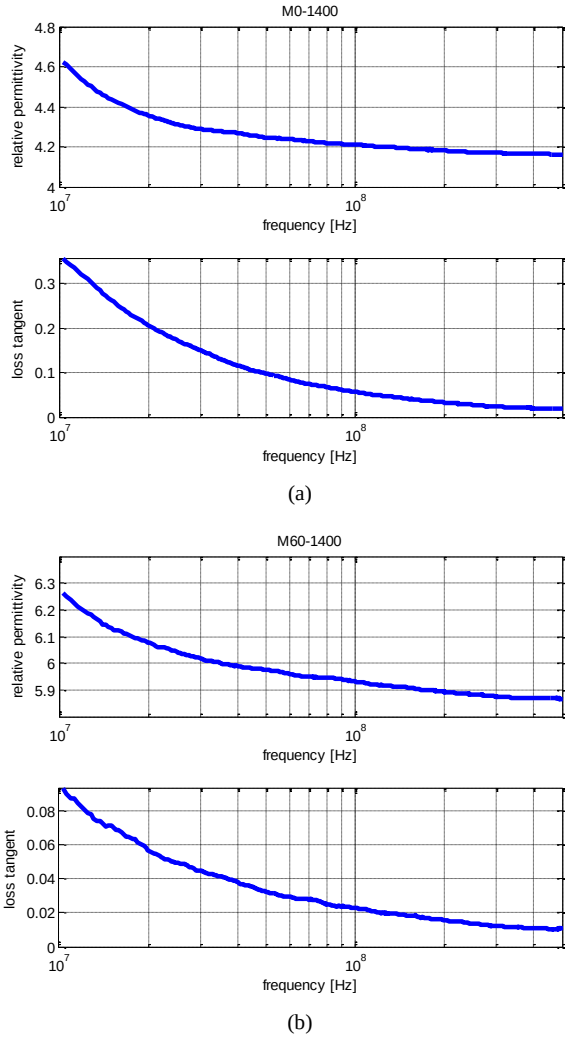

Fig. 9. Relative permittivity and loss tangent, as a function of frequency, for spinel when the starting powders were (a) not activated and (b) activated by milling for 60 minutes.

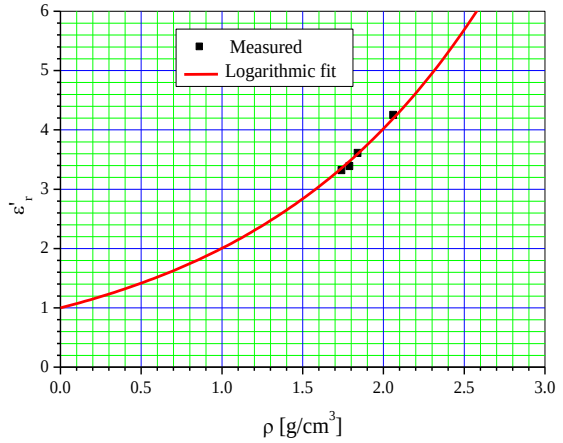

Fig. 10. Real part of the relative complex permittivity versus density for cordierite [57].

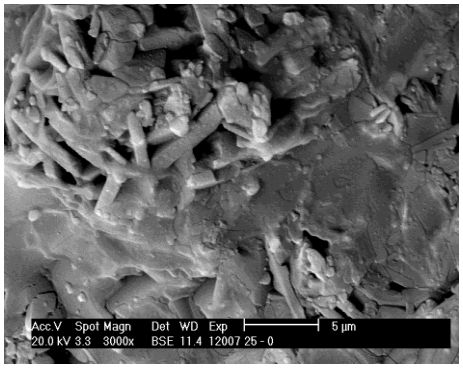
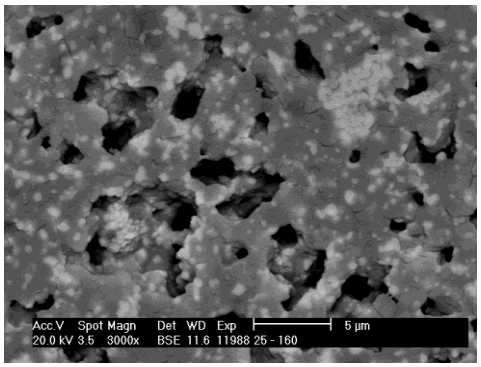


(a)



(b)

Fig. 11. SEM micrographs of two-step sintered powder mixtures: (a) MAS-0-S2 and (b) MAS-160-S2.

The average sample densities after the two-step sintering regime ranged from 60.3 to 74.8 % of the theoretical density. The scanning electron micrographs of the two-step regime sintered samples are shown in Fig. 11. The MAS-0-S2 sample (non-activated) consists of two different areas. One is a well sintered matrix and the other one is made of rod-like parts where the sintering process had not finished. This microstructure is a consequence of non-homogeneous mixture sintering. The sample MAS-160-S2 (activated for 160 minutes) has the highest relative density and the lowest relative open porosity. The obtained microstructures and densities after sintering are in a good accordance with the results of electrical measurements.

VI. Conclusions

Preparation conditions influence significantly the final structure and electrical properties of ceramic materials. An important goal is to obtain a ceramic material with nearly the full density and fine grains with a homogeneous distribution. The mechanical activation, as a pretreatment for the shaping and sintering process, is a very convenient way of powder preparation with a uniform particle-size distribution [59]. Processes such as increase in the number of contact and massive neck formation occur during the early stage of sintering. The neck growth is controlled by numerous diffusion mechanisms whose rates are determined by the total flux of atoms coming to the neck, suggesting that the dominant processes occur at grain boundaries.

Many functional properties of ceramics are also strongly influenced by the grain boundaries. From that point of view, electrical properties must be measured using AC techniques, so that the effects of grains and grain boundaries can be assessed separately.

Furthermore, sintering conditions can drastically change electrical properties. We considered the influence of the mechanical activation on the permittivity and the loss tangent of ceramic materials. We presented several examples demonstrating this influence. The results for the permittivity and the loss tangent were obtained using a newly developed measurement technique, which is revealed in the paper. The technique was designed to characterize relatively small samples of ceramic materials, without the need to metallize the surfaces of the samples. The electrical parameters in the VHF frequency band are computed from measured data using a quasi-static model. For higher frequencies, in the microwave region up to 10 GHz, we developed full-wave models, which are yet to be fully verified.

Electrical characteristics and phase transformation of Ho doped $BaTiO_3$ ceramics

Miloš Đorđević, *Student Member, IEEE*, Vesna Paunović, *Member, IEEE,* Vojislav Mitić, and Zoran Prijić, *Member, IEEE*

***Abstract*- The dielectric characteristics and phase transformation of Ho doped $BaTiO_3$ ceramics is investigated in this article. The concentrations of Ho_2O_3 in doped samples were ranged from 0.05 to 1.0 at% Ho. The investigated samples were prepared by a conventional solid state sintering procedure and sintered at 1320°C for 4 hours. For low dopants concentration (0.05 at% Ho), SEM analysis shows abnormal grain growth with the average size range between 10 μm - 30 μm. With the increase of dopant amount in samples causes decrease of average grain size, and for samples doped with 1.0 at% Ho, grain size range from less than 1 μm - 2 μm. The dielectric characteristics was measured in temperature range from 30°C to 180°C at different frequencies, from 100 Hz to 1 MHz. The dielectric constant has higher values for samples with lower concentration of additives (ε_r=4250 for 0.05 at% Ho/$BaTiO_3$, while ε_r=990 for 1.0 at% Ho/$BaTiO_3$ at Curie temperature). After initial high values at lower frequencies, ε_r decreases with frequency increase and reaches a constant value for f>20kHz. The Curie temperature at which the transition from the ferroelectric to the paraelectric region occurs ranges from 126°C to 130°C. For all investigated samples, it is characteristic that as the temperature increases, the tangent angle of losses increases. Curie-Weiss's law and modified Curie-Weiss law were used to calculate parameters such as Curie constant C and Curie temperature Tc, parameter γ which describing the diffusion and degree of nonlinearity of the change ε_r of the temperature above the Curie temperature and parameter δ which describing change εr of the temperature and frequency. In all the samples examined, a sharp transition from the ferroelectric to the paraelectric region at the Curie temperature is characteristic, which shows the value of the critical exponent of the nonlinearity γ from 1.01 to 1.07.**

Index Terms - $BaTiO_3$ ceramics; microstructure; electrical resistivity.

INTRODUCTION

Ferroelectric ceramics, most commonly tested for their practical applications, are $BaTiO_3$ ceramics. The reasons for such wide use of barium titanate are many. Barium titanate has a relatively low Curie temperature of T_C (120-130°C).

This allows the maximum dielectric permittivity in a temperature range in which it can be efficiently used (e.g. use in high-power converters) [1]. Based on this, the $BaTiO_3$ ceramic application area is very large and some of the examples are for electronic components such as multilayer ceramic capacitors, thermistors, piezoelectric sensors and PTC resistors [2], [3].

The dielectric properties of polycrystalline $BaTiO_3$ strongly dependent on the microstructure development, which depends on the type, concentration and the distribution of dopants.

In order to obtain $BaTiO_3$ ceramics with a high value of dielectric constant, it is necessary to establish high density, homogeneous and fine-grained microstructure, as well as uniform distribution of dopants and additives [4]-[6]. Two types of dopants can be introduced into $BaTiO_3$ lattice.

For the rare-earth ion incorporation into the $BaTiO_3$ lattice, the $BaTiO_3$ defect chemistry mainly depends on the lattice site where the ion is incorporated [7]. Depending on the size of the rare earth radius ions, which is in magnitude between the ionic radii Ba^{2+} or Ti^{4+} ions, rare earth cations such as Er^{3+}, Yb^{3+} Ho^{3+} and Dy^{3+} can occupy Ba or Ti positions in the perovskite $BaTiO_3$ structure [8], [9].

During cooling, $BaTiO_3$ ceramic passes through a series of phase transformations, from cubic to tetragonal ferroelectric phase at 1280°C-1300°C, to orthorhombic ferroelectric at 0°C, and further cooling to the rhombohedral ferroelectric phase at -80°C [10].

Additives have the effect of moving the Curie temperature or moving the maximum dielectric permeability value into a temperature range of doped $BaTiO_3$ ceramics, and that can be efficiently used. As the applied dopants influence the temperature of the phase transformation and on the Curie constant, it is best seen through the dependence of the dielectric constant on the temperature. For $BaTiO_3$ doped ceramics, phase transformation can have a very sharp transition from the ferroelectric to the paraelectric region, but also the diffusion phase transition ("relaxor" ceramics) can also occur [11].

To investigate the behavior of ferroelectrics in the paraelectric phase, in addition to the Curie-Weiss law, the modified Curie-Weiss relations that describe the deviations from the linearity $\varepsilon r = f(T)$ due to the diffuse phase transformation and the dependence of the dielectric constant on the frequency are also used.

The results of the influence of the additive concentration and the obtained microstructure on the dielectric properties of Ho doped $BaTiO_3$ ceramics are given in this paper. The

microstructure of samples was observed by scanning electron microscope (SEM). The variation of dielectric permittivity with temperature were measured in the temperature range from 30°C to 180°C and the frequency range from 100Hz to 1MHz.

EXPERIMENTAL PROCEDURE

Modified $BaTiO_3$ ceramics doped with 0.05, 0.1, 0.5 and 1.0 at% of Ho_2O_3 was obtained by conventional solid-state sintering method starting from pure oxide powders $BaTiO_3$ (Rhone Poulenc) and Ho_2O_3 (Fluka chemika). Starting powders are ball milled in ethyl alcohol for 24 hours. After milling the slurries were dried in an oven at 200°C for several hours until constant weigh and PVA was added as a binder. The milling powders were drying for several hours, and pressed into pellets 2 mm thick and 7 mm in diameter under 120 MPa. The pellets were sintered in air at 1320°C for 4 hours.

The microstructure of the sintered samples were observed by scanning electron microscope JOEL-JSM 5300 equipped with EDS (QX 2000S) system. Before samples were observing, electrical contacts were prepared by silver paste. The variation of electrical resistance with temperature were measured in temperature interval from 30°C to 180°C by using LCR meter Agilent 4248A at different frequencies, from 100Hz to 1MHz.

RESULTS AND DISCUSSION

Microstructure characteristics

The samples of $BaTiO_3$ ceramics doped with Ho_2O_3 are characterized by spherical and irregular polygonal grains.

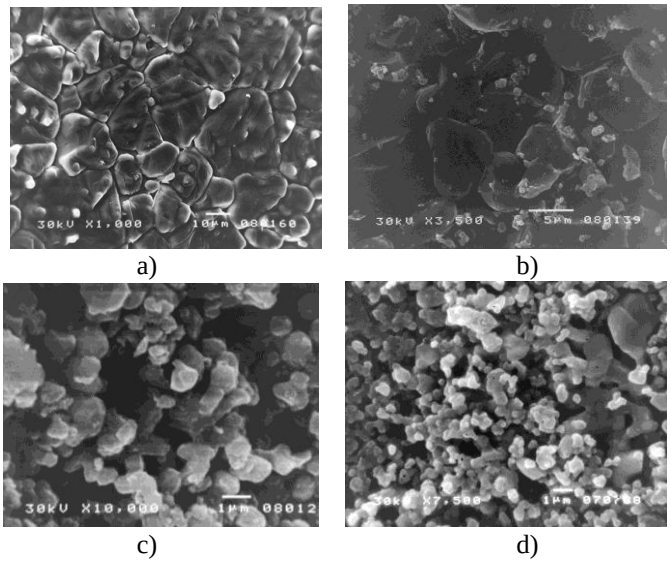

Fig. 1. SEM images of Ho doped $BaTiO_3$ ceramics sintered at Tsin=1320°C, a) 0.05 at%, b) 0.1 at%, c 0.5 at% and d) 1.0 at%.

The average grain size for samples doped with low content of Ho_2O_3 (0.05 at% Er) ranged from 10 μm to 30 μm (Fig. 1a)) for all measured samples. By increasing dopant concentration the grain size decreases. As a result, for 0.1 at% Ho of dopant the average grain size is from 5 μm to 15 μm (Fig. 1b)). With further increase of dopant concentration the average grain size decreases and for samples doped with 0.5 at% Ho is from 2 μm to 10 μm (Fig. 1c)), and for samples doped with higher dopant concentration (1.0 at% Ho), the average grain size is from the less than 1 μm to 2 μm (Fig. 1d)).

Such a microstructure is in accordance with the change of density of the investigated samples, which ranged from 82% to 91% of the theoretical density (TD). With the increase of dopant amount the increase of porosity is evident and density value decrease, so the highest density was for 0.05 at% doped samples (91% TD). The lowest value of density (82%) was measured for samples doped with 1.0 at% Ho.

EDS analysis of samples doped with 0.05 at% Ho_2O_3 did not reveal any Ho-rich regions, which indicated a uniform incorporation of dopants within the samples (Fig. 2a)).

EDS analysis cannot detect the additive content less than 1.0 at% Ho unless an inhomogeneous distribution or segregation of additive is present. The increase of dopant concentration leads to the appearance of Ho-rich regions (Fig. 2b)). These areas, rich of additives, are also characteristic for fine-grained microstructure.

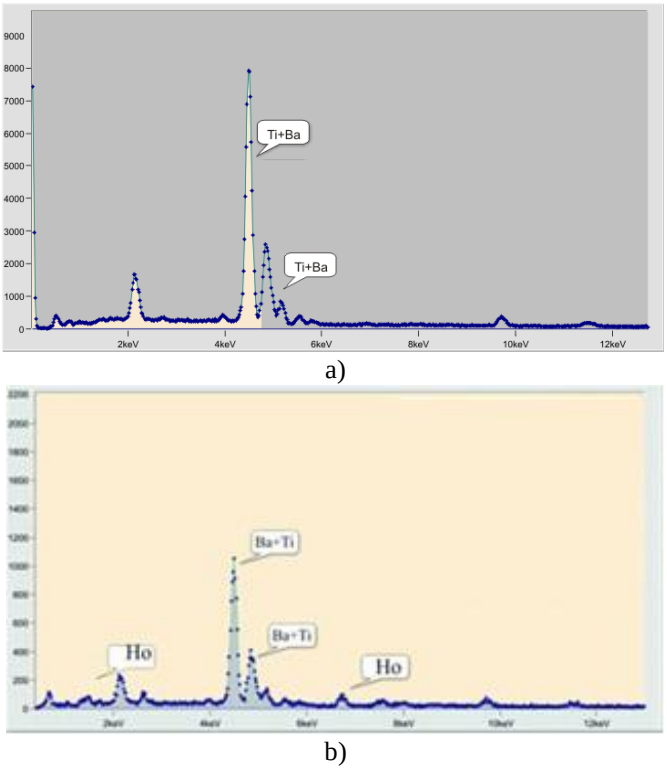

Fig. 2. EDS analysis of Ho doped $BaTiO_3$ sintered at 1320°C: a) 0.05 at% Ho-$BaTiO_3$, where no Ho is detected and b) Ho-rich regions in 1.0 at% Ho-$BaTiO_3$.

Electrical characteristics

The influence of the additive concentration and obtained microstructure on dielectric permittivity of the samples doped with Ho_2O_3 can also be examined through dependence of the dielectric permittivity on the temperature and frequency (Fig. 3 and Fig. 4). In this manuscript were investigated on

temperature in temperature range from 30°C to 180°C and frequency range from 100 Hz to 1 MHz. Based on the curves of dielectric constant dependence on temperature, it can be seen that the highest dielectric constant values at the Curie temperature ε_r = 3530 show samples with a concentration of 0.05 at% Ho. The lowest dielectric constant values at the Curie temperature have samples with the highest concentration of additives (1.0 at% Ho) and it is ε_r = 990.

Curie temperature (*Tc*) in which the transition from ferroelectric to paraelectric phase occur were in the range from 128°C to 130°C and it is lower relative to *Tc* undoped $BaTiO_3$ ceramic (*Tc* = 132°C).

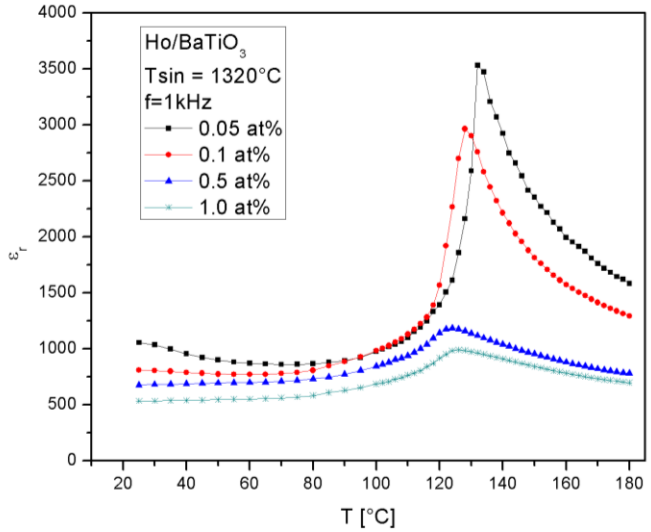

Fig. 3. The dependence of dielectric permittivity on temperature for the different doping concentration (0.05 – 1.0) at% Ho.

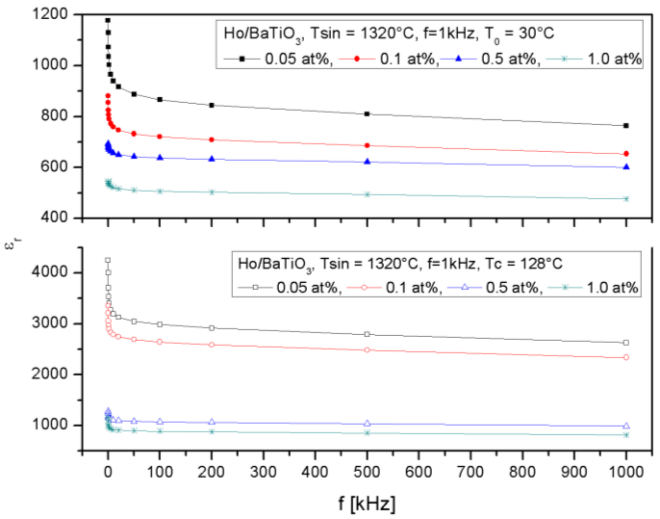

Fig. 4. The dependence of dielectric permittivity on frequency at room and Curie temperature.

The dielectric permittivity dependence on frequency at room and Curie temperature is shown in Fig. 4. As can be seen, the highest values of dielectric permittivity were for measured samples doped with lower content of dopant (0.05 at%). It has also been observed that the measured samples have higher values of dielectric permittivity at lower frequencies. Highest value of dielectric permittivity at room temperature (T = 30°C) has ε_r = 1177 for samples doped with 0.05 at% Ho, and at Curie temperature value of dielectric permittivity has ε_r=4250 for the same content of dopant. For the all measured samples it was noticed that after the initial high values dielectric permittivity values decreases increasing of values of frequency and achieves constant value for f > 20kHz.

On Fig. 5. it can be seen dependence of tangent of losses on temperature for all measured samples at frequency of 1 kHz. The dielectric losses of the measured samples (*tg δ*) with temperature have values ranging from 0.017 to 0.57. For the all measured samples is characteristic that as the temperature increases, the tangent loss increases. The smallest increase in the tangent losses is for samples with a concentration of additives of 1.0 at%, and the highest increase in samples with a concentration of additives of 0.05 at% Ho. Similar dependencies have been obtained for other frequencies.

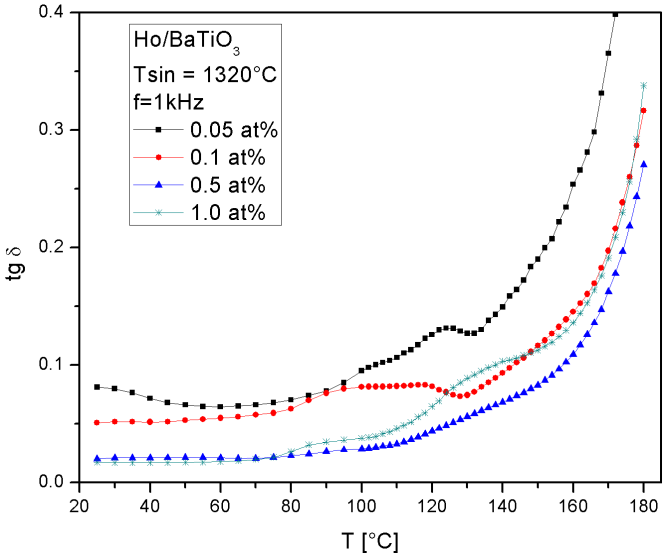

Fig. 5. The dependence of tangent (*tg δ*) losses on temperature for the different doping concentration (0.05 – 1.0) at% Ho at 1kHz.

Dielectric permittivity in ferroelectrics changes with temperature, reaches maximum value at Curie temperature and decreases with further increase of temperature. The dependence of dielectric permittivity on the temperature in the paraelectric region, i.e. in the area above Curie temperature, can be described by Currie-Weiss law:

$$\varepsilon_r = \frac{C}{T - T_0}. \qquad (1)$$

where is *C* – Currie constant, *T* – temperature, and T_0 – Currie-Weiss temperature.

By fitting the dependence of the reciprocal value of dielectric permittivity on the temperature, as shown in Fig. 6, the values of Curie-Weiss temperature T_0 are obtained. The Curie-Weiss temperature T_0 has a lower value than Currie temperature (*Tc* = 126°C - 130°C) for all measured samples. The highest value for T_0 was obtained for samples doped with 0.05 at% (T_0 = 93.05°C), and the lowest T_0 value for samples

was doped with 1.0 at% (T_0 = 10.22°C). Table I gives the values of Currie-Weiss temperature for all measured samples.

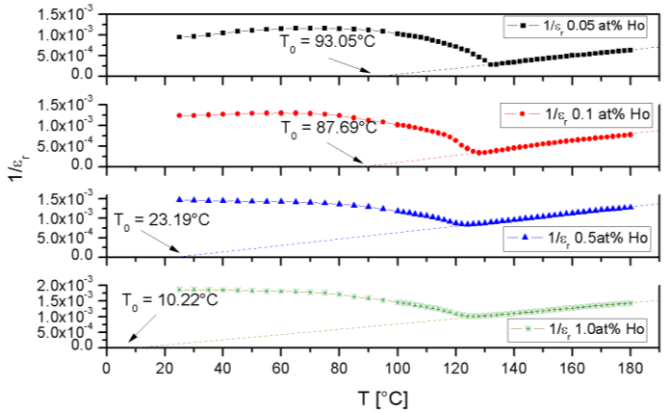

Fig. 6. The reciprocal value of the dielectric permittivity in the function of the temperature.

Based on the Currie-Weiss law, the values of the Curie constant for all measured samples are calculated. The value of Curie constant decreases with increasing additive concentration (Fig. 7) so that the highest value of the Curie constant is calculated for samples with additive concentration of 0.05 at% Ho ($C = 2.15 \cdot 10^5$ K), and the lowest for samples with an additive concentration of 1.0 at% Ho ($C = 5.9 \cdot 10^4$ K). The samples with highest value of C are characterized by fine-grained microstructure and higher sample density. The values for the Curie constant are in agreement with the change in the density of the tested samples as well as with the microstructural characteristics.

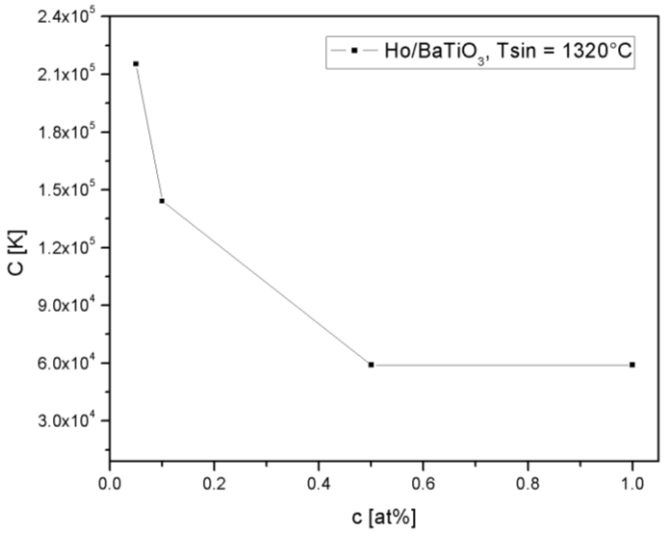

Fig. 6. Curie constant in the function of additive concentration.

For all the measured samples, a sharp transition from the ferroelectric to the paraelectric region is characteristic, as is the sudden increase of the dielectric permittivity at the Curie temperature. This fact can be confirmed by the ratio of the dielectric constant at the Curie temperature (ε_{rmax}) and at room temperature (ε_{rmin}), i.e. ($\varepsilon_{rmax}/\varepsilon_{rmin}$) (Table 1). The highest dielectric constant ratio was calculated for samples doped with 0.1 at%, $\varepsilon_{rmax}/\varepsilon_{rmin}$ = 3.66, and the lowest ratio of samples doped with 0.5 at%, 1.75.

TABLE I
DIELECTRIC PARAMETERS FOR HO/$BaTiO_3$ CERAMICS

	ε_r at T=300K f=1kHz	ε_r at T_C f=1kHz	Tc [°C]	$\varepsilon_{rmax}/\varepsilon_{rmin}$	T_0 [°C]	C [K] $\cdot 10^5$
0.05 at% Ho	1177	4250	130	3.35	93.05	2.153
0.1 at% Ho	880	3356	128	3.66	87.69	1.442
0.5 at% Ho	693	1285	124	1.75	23.19	0.591
1.0 at% Ho	545	1162	126	1.98	10.22	0.590

In order to explain the deviations from linearity of the Curie-Veiss law (1), in the investigated samples, Kirillov and Isupov proposed the equation [12,13]:

$$\frac{1}{\varepsilon_r} - \frac{1}{\varepsilon_{r\max}} = \frac{(T - T_{\max})^2}{2\varepsilon_{r\max}\delta^2}. \quad (2)$$

where ε_r is the dielectric constant, ε_{rmax} dielectric constant on Tc and δ parameter describing the change of ε_r from temperature and frequency. In addition to the Curie-Weiss law for testing the behavior of ferroelectrics in the paraelectric phase are also used modified Curie-Weiss relations that describe the deviations from linearity $\varepsilon_r = f(T)$ due to the diffuse phase transformation and the dependence of the dielectric permittivity on the frequency.

Using modified Curie-Weiss law:

$$\frac{1}{\varepsilon_r} = \frac{1}{\varepsilon_{r\max}} + \frac{(T - T_{\max})^{\gamma}}{C'}. \quad (3)$$

where the C' constant is similar to the Curie constant, a critical exponent of nonlinearity γ is determined, which shows a deviation from the linear dependence of the dielectric permittivity ε_r on the temperature in the paraelectric region. Based on linear fitting of curves $ln(1/\varepsilon r\text{-}1/\varepsilon r_{max})$ in function of $ln(T\text{-}T_{max})$ was obtained as a slope of the right, and the graphical representation for all samples is illustrated in Fig. 7.

The value of the critical exponent of the nonlinearity γ for measured samples ranges from 1.001 for 0.05at% Ho doped samples to 1.07 for samples doped with 1.0at% Ho (table 2). These values are in accordance with the experimental data, because for these samples there is a characteristic sharp transition from the ferroelectric to the paraelectric region indicating a structural phase change.

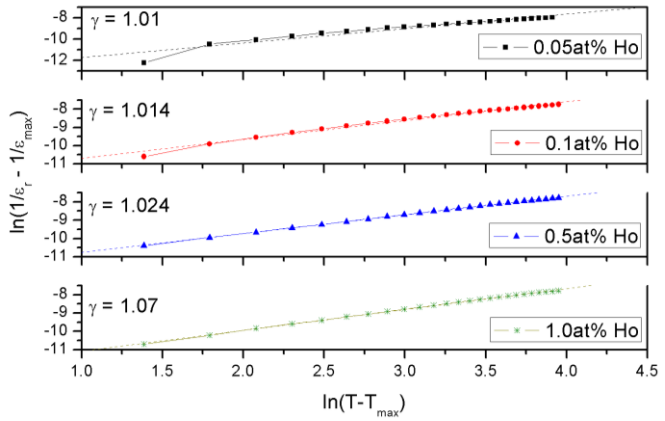

Fig. 7. Dependence $ln(1/\varepsilon_r - 1/\varepsilon_{rmax})$ of $ln(T-T_{max})$ for measured samples.

On the basis of equations (2) and (3), C' and δ are calculated which is a measure of the diffusion phase transition. As can be seen from Table 2 with increasing concentration of Ho_2O_3, the C' constant increases, so that the highest values are calculated for 1.0 at% Ho.

TABLE II
DIELECTRIC PARAMETERS FOR HO/BATIO$_3$ CERAMICS

	C' [K] $\cdot 10^5$	γ	δ
0.05at% Ho	1.32	1.01	22.53
0.1at% Ho	1.11	1.014	24.07
0.5at% Ho	1.29	1.024	43.38
1.0at% Ho	1.33	1.07	46.89

On Fig. 8 is shown the dependence of specific electrical resistance on temperature for all measured samples at a frequency of 1 kHz. The values of specific electrical resistance (ρ) with temperature have at low temperatures a slight increase in all measured samples up to Curie temperature, and above this temperature (128-130°C), starting with samples with the lowest concentration of additives (0.05 at% Ho), up to samples with the highest concentration (1.0 at% Ho) there is a sudden increase in specific electrical resistivity. For other frequencies on which samples were measured, similar addictions were obtained.

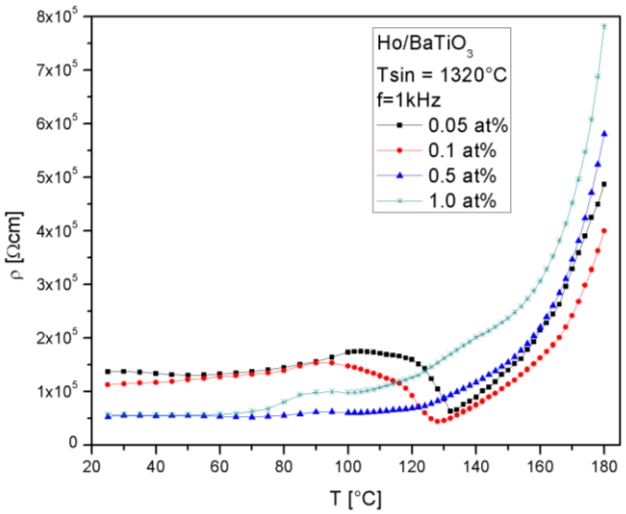

Fig. 8. The specific electrical resistivity on temperature for the different doping concentration (0.05 – 1.0) at% Ho at 1kHz.

IV. CONCLUSION

In this article the dielectric characteristics and phase transformation of Ho_2O_3 doped of $BaTiO_3$ ceramics has been investigated. Microstructural studies have shown that for lower concentration of dopant (0.05 at% Ho) characteristic spherical and irregular polygonal grain growth with the average size range between 10-30 μm for samples sintered at 1320°C. The increase of dopant concentration in samples, leads to decrease of average grain size and for samples doped with 1.0 at% Ho, the average grain size range from less than 1 μm - 2 μm. The highest value of dielectric permittivity at Curie temperature has measured samples ε_r = 3530 with a concentration of additives of 0.05 at% Ho. With increasing of dopant content, value of ε_r decreasing, and lowest value has measured for high dopant content (1.0 at Ho), εr=990. Value of Curie temperature was ranged from 128° to 130°C. Tangent angle of losses was in range from 0.017 to 0.57. Based on the Curie-Weiss law, the parameters such as the Curie-Weiss temperature (T_0) and the Curie constant (C) are determined. The highest value of the Curie constant is calculated for Ho doped BaTiO3 ceramics with additive concentration of 0.05 at% Ho (C = $2.95 \cdot 10^5$ K), and the lowest for samples with a concentration of additives 1.0 at% Ho ($C = 0.590 \cdot 10^5$ K). The critical exponent of non-linearity γ was in the range from 1.01 to 1.07, which is in accordance with the experimental data, because for all the samples a sharp transition from the ferroelectric to the paraelectric region is characteristic.

Surface properties of polycrystalline diamonds for advanced applications

Sandra Veljković, *Student Member, IEEE*, Vojislav Mitić, Vesna Paunović, *Member, IEEE*, Goran Lazović, Markus Mohr and Hans Fecht

***Abstract* – The development of new materials as well as improvement of already known materials characteristics, can significantly contribute to the progress in the development of different areas. In that sense, polycrystalline diamonds are becoming more and more interesting because of their wide application. Considering that this material has an extreme potential, the research in this area is intense, and in this paper are presented the most important applications related to engineering. Intensive research of surface structure can contribute to the better insight of polycrystalline diamonds properties. An analysis of surface structure of nanocrystalline diamonds obtained by chemical vapor deposition method is presented in this paper.**

Index Terms – polycrystalline diamonds; application; MEMS; surface properties

I. Introduction

Diamond is one of allotropic modifications of carbon and due to its specific structure, has a very wide application [1]. Probably, its most known use is in jewelry, but it also has applications in medicine, in various industries for cutting, grinding, drilling and polishing [2]. Besides that, there is a very important use of diamonds in microelectromechanical systems (MEMS), microelectronics and in other areas.

However, natural diamonds are rear, expensive and it is hard to find them in proper sizes and shapes, which represents a limiting factor in their application. For that reason, the discovery that diamonds can be artificially synthesized was revolutionary. The first successful synthesis was achieved in the middle of the last century. The conditions in which diamonds are created in nature are artificially simulated: under high pressures (~GPa) and at high temperatures, which are about 1200°C. These parameters are used for the oldest technique for diamond synthesis, named high pressure high temperature (HPHT). Diamonds created by HPHT are very similar to natural diamonds. Although this technique is very effective, diamonds which are similar to stone are not applicable in engineering. For that reason, a better solution is chemical vapor deposition (CVD) method, by which diamonds can be created as thin films for covering different surfaces and shapes.

II. Natural Diamonds

Characteristics and properties of natural diamonds are the result of their specific structure, which is presented in Fig. 1a. It shows a unit diamond cell where each carbon atom is linked to the four nearest neighbors. The bond is made by sp^3 hybridized orbitals with angles of 109.5° between all neighbor bonds (Fig. 1b). Two intermediate surface-centered cubic lattices, which are shifted one of other one-quarter of its length can be seen in the diamond crystal structure. Each unit cell has eight atoms.

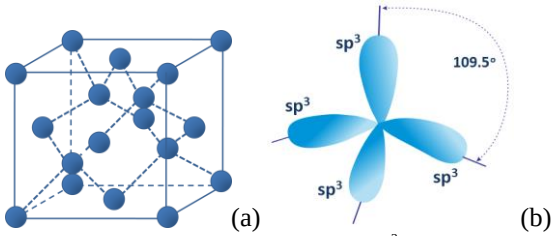

Fig. 1. (a) Cristal structure of diamond and (b) sp^3- hybrid orbitals.

Due to its structure, diamond is the hardest material on Mohs scale with the value of 10; it has the highest melting temperature which is 3547°C and the lowest molar entropy of 2.4 J mol^{-1} K^{-1}. Similarly, mechanical properties of diamonds are very interesting. Symmetrical tetrahedral structure and relatively short links between carbon atoms cause a very high value of Young's modulus – 1050 GPa. Also, monocrystalline diamond has a high fracture strength, about 2.8 GPa [3], which is by far the highest fracture strength value of all materials which are used for micro-mechanical purposes.

Despite great qualities of natural diamonds, it is not profitable to use them in mass production due to the price and complex processing. For that reason, diamond synthesis was a significant discovery, as it became possible to apply diamond layers on different materials and shapes.

III. Application of Polycrystalline Diamonds

A standard procedure for creating polycrystalline diamonds is the CVD technique. In this way, diamonds which are obtained are microcrystalline diamonds (MCD) and their grain size order of magnitude is micrometric. The main

characteristics of these layers are that they are very rough and have a very low resistance to fracture which limits their application. Further development and improving of this technique, made it possible to control the size of grain. Different forms of diamonds have been developed (with smaller grains) like nanocrystalline diamond (NCD) and ultra-nanocrystalline diamond (UNCD). These diamond materials have different structures and uses, but, what is the most important, they have significantly better characteristics in terms of mechanical strength and tribological properties in relation to MCD.

An efficient method for applying a diamond film of very high quality on large areas is to use hot filaments for the CVD method. There are variations of this method, but only a few variations are commercialized and applied for coating of tools for machine processing, cutting or surface protection.

The progress in development of the CVD method enabled control of the grain size, from micrometric to nanometric size. Grains, despite of their size, are always separated by non-diamond material such as graphite and C-H bonds with sp^2 and sp^3 hybridized carbon [1]. For that reason, any variation in the grain size of crystal can lead to a major impact on the total amount of atoms which are in contact with grain boundaries. In that sense, depending on the microstructure, the properties can be determined, and thus, the application of this materials.

Unlike natural diamond, which is an excellent electrical insulator with electrical resistivity of 10^{12}-10^{16} Ωcm, polycrystalline diamonds are very good electrical conductors and their conductivity varies between 10^{-4} and 300 S/cm [4]. For that reason, many intensive researches of electrical conductivity of polycrystalline diamonds can be found in literature. These novel materials are very interesting for application in MEMS, because of their mechanical and electrical properties. There is a requirement for the application of MEMS in sensitive and specific conditions [5].

Considering that polycrystalline diamonds have very good characteristics, their application in MEMS components is more frequent. The newest researches are related to finding the way to replace MEMS components in sensors with nanoelectromechanical systems (NEMS). With that replacement, there is a possibility to increase the resonant frequency and thus, the sensitivity of the sensor structure. NEMS structures can be made of different materials and because of that, there is a possibility to optimize individual properties such as hardness, low dissipation, compatibility with the work area, easy way for producing and better integration [6].

Structural properties of the high conductivity UNCD were especially investigated in order to determine the origin of electrical conductivity. During researching, it was observed that a small amount of nano-graphite exists between diamond grains. The mechanism which is responsible for conductivity in UNCD is attributed to the effect of πsp^2 bounds at the grain boundaries. The connection between structural properties of sp^2 carbon bounds and specific conductivity is observed. It can be said that the specific conductivity is firstly affected by structural properties of grain boundaries. Conductivity of thin films at room temperature can be explained by very low activation energies (meV), of sp^2 carbon bounds.

One of possible uses of polycrystalline diamonds is in radiofrequency (RF) MEMS resonators, and these materials were examined for this application [7]. The scanning electron microscopy (SEM) images of polycrystalline diamonds structures are shown in Fig. 2.

Also, the interest in the application of polycrystalline diamonds in sensors (piezo-resistant, temperature, gas and biosensors) has been increased due to their unique combination of properties [8]. Among other properties, they are chemically inert, resistant to corrosion, they have flexible modification of the surface, but the most important is that they are not toxic for humans and animals.

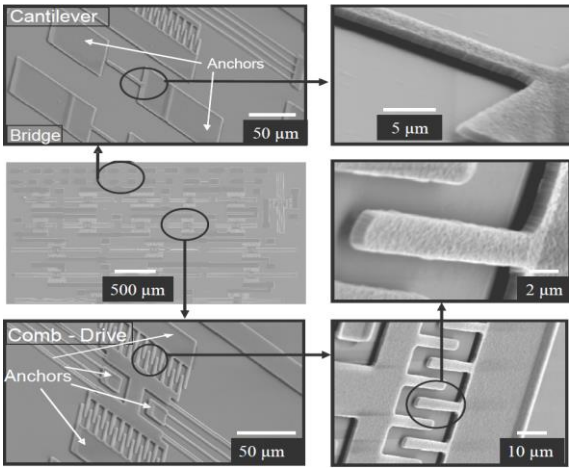

Fig .2. SEM image of polycrystalline diamond structures [7].

Fig. 3. presents the process of diamond probes creation, which have an undoped diamond layer (10^7 Ω-cm) and it serves as an insulator. The diamond layer which is doped with boron (10^3 Ω-cm) is used for bonds and electrodes.

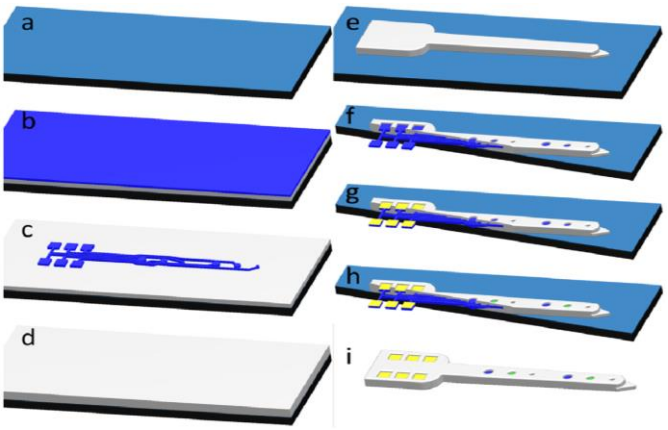

Fig. 3. Process of forming diamonds probes: (a) Si/SiO_2 substrate (b) undoped and doped diamond growth; (c) etching of doped diamond layer; (d) growing of undoped diamond layer; (e) etching undoped diamond layer for shaping probe; (f) undoped diamond etch to expose pads and electrodes; (g) gold bonding; (h) optional diamond functionalization; (i) release of probes in HF [8].

Fig. 3a illustrates Si/SiO_2 substrate, in 3b grow of a doped diamond layer can be seen and 3c shows etching of a doped diamond layer in order to define pads and electrodes. Next, 3d to 3f represent the growing and etching of an undoped diamond layer because probes and electrodes should be formed. Gold bonding and release of probes in HF are shown in 3g to 3i parts of the figure.

The usage of polycrystalline diamonds in the mechanical industry is very often, and especially for cutting, drilling or treating materials which are very complicated for processing such as carbon fiber reinforced plastics, plastic foils with metal additives. Also, one very interesting application of NCD is application in industry. For example, the tool of carbide tungsten is coated with NCD or NCD cutter blade for plastic films. In both cases NCD layer significantly extends the lifetime of the tool. The optical and thermal properties of microcrystalline diamonds with large grains are very useful for optical windows (for high–power laser window, vacuum windows, microwave windows) or head spreaders. Thick free-standing diamond disks up to several hundreds of micrometers can be grown and mechanically polished in order to achieve smooth surfaces.

In terms of tribological properties, the high wear-resistance and the low friction coefficient of diamond have very important role. NCD diamonds with smooth surfaces and high mechanical stability are excellent as the surface protective layer. The high shock and wear-resistance becomes highly effective when it finds application in bearings, pump seals or NCD-coated Si_3N_4 spheres. These spheres are used because of tribological properties, to improve their reliability and lifetime. Furthermore, the precise grow and microfabrication of NCD enabled the production of structures which are completely made of diamonds. Examples of these components are atomic force microscopy (AFM) probes which have a performance comparable to standard probes but with over 100 times lower wear rate [1].

The combination of the high wear-resistance and the low friction coefficient of smooth diamond surface is ideal for micromechanical systems. Very interesting and novel application of these materials is found in mechanical watch movements where important parameters are reliability, lifetime and accuracy. The production of mechanical watches represents one of few traditional crafts standing opposite to ever-increasing automation and mass production, which are increasingly present. However, traditional materials such as steel, nickel and ruby which are used in traditional manufacturing, now can be replaced with silicon and synthetic diamonds. The main aim of watch manufacturers is to produce the oil-free watch mechanism, which explains the demand for materials with very good tribological properties [9].

IV. Analysis of Polycrystalline Diamonds Surface

Fig. 4. represents a SEM image of polycrystalline diamonds obtained in the Institute of Functional Nanosystems in Ulm University, Germany. Wafers with a diameter of 6 inches were used for substrate silicon. The crystallographic orientation of these wafers was <100>. This sample was grown using the CVD method, but before growing the substrate was pre-treated. The solution which was obtained with container-shock synthesis, contained particles of diamonds. The average value of particles was about 30 nm. Clusters which were formed in this way had dimensions less than 100 nm. The substrate was ultrasonicated for almost 30 seconds and afterwards washed in isopropanol and deionized water. Diamond seeds were used for further initiation of grow nanocrystalline diamond films.

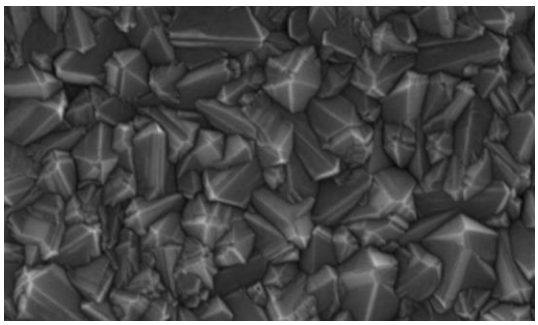

Fig. 4. SEM image of polycrystalline diamond surface.

In the production process of nanocrystalline diamond films CameCon CC800/Dia a reactor with wolfram filaments was used. The setup used for the CVD method contains a gas-cabinet in which there were CH_4, H_2 and several other gases. The source of gases was connected via mass flow controllers to the vacuum chamber. In the chamber, six rows for hot filaments and five positions for substrate could be located, which leads to 3D deposition. The pressure in the chamber can be reduced up to 1 Pa. In the vacuum-chamber there was a gas-shower which shall distribute the gas flow over the whole chamber cross-section. On the gas shower, were also mounted the filament holders which hold the wolfram filaments. Those were heated by an electric current to around 2000°C. The sample was held by a sample holder and the pressure in the chamber was controlled by a vacuum pump and a butterfly valve. The gas pressure during the process was 2000 Pa, while the hydrogen flow rate was set to 1500 sccm (standard cubic centimeters per minute) and the CH_4 flow to 20 sccm (1.3% CH_4/H_2). The process duration was 5 hours.

In order to visualize and analyze data, a modular program for scanning probe microscopy was used. In Fig. 5 is presented 3D view of the polycrystalline diamond surface of a

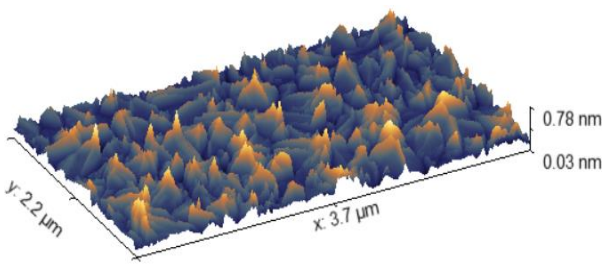

Fig. 5. 3D view of polycrystalline diamond surface.

grown film. Dimensions of the analyzed part of the surface are 2.2 μm and 3.7 μm, while the height of grains is in the range from 0.03 nm to 0.78 nm.

For further analysis standardized one-dimensional texture parameters in x and in y dimension were evaluated separately. In Fig. 6 are denoted specific A and A' (horizontal) and B and B' (vertical) directions for which the evaluation was performed. In the same picture, on the right side, can be observed a scale on which the shades of gray show the height of grains. The darkest gray represents the smallest height and the brightest gray represents the heights value of the grain. Obtained results are presented in figures 7 and 8.

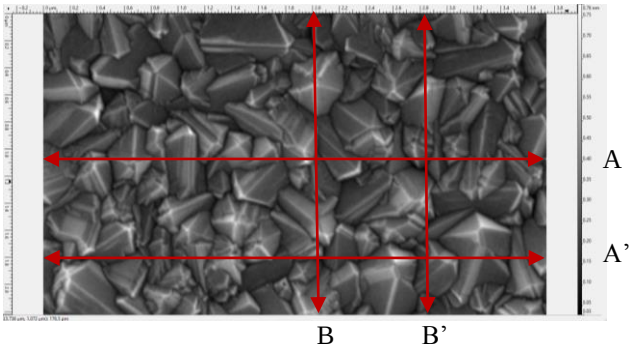

Fig. 6. Specific A and B directions for which evaluation was performed.

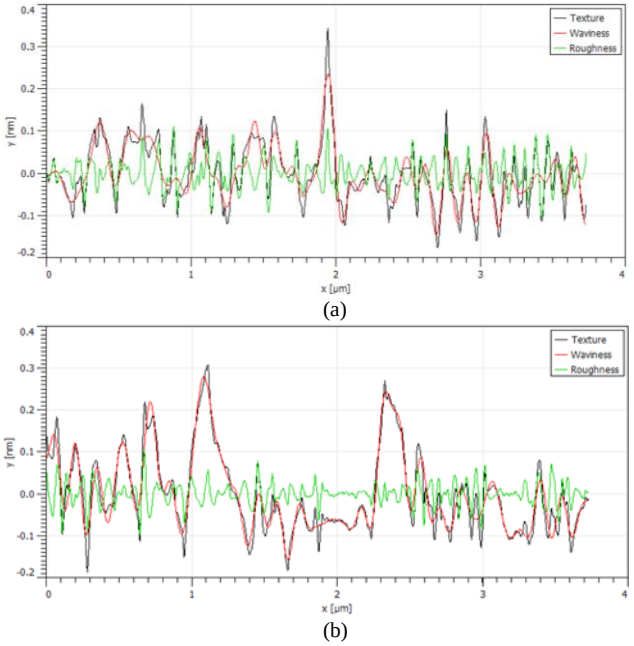
The one-dimensional texture is split to waviness (the low-frequency components defining the overall shape) and roughness (the high-frequency components) at the cut-off frequency. This frequency is specified in the units of the Nyquist frequency, that is the value of 1.0 corresponds to the Nyquist frequency. It is assumed that the mean value of r_j is zero, i.e.

$$r_j = z_j - \bar{z}. \quad (1)$$

where r_j is roughness, z_j is pixel-centered vertices and $\bar{z}$ is the mean value of z.

In Fig. 7. and Fig. 8. it can be seen that the texture and waviness are practically the same for all directions. The most pronounced peaks correspond to the highest parts of the grains for the chosen direction. Although, the waviness and texture are unique for any chosen direction, their values vary approximately from -0.2 nm to almost 0.4 nm for the presented directions. Maximal values of texture and waviness correspond to the highest parts of grains. It can be noticed that in direction A only one grain is dominant, while in direction A' several gains stand out and that caused the appearance of several peaks in Fig. 7b. Although, in direction B and B' there is almost the same number of prominent grains, in direction B' one grain (at position on 0.5 nm) is dominant.

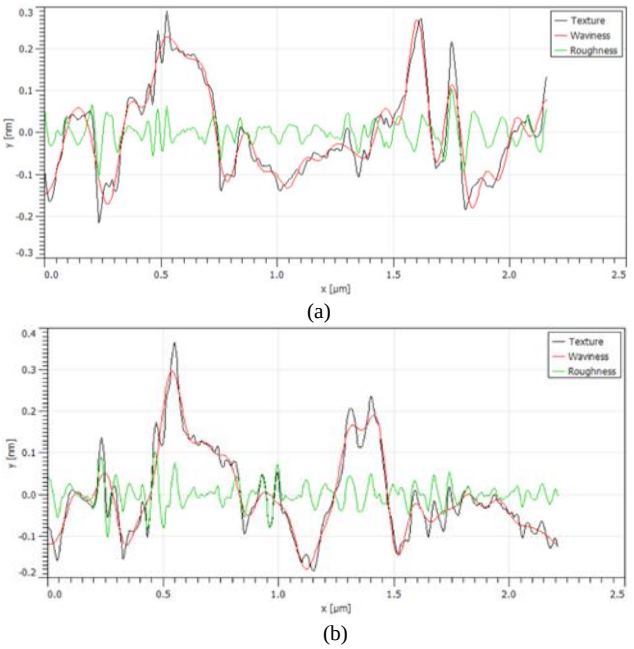
Also, Fig. 7. and Fig. 8. display that roughness as a component of surface texture, quantified by the deviations in the direction of the normal vector of a real surface from its ideal form, vary in all directions. In analyzing of surface roughness is typically considered to be the high-frequency component of a measured surface. However, in practice it is often necessary to know both the amplitude and frequency to ensure that a surface is fit for a purpose. Roughness is often a good predictor of the performance of a mechanical component, since irregularities may affect the properties of diamond films. Mechanical properties like Young's modulus and hardness strongly depend on grains size and structure. A detailed analysis of surface characteristics is also very important considering that pressure and gas mixture strongly influence the grain size grow. By varying these growth parameters, it is possible to influence properties of polycrystalline diamond films.



(a)

(b)

Fig. 7. Texture parameters of polycrystalline surface in A (a) and A' (b) direction.



(a)

(b)

Fig. 8. Texture parameters of polycrystalline surface in B (a) and B' (b) direction.

Additional parameters which can be useful for analysis are Root Mean Square Roughness (R_q,), the Amplitude Distribution Function (ADF), the Bearing Ratio Curve (BRC) and Skewness (R_{sk}).

The Root Mean Square Roughness represents the average of the measured height deviations taken within the evaluation length and measured from the mean line:

$$R_q = \sqrt{\frac{1}{N}\sum_{j=1}^{N} r_j^2} \tag{2}$$

where N is the number of samples along the assessment length. The value of this parameter R_q for the A direction is 33.79 pm.

The amplitude distribution function is a probability function that gives the probability that a profile of the surface has a certain height z at any position x. Obtained results for this parameter for the A direction are presented in Fig. 9.

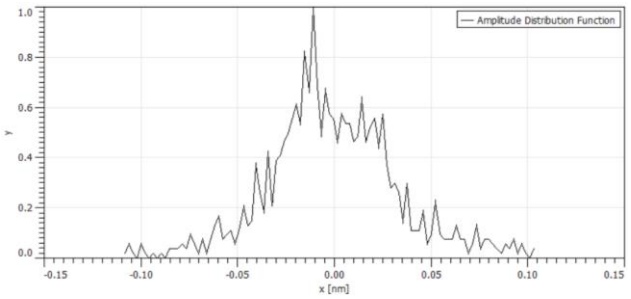


Fig. 9. The amplitude distribution function of polycrystalline surface in A direction.

The Bearing Ratio Curve is related to ADF, it is the corresponding cumulative probability distribution and it sees much greater use in surface finish. The bearing ratio curve is the integral (from the top down) of ADF.

Skewness is a parameter that describes the shape of ADF. Skewness is a simple measure of the asymmetry of ADF, or, equivalently, it measures the symmetry of the variation of a profile about its mean line which can be calculated by:

$$R_{sk} = \frac{1}{NR_q^3}\sum_{j=1}^{N} r_j^3 \tag{3}$$

The value of this parameter R_{sk} for the A direction is 0.1597.

V. Conclusion

Excellent electrical, thermal, mechanical and tribological properties are the reason why polycrystalline diamonds can be applied in many areas, in industry, medicine and especially for advanced electronics. Polycrystalline diamonds have a very important role in microelectronic and microelectromechanical systems as material used for sensors and probes. It is necessary to be familiar with characteristics of polycrystalline diamonds in order to improve current applications and also, to develop new ones. Considering that mechanical properties like the Young's modulus and hardness strongly depend on grains size and structure, a detailed analysis of surface characteristics, which includes various parameters, is also very important. Having in mind that pressure and gas mixture have a strong influence on the grain size grow, it is necessary to carefully investigate variations in these parameters.

In this paper an analysis of the polycrystalline diamond surface structure was performed. It was observed that for chosen directions, the texture feature is similar to the waviness. Although, waviness and texture are unique for any direction, their values are almost the same for the chosen directions and vary approximately from -0.2 nm to almost 0.4 nm. By varying growth parameters, it is possible to influence the properties of polycrystalline diamond films for specific applications.

Transport parameters of Ar^+ in Ar/BF_3 mixtures

Željka Nikitović

Abstract— **In this paper we present a cross section set for Ar^+ in Ar/BF_3 mixtures where existing experimentally obtained data are selected and extrapolated. A Monte Carlo simulation method is applied to accurately calculate transport parameters in hydrodynamic regime. We discuss new data for Ar^+ ions in Ar/BF_3 mixtures where mean energy, flux and bulk values of reduced mobility and other transport coefficients are given as a function of low and moderate reduced electric fields E/N (E-electric field, N-gas density).**

Key words— Ar/BF_3 mixtures, positive ions Ar^+, Monte Carlo simulations.

I. INTRODUCTION

Cold plasmas are frequently used in new technologies where they open up possibilities of non-intrusive production or modification of various substances [1]. These plasmas have high electron temperature and low gas temperature so non-equilibrium behavior of a large number of species becomes important [2]. Current computer resources allow studies of complex global models [3] which describe the behavior of such plasmas by taking into account a very large number of particles. The knowledge of ion-neutral reactions is generally accessible [4] although effects of reactions on transport parameters of particular ions are much less studied due to inability of instrumentation to detect rapidly vanishing ionic fluxes. This especially holds for ions whose transport is affected by fast reactions [5, 6].

Transport of Ar^+ plays significant role in various etching and deposition processes [7,8], in dark matter detection [9] and many more applications. It is known that transport parameters of Ar^+ in Ar are affected by resonant charge transfer reactions [10] leaving slow ions as a result. Charge transfer reactions are also a main collisional events in BF_3 gas where they introduce neutralization of Ar^+ ions [11]. The large rate coefficient for exothermic reactions (recombination energy of the ion is higher than the ionization potential of the gas particles) limits number of ions necessary to determine ion mobility. Boron dopant penetration in silicon is technologically achieved by DC pulsed plasma system (PLAD) most widely applying BF_3 gas [12, 13]. Uniform plasma and implantation with normal ion incidence are the main goals in this technological process. By using technique of Monte Carlo simulations one may calculate transport parameters for the cases that are out of the reach of experimental efforts provided complete cross section set is known. Reduced mobility data of both flux and bulk values as a function of *E/N*, are expected to be significantly affected by the presence of endothermic and exothermic reactions in the case of Ar^+ transport in the Ar/BF_3 mixtures.

II. CROSS SECTION SETS

A complete cross section sets for ion transport is scarce in spite of a broad range of specific methods relevant for quantification of particular cross sections. The main problem in heavy particle scattering, easily and precisely selecting the state of the projectile and target before the collision, is still very complicated for range of conditions, so databases for ion scattering [13, 4] are still devoid of such data. Phelps established the first worldwide accessible database with cross section sets [14] tested for each particular case either for swarm conditions of spatially resolved measurements of emission or ion mobility values. Another range of cross section sets was established by measurements of ionic transport coefficients [4] and this work is ongoing. In all cases only the most important cross sections may be established from the transport data. In the following section we will establish a complete cross section set for Ar^+ scattering on Ar and BF_3 from 0.1 meV to 1000 eV which will be used to calculate transport properties. Generally one may distinguish three characteristic energy ranges: the low energy regime where polarization scattering is dominant, the medium energy regime where polarization scattering is gradually replaced by hard sphere repulsion, and the high energy approximation regime.

Extensive discussion about transport properties of Ar^+ ions scattering in BF_3 gas applied to plasma physics problems was presented by Phelps [15] and Petrović and Stojanović [16]. Analytical expressions were offered in [11] to express apparently isotropic and anisotropic components of the cross section set (see Fig. 1). In order to focus on effects of reactive processes introduced by BF_3 we neglected all but these two components of the Ar^+ + Ar cross section set.

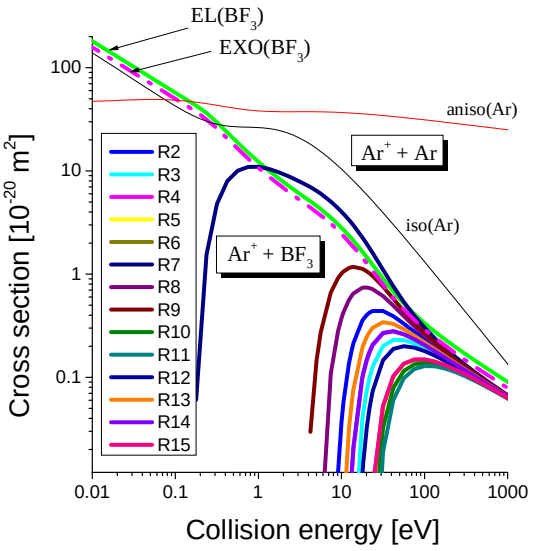

Fig.1. Cross sections for Ar^+ in BF_3 gas.

No	Reactions	Products	Threshold (eV)
1	EL	$Ar^+ + BF_3$ (el)	0.0000
2	R2	$Ar^+ + BF_2 + F$	7.4373
3	R3	$Ar^+ + BF + 2F$	12.2940
4	R4	$Ar^+ + BF + F2$	10.6461
5	R5	$Ar^+ + B + 3F$	20.1367
6	R6	$Ar^+ + B + F + F_2$	18.4889
7	R7	$BF_2+ + Ar + F$	0.1544
8	R8	$BF^+ + 2F + Ar$	5.0115
9	R9	$BF^+ + F_2 + Ar$	3.3637
10	R10	$F^+ + B + F_2 + Ar$	20.1488
11	R11	$F^+ + B + 2F + Ar$	21.7966
12	R12	$F^+ + BF + F + Ar$	13.9539
13	R13	$F^+ + BF_2 + Ar$	9.0972
14	R14	$F_2^+ + BF + Ar$	10.5846
15	R15	$F_2^+ + B + F + Ar$	18.4273
16	EXO	$BF_3^+ + Ar$	-0.2125

Table 1. Reaction products and thermodynamic thresholds for Ar+ + BF_3.

Complete cross section sets used in this work are shown in Fig. 1.

In this paper there are 15 endothermic and one exothermic processes. Therefore we have assumed in this work that exothermic processes are non-resonant, and neglected their effect on transport properties.

III. TRANSPORT PARAMETERS

Transport properties of species in gas plasmas are of great importance in understanding the nature of molecular and ionic interactions in gas mixtures [17, 18]. These properties include the mean energy, drift velocity, diffusion coefficients, ionization and chemical reaction coefficients, chemical reaction coefficients for ions and rarely. A Monte Carlo simulation code appropriate to calculate transport parameters [16, 17] of Ar^+ ions in Ar/BF_3 mixtures at non-zero temperature [19] has been used. In Monte Carlo simulations exothermic reactive collisions are followed in a similar way as all non-conservative collisions i.e. the swarm particle dissappears from the ensemble after exothermic collisions. This results in changes of the swarm particle number in the entire energy range introducing nonconserve effects in kinetic equations and thus division of transport parameters to flux and bulk ones [17].

In Fig. 2 we show results for mean energy as a function of *E/N* (*E*- electric field and *N*-gas density). Significant reduction and uniform control of mean energy of Ar^+ is obtained for argon content below 90 %. For Ar content below 10 % largest variations of mean energy are obtained for *E/N*>100 Td (1Td=10^{-21}Vm^2). These variations are the consequence of a reduced momentum transfer cross section for Ar^+ scattering with BF_3 (see Fig. 1) as compared to the scattering with Ar. At a high content of Ar charge transfer collisions dominate and make variation of mean energy with Ar content more uniform. Note, that for transport coefficients of Ar^+ in pure Ar one may find benchmark data presented in tabular form by Ristivojević and Petrović [19]. In Fig.3 we show the characteristic energies (diffusion coefficient normalized to mobility eD/K in units of eV) based on transversal (D_T) diffusion coefficients. Bulk and flux values of the characteristic energies are well matched.

In Fig. 4 variations of reduced mobility as a function of *E/N* are shown. The mobility *K* of an ion is a quantity defined as the velocity attained by an ion moving through a gas under the unit electric field. One often exploits the reduced or standard mobility defined as:

$$K_0 = \frac{v_d}{N_0 E} N \,, \qquad (1)$$

where v_d is the drift velocity of the ion, *N* is the gas density at elevated temperature *T*, N_0= $2.69\cdot10^{25}$ m^{-3} and *E* is the electric field. Behaviour of reduced mobility significantly changed with *E/N* with small additions of Ar, up to about 10 %. Especially intriguing are variations of flux reduced mobility which points to particle flux variations of Ar^+ ions as a function of their mean energy. On one side, small additions of Ar cause significant variations of particle flux at *E/N* close to 200 Td and on the other in that region we obtain significant difference of the flux and bulk drift velocities due to the BF_3 reactive processes [see also 10] which also significantly reduce Ar^+ density in favour of fast Ar [11]. Control of fast Ar flux at the surface thus can be easily achieved by small variations of Ar contents in Ar/BF_3 mixture. Due to reactive collisions bulk and flux values of reduced mobility are separated.

Longitudinal diffusion coefficients for Ar^+ ions in Ar/BF_3 mixtures as a function of *E/N* are shown in Fig. 5. Note that the difference between the flux and bulk values of diffusion coefficients, which have the same origin, have the same initial value as drift velocities. There are no published experimental data for the longitudinal and transverse diffusion coefficients of Ar^+ in Ar/BF_3.

IV. CONCLUSION

Data for swarm parameters for ions are needed for hybrid and fluid codes and the current focus on liquids or liquids in the mixtures with rare gases dictates the need to produce data compatible with those models. In this paper we show transport parameters for the Ar^+ in Ar/BF_3 mixtures which do not exist in the literature. In addition to presenting the data we show here the effects of non-conservative collisions to ion transport. Due to exothermic cross sections that are dominant at low energies, for small abundances of Ar (<10 %) exothermic process may be larger than the elastic scattering cross section.

The Monte Carlo technique was applied to carry out calculations of the mean energy, reduced mobility, diffusion coefficients as a function of reduced DC electric field. The results are believed to be a good base for modeling, which could be further improved when measured values of transport coefficients become available and then we could perform this analysis again.

Synthesis and characterization of Ti_3C_2 MXene film

Ivan Pešić, Daniel Mijailović, Vukašin Ugrinović, Miodrag Mitrić, Petar Uskoković, Vesna Radojević

***Abstract* — Two-dimensional (2D) transition metal carbides are known as MXenes can offer large surface area, excellent electrical conductivity and chemical stability. MXenes have shown great potential in a broad spectrum of applications such as photothermal cancer therapy, antibacterial effect, the improved electrical conductivity of polymers, hydrogen evolution reaction, energy storage, etc. Herein we report a successful synthesis and characterization of Ti_3C_2 MXene material. Properties of the material are tracked via scanning electron microscopy (SEM), X-ray diffraction (XRD), cyclic voltammetry (CV) and galvanostatic charge/discharge (GCD) experiments. SEM and XRD analysis revealed delaminated MXene structure, while XRD patterns also showed the presence of Mxenes structure, CV and GCD showed as electrode material for aqueous supercapacitors.**

***Index Terms* — Nanomaterials; MXenes; Ti_3C_2; Supercapactitor**

I. Introduction

The last few decades, the exponential development of technology reveals a large number of novel materials with specific physical and mechanical properties. MXenes represent class of 2D materials with the structure, analogue to graphene, *i.e.* 2D monolayers with very weak bonds between the layers They cover carbides and nitrides of transition metals with a unique combination of properties: excellent electrical conductivity, good mechanical properties, high thermal conductivity, large specific surface area and high resistance to thermal shock [1]. Not long after the discovery of the graphene [2], more materials could be found that can be classified as 2D materials. MXenes are the tertiary layered structure of carbide or nitrides of transition metals (most often from the third and fourth groups of the periodic table of elements). So far, more than 70 possible structures have been presumed, but only some have been successfully synthesized. Due to the synthesis process itself, the structure of surface is enriched with certain ions (depending on the synthesis method) such as (F^-, OH^- and / or O^-) which significantly affect the properties of the obtained MXens [3].

Typical commercial batteries require prolonged charging and therefore are limiting mobility of users. Pseudocapacitors show excellent ability to store a large amount of energy per unit mass.They are a sub-class of supercapacitors that are differentiated from electrical double-layer capacitors on the basis of charge storage mechanism store charge via formation of the electrical double layer at the electrode/electrolyte interface and, naturally, their capacitance is proportional to the electrode's specific surface area available for electrosorption of ions [4]. MXenes have the outstanding electrochemical performances which makes them perfect candidates for energy storage applications because: a conductive inner transition metal carbide layer enables fast electron supply to electrochemically active sites.

II. Experimental section

1 g of Ti_3AlC_2 MAX phase is etched with HCl/LiF method [4,5]. 10 ml of concentrated hydrochloric acid (HCl) was mixed with 1g of LiF in teflon vial under magnetic stirring. After a few seconds, the 1 g of Ti_3AlC_2 MAX phase is added in portions. After 24h on a magnetic stirrer on 35 °C, the mixture is poured in the centrifuge tube and teflon vial is washed with deionized water (DI) and added to the tube. The tube is filled to 45 ml and put onto centrifugation (3500 rpm during 90 sec.). After several washing procedures, the sediment is redispersed in DI water and put into the ultrasonic treatment for 1h in an inert atmosphere. The supernatant is collected and used for further experiments.

The concentration of obtained supernatant was determined via a simple mass difference method. A certain amount is poured into a small vial and then the mass is measured before and after drying. Concentration was 2.82 mg/ml.

A. Electrochemical measurements

40 µl of suspension of active material was drop cast on a glassy carbon (GC) electrode and left to dry under the lamp. After 2h, the commercial Nafion solution was dropped above the dried sample and left under the lamp overnight. All the measurements were performed on Gamry potentiostat in 1 M KOH aqueous solution with three electrode (3E) setup: reference (saturated calomel electrode, SCE), counter (Pt mesh) and the working electrode [5].

B. SEM

The rest of the supernatant is vacuum filtered on DURAPORE MEMBRANE FILTERS (0.22μm). After filtering overnight, we obtained thin "cake" of MXenes which is used for SEM. Small pieces were cut and put into SEM without sputtering.

C. XRD

The above mentioned 'cake' is also used for this examination. Small piece of the sample was cut and put into the device.

III. Results and Discusion

Fig 1. shows cyclic voltammetry (CV) profiles collected at various potential sweep rates *i.e.*, 5, 10, 50 and 100 mV s^{-1}.. Rectangular-like shape of CV curves indicates typical capacitive behaviour in the potential range from -0.8 to -0.2V vs. SCE. By decreasing the sweep rate, the voltammetric charge increased which is usual for electric double-layer capacitors (EDLC). [6-9]. Namely, this kind of sweep rate dependence is due to limited electrolyte accessibility of internal structure of Ti_3C_2.

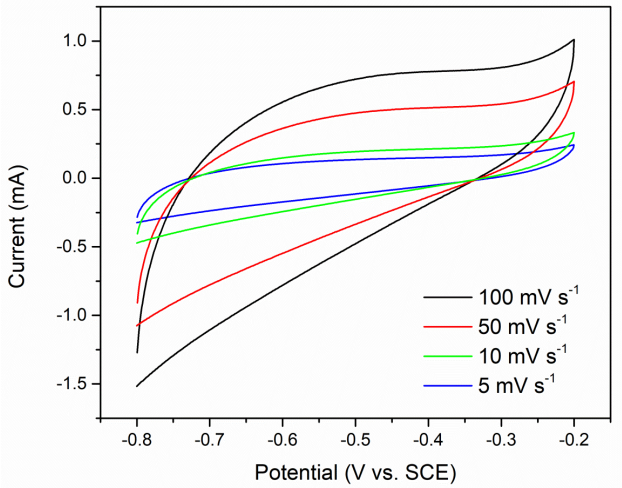

Fig. 1 - Electrochemical performance of $Ti_3C_2T_x$ MXene in 1M KOH electrolyte at different scanning speeds

The galvanostatic charge/discharge (GCD) curves at various current densities, *i.e.* 1, 5 and 10 Ag^{-1}, are shown in Fig. 2. It can be seen nearly triangular shape which is additional indicator of capacitive behavior.

Table 1 shows specific capacitance values of the sample at calculated from CV and GCD experiments.

TABLE I
SPECIFIC CAPACITANCES AT 5, 10, 50 AND 100 MVs^{-1}

ν (mVs^{-1})	C_s (Fg^{-1})
5	190.67
10	136.66
50	61.26
100	44.96

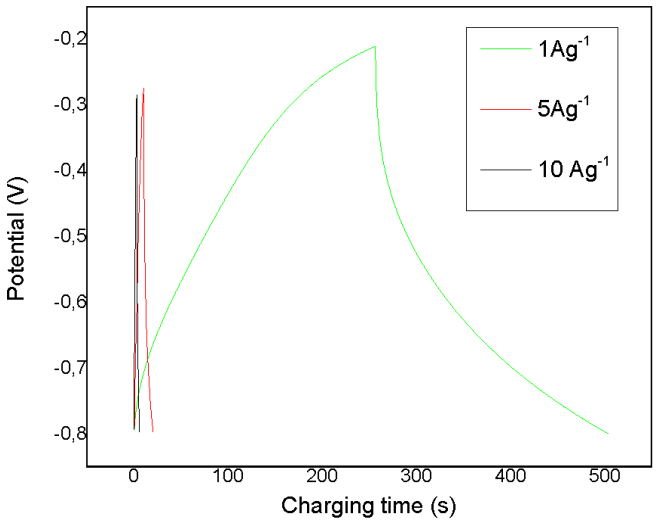

Fig. 2. Galvanostatic charge/dischagre diagrams at three different current densities. 2a - 1Ag^{-1}, 2b - 5Ag^{-1}, 10Ag^{-1}

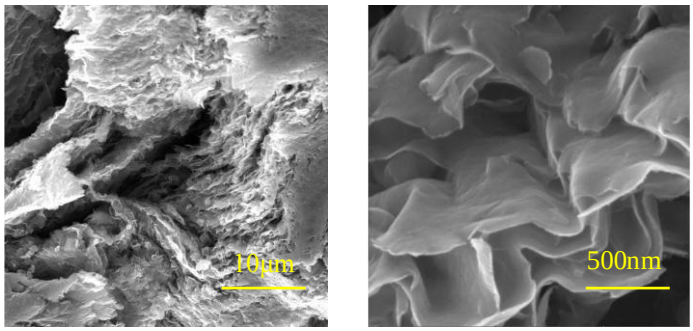

1a 1b

Fig. 3 - SEM photographs of the sample: 1a 5000x magnification, 1b 100000x magnification

The Fig 3. shows SEM photographs of our sample. On photograph 1a the lamellar structure can be spotted. It can be seen that sheets of MXene are stacked but not 'melted'. Also, they are not completely flat, but that can be a good characteristic of the supercapacitve performance [10]. This phenomenon is more noticeable at photograph 1b (greater magnification). Interlayer space and sheets itself are more clearly visible.

On Fig 4, sharp peak at approximately 7º (corresponds to 002 diffraction) confirmes the interlayered distance between sheets of MXene [11-13]. Also, it can be noticed that 'main' peak (~7º) is significantly smaller after 1 day of aging. It loses intensity in time but the main drop is after the first day [14]. This loss of intensity can be interpretated as degradation of structure probably due to formation of TiO_2. The peak at 14 corresponds to 004 plane and it is almost completely lost after 2 days. This reveals one big disadvantage of MXenes and that is relatively fast degradation of the structure.

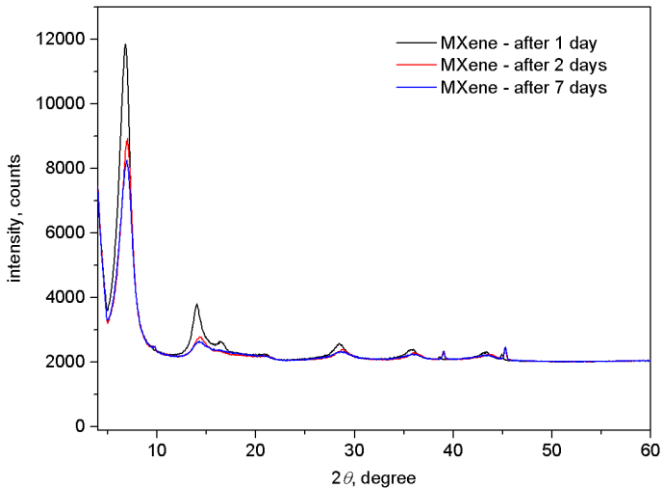

Fig. 4 - Three XRD patterns of our sample collected at different aging period: Black- after 1 day, Red after 2 days and Blue after 7 days

IV. Conclusion

Herein we report a successful synthesis of Ti_3C_2 MXene. XRD results clearly indicate MXene structure, SEM photographs show delaminated structure which is crucial for supercapacitive performance. Rectangular like shape also shows that our sample have capacitive properties. This specific combination of the synthesis and characterization of this material contributes to a better understanding of the process of obtaining MXenes, which are increasingly used to produce nanocomposites with very specific properties. Composites can be with a polymer matrix (PVA, PMMA, PE, PVDA ...) and can also be combined with ceramic and/or metal nanotubes (Active Carbon, Si, S, Pt ...)

Soft polymeric networks based on poly(methacrylic acid),itaconic acid, casein and liposomes for targeted delivery and controlled release of poorly water-soluble active substance

Maja Marković, Vesna Panić, Sanja Šešlija, Pavle Spasojević, Vukašin Ugrinović, Nevenka Bošković-Vragolović and Rada Pjanović

***Abstract*—Soft polymeric networks based on poly(methacrylic acid) (PMAA) are attractive candidates for targeted and controlled drug release due to their non-toxicity, biocompatibility and pH-sensitivity. The highly hydrophilic nature of PMAA networks enables transport of hydrophilic drugs only. This limitation has been overcome in present work by a PMAA modification with casein and liposomes. Casein is a natural amphiphilic protein which enabled the encapsulation and targeted and controlled release of the model drug- caffeine. The FTIR spectra showed that the hydrophobic interactions and hydrogen bonds were established between the casein and caffeine. The caffeine *in vitro* release was monitored in two media at 37°C: phosphate buffer pH=6.8, which simulated the pH environment in the human intestines and 0.1M HCl pH=1.2, which simulated the pH environment in the human stomach. The presence of liposomes with the encapsulated caffeine in the carriers caused the decrease in the speed of caffeine release. Introduction of itaconic acid (IA) as a hydrophilic and pH-sensitive substance with two carboxylic groups resulted in a non-regular structure of the carriers with large voids which caused an increase in swelling rate of the carriers and an increase in speed of caffeine release. All obtained results showed that the targeted and controlled release of a poorly water-soluble substance was achieved.**

I. Introduction

DRUG delivery carriers for the targeted delivery of the active substances and their controlled release are intensively developed and used in treatment of some serious diseases [1]. pH sensitive soft polymeric networks- hydrogels have a great potential in this field of application because they respond to the pH changes in the external medium by swelling or contracting due to which they release their loadings. pH sensitive hydrogels of much interest for targeted drug delivery are based on poly(methacrylic acid) (PMAA). These hydrogels are biocompatible, non-toxic and contain a large number of ionisable –COOH groups. Ionization of carboxylic groups and generation of the negative charges on them occurs if the pH of the external medium is above the pKa of PMAA (4.6) causing the repulsion of the PMAA polymeric chains and swelling of the PMAA [2]. Although PMAA hydrogels have been shown to be good carriers of a hydrophilic active substance, the limitation for the use of these carriers in controlled release of the poorly water-soluble active substances is imposed by the hydrophilic nature of PMAA and relates to the poor interactions with a poorly water-soluble active substance [3]. In order to overcome this limitation PMAA hydrogels must be modified with amphiphilic substances such as some proteins and phospholipidic nanoparticles. Casein (the major milk protein) is a great candidate for targeted delivery of poorly water-soluble active substances due to its amphiphilic nature, pH sensitivity, non-toxicity and biocompatibility. It is also recognized as a GRAS protein and approved by American Food and Drug Administration. Spherical phospholipidic nanoparticles, such as liposomes which consist of one or more lipidic layers and an aqueous core, could be used for delivery and controlled release of both, hydrophilic and poorly water-soluble substances.

The goal of this research was to develop a hydrophilic polymer carrier for targeted delivery and controlled release of a poorly water-soluble substance. Hence, carriers for poorly water-soluble model drug-caffeine based on poly(methacrylic acid) and casein (PMAC), PMAC with itaconic acid (PMAC/IA) and PMAC with incorporated liposomes(PMAC-L) were synthesized. The successful entrapment of a drug, its

delivery to a specific place in the human body and the controlled release depend on a successful design of a carrier. Therefore, an investigation of the structure of synthesized carriers and of interactions established between the carrier and the drug was conducted. In addition, the influences of the presence of the itaconic acid and the presence of the liposomes on the caffeine release and on the swelling rate of the carriers were also analyzed. In order to control the drug release and to release a desirable concentration of a drug in the specific place in the human body it is important to get an insight into the drug release kinetic, hence two mathematical models were used for the investigation of caffeine release kinetic.

II. Materials and Methods

A. Materials

Methacrylic acid (MAA) (99.5%) was purchased from Merck, Germany. Sodium caseinate (C) powder, containing 88.9 wt. % of protein (the rest was the proteins, lipids, attached moisture and ashes) was supplied from Lactoprot, Deutchland GmbH (Germany). Itaconic acid (IA) (≥99%) was supplied from Aldrich Chemical Co. (USA). NATIPIDE® II containing phospholipids from soybean >20% (with 3-sn-phosphatidylcholine 76+ 3%) was purchased from Lipoid (Germany). Caffeine (Cf) was supplied from Merck (Germany). N, N'-Methylenebisacrylamide (MBA) (p.a.) and sodium hydroxide (p.a.) (NaOH) were supplied from Aldrich Chemical Co. (USA). The initiator, 2,2'-azobis-[2-(2-imidazolin-2-yl)propane] dihydrochloride (VA-044) (99.8%) was purchased from Wako Pure Chemical Industries (Japan). Monobasic sodium phosphate (anhydrous) (NaH_2PO4) and dibasic sodium phosphate (anhydrous) (Na_2HPO4) were purchased from Centrohem (Serbia). Hydrochloric acid (37%) was supplied from Zorka Pharma (Serbia). All chemicals were used as received.

B. Preparation of the samples

The PMAC and PMAC/L carriers were obtained via the free-radical polymerization mechanism using the procedure previously described by M. Markovic et al [4]. The PMAC samples were obtained as follow. Firstly, 4 cm^3 of MAA and caffeine were dissolved into an adequate amount of distilled water (Table 1.). For the PMAC samples with itaconic acid had different only the first step of the synthesis was different: 3 cm^3 of MAA, 1 cm^3 of itaconic acid and caffeine were dissolved into an adequate amount of distilled water (Table 1.). Then, after the total neutralization of MAA (or MAA and IA) with NaOH, the mixture was heated to 60°C and 4 g of casein was added and dissolved. Thereafter, crosslinker MBA (Table 1.) was added and after 10 minutes the initiator VA-044 (0.9cm^3 of 1wt% aqueous solution) was added and the polymerization process began immediately. The mixture was poured quickly into the glass moulds (plates 12 cm × 12 cm, separated by a 2 mm tick PVC hose) and left in the air oven at 60°C for 5h. After the polymerization process ended, the disc-shaped samples (7mm in diameter) were cut and dried at room temperature. All obtained samples were stored in an exicator until they were used for further investigation.

The synthesis path of the PMAC/L samples was similar to the synthesis path of the PMAC samples, but the synthesis was carried out at 40°C in order to prevent liposomes degradation. The first step was the addition of the liposomes with the encapsulated caffeine in a drop wise manner to 4 cm^3 of MAA or to 3 cm^3 of MAA and 1 cm^3 of IA in synthesis of the sample with itaconic acid. After total neutralization of MAA (or MAA and IA) with NaOH, the mixture was heated to 40°C and 4 g of casein was added and dissolved. The crosslinker and initiator were added in the same manner as previously. The liposomes with encapsulated caffeine were obtained by pro-liposomic method [5]. The caffeine solution in distilled water (20 mg/ml) was added to NATIPIDE® II (10wt% with respect to the final liposomic dispersion) in a drop wise manner under the constant stirring.

The synthesized samples were denoted as PMAC-xN-y, PMAC-xN-L, PMAC/IA-xN-y and PMAC/IA-xN-L,where N represented the symbol for neutralization, L was the symbol for liposomes, x denoted the neutralization degree of MAA and y denoted the caffeine amount in the carriers (g).

TABLE 1.
FEED COMPOSITION

Samples	H_20 (cm^3)	Caffeine (g)	Liposomes with caffeine (cm^3)
PMAC-100N-0.2	6.20	0.2	-
PMAC/IA-100N-0.2	6.00	0.2	-
PMAC-100N-L	3.10	-	3.10
PMAC/IA-100N-L	3.00	-	3.00

C. Fourier Transform Infrared Spectroscopy (FTIR) and Scanning Electron Microscopy (SEM)

The FT-IR spectra of xerogel disks were recorded in transmittance mode for the wavelength range of 600–4000 cm^{-1} with a resolution of 4 cm^{-1}, using Nicolet™ iS10 FTIR Spectrometer. The SEM analyses were performed using a Tescan MIRA 3 XMU field-emission gun scanning electron microscope (FEG-SEM) with an acceleration voltage of 20 kV.

D. Monitoring of the carriers swelling and caffeine release

Swelling and caffeine release measurements were carried out at 37°C in two media during a 24h period: 0.2 M phosphate buffer (pH=6.8) (PB) (as a simulation of duodenum pH environment) and 0.1 M solution of HCl (as a simulation

of stomach pH environment) [6]. Dry hydrogel disks with known initial weight (m_0) were entirely immersed in the specified solution and left to swell. At predetermined time intervals the disks were removed from solutions and weighed (m_t). This was repeated until the equilibrium was reached (m_{eq}). Swelling degree (SD) at the equilibrium state (SD_{eq}) was calculated as:

$$SD_{eq} = \frac{(m_{eq} - m_0)}{m_0}. \quad (1)$$

The absorbances of the caffeine solutions in release experiments were measured at predefined time intervals at 273 nm using the UV-Vis Shimadzu UV-1800 spectrophotometer. The caffeine release kinetics was investigated by the Kopcha model (2), which involves both diffusion and polymer chains relaxation effects on the drug release [7]:

$$\alpha = \frac{M_t}{M_\infty} = k_D t^{0.5} + k_R t^1, \quad (2)$$

Where α represents the fractional drug release, M_t is the released concentration of drug at time t, M_∞ is the released drug concentration at equilibrium, k_D is the constant of the speed of drug diffusion and k_R is the constant of the speed of drug release by the process of the polymer chains relaxation.

III. Main Results

The FTIR spectra of the synthesized PMAC carriers are presented in Fig. 1. and they have all characteristic peaks of poly(methacrylic acid) and casein.

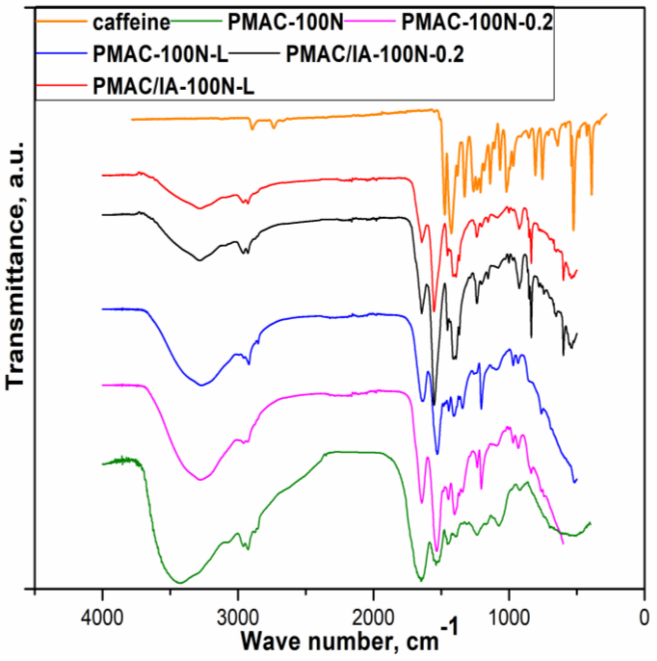

Fig. 1. The FTIR spectra of caffeine and of the PMAC carriers of different formulation

The FTIR spectrum of the PMAC samples without the caffeine was described in our previous work [4]. Compared to the FTIR spectrum of the PMAC carriers without the itaconic acid the FTIR spectrum of PMAC/IA carriers has more intensive peaks at 1540 cm^{-1} (symmetric stretching vibration of C(=O)–O^-) and at 1645 cm^{-1} (C(=O)–OH symmetric stretching vibrations) as a consequence of the presence of the higher number of the –COO^- and –COOH groups due to the presence of two carboxylic groups in the itaconic acid structure [8]. The presence of the caffeine was confirmed by the presence of the caffeine characteristic peaks: the peak at 973cm^{-1} (C-C stretching), 1357 cm^{-1} (C-H stretching) and at 1700 cm^{-1}(stretching of C=O) [9]. The shifts of the characteristic peaks of casein at 1235 cm^{-1} (saturated C–C stretching) and at 1452 cm^{-1} (C-C stretching of aromatic ring) to 1245 cm^{-1} and to 1442 cm^{-1}, respectively, suggested that hydrophobic interactions between the casein and caffeine were established [10]. Also, the shift of the characteristic peak of casein at 1398 cm^{-1} (C=O stretching of aspartic acid and glutamic acid residues) to 1408 cm^{-1} could be caused by the hydrogen bonds established between the casein and caffeine [10]. The FTIR spectra of the PMAC-100N-L and PMAC/IA-100N-L showed the shift of the characteristic peak of casein observed at 1398 cm^{-1} to 1388 cm^{-1} which could be caused by the hydrogen bonds established between the casein and the liposomes (carbonyl group or N-H group of amide II of protein and oxygen group of phospholipid nanoparticles). The hydrophobic bonds established between the casein and liposomes may cause the shifts of the casein characteristic peaks at 1235 cm^{-1} and at 1452 cm^{-1} to 1245cm^{-1} and to 1444cm^{-1}, respectively.

The SEM micrographs of synthesized PMAC carriers are presented in Fig. 2. The micrograph of PMAC-100N-0.2 (Fig. 2. a)) showed the regular porous structure. The PMAC-100N-L sample has the same structure as the PMAC-100N-0.2 and the micrograph confirmed the presence of the liposomes which were marked with the white circles (Fig. 2. b)). The micrograph of the PMAC/IA-100N-0.2 (Fig. 2. c)) showed a non-regular highly porous structure. This was expected due to the presence of the itaconic acid which caused higher value of swelling degree and higher swelling rate of the carrier compared to the samples without itaconic acid. The micrograph of the PMAC/IA-100N-L (Fig. 2. d)) showed the same structure as the analog sample without the liposomes. The liposomes are marked with white circles in Fig. 2. d).

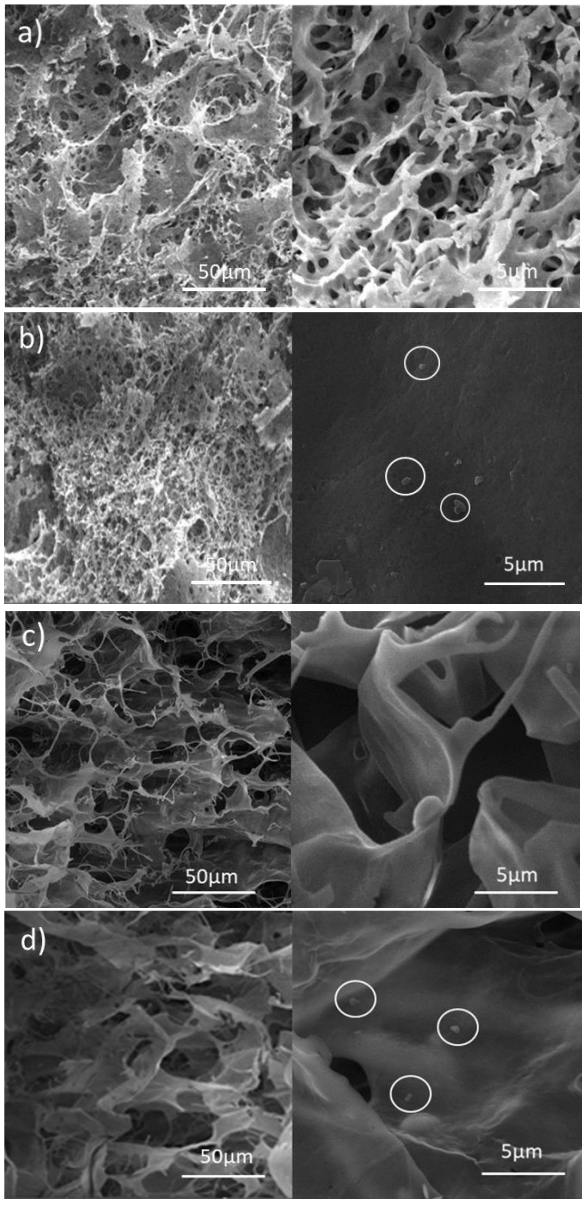

Fig. 2. The SEM micrographs of the carriers of the different formulation

The swelling curves of the synthesized carriers and caffeine release profiles in two media with different pH values are presented in Fig. 3. and in Fig. 4., respectively. From Fig. 3, it can be seen that the PMAC carriers with itaconic acid have higher equilibrium swelling degree and higher swelling rate than the analog samples without the itaconic acid (Table 2.) due to the presence of the higher number of carboxilyc groups. The values of the equilibrium swelling degree were higher in PB than in 0.1 M HCl for all samples (Table 2.) because the negative charges were generated on the carboxylic groups in PB medium which caused the repulsion between the polymer chains and the higher swelling rate of all carriers than the swelling rate of the carriers in 0.1M HCl. The presence of the liposomes in the carriers caused the decrease in the value of the swelling degree. The diffusion of the medium into the carriers could be slower due to the presence of the liposomes in the pores of the matrix of the carriers.

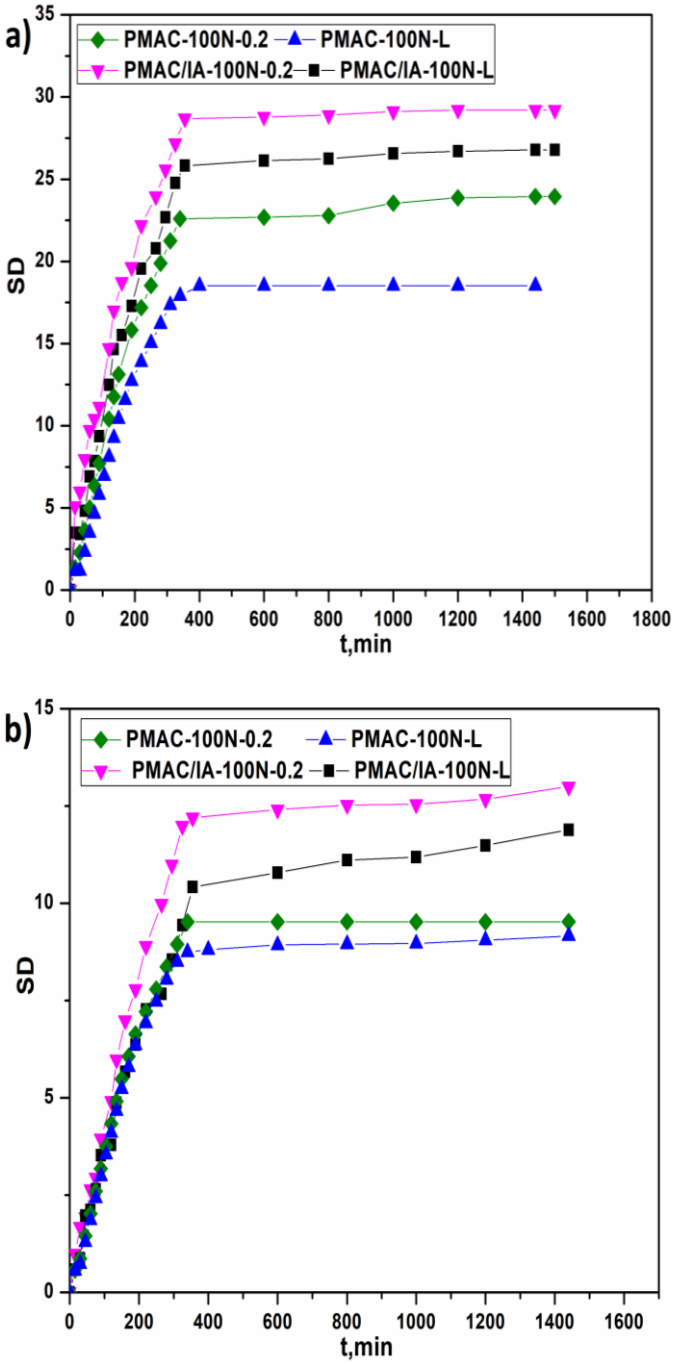

Fig. 3. The swelling curves of the carriers for: a) PB and b) 0.1 M HCl

The released caffeine concentration- c (mg/ml) during time- t (Fig. 4.) showed that the carriers with itaconic acid released caffeine faster than the carriers without it due to the presence of the higher number of carboxylic groups and higher swelling rate. All samples released higher concentration of caffeine in PB than in 0.1M HCl due to the aforementioned behavior of the samples in the PB medium. The caffeine was released more slowly from the samples with liposomes than from the samples without liposomes.

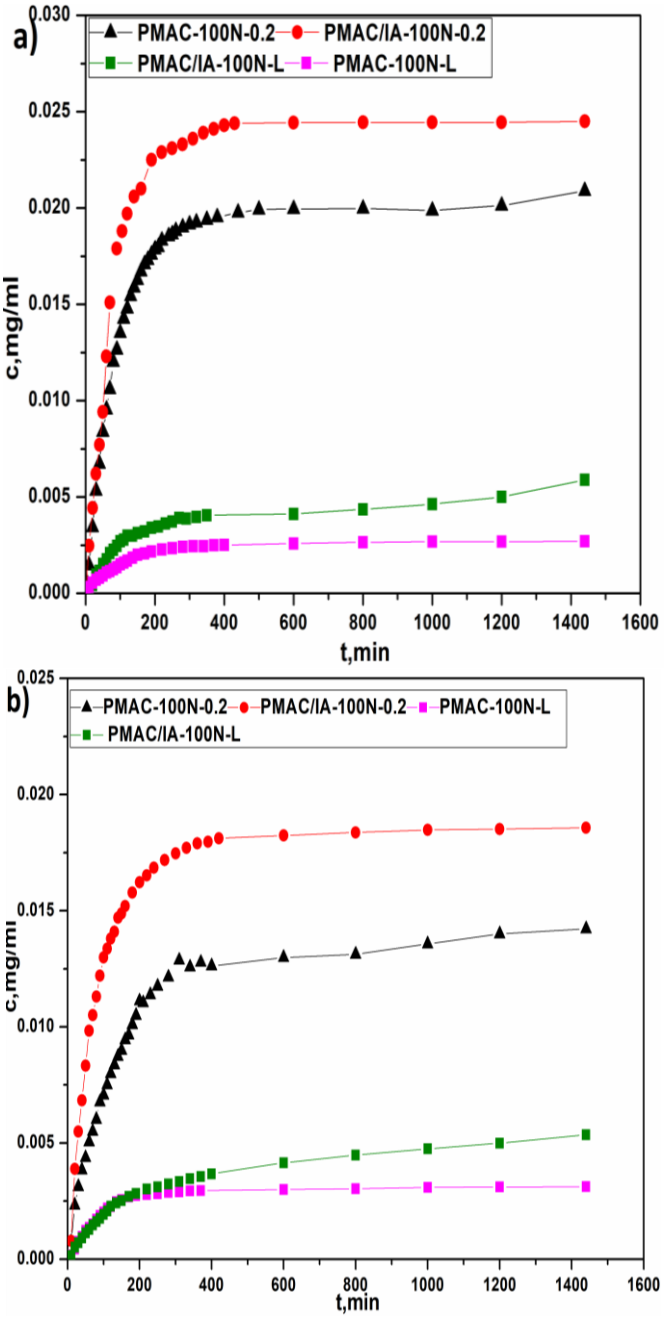

Fig. 4. The caffeine release profiles from the carriers in: a) PB and b) 0.1 M HCl

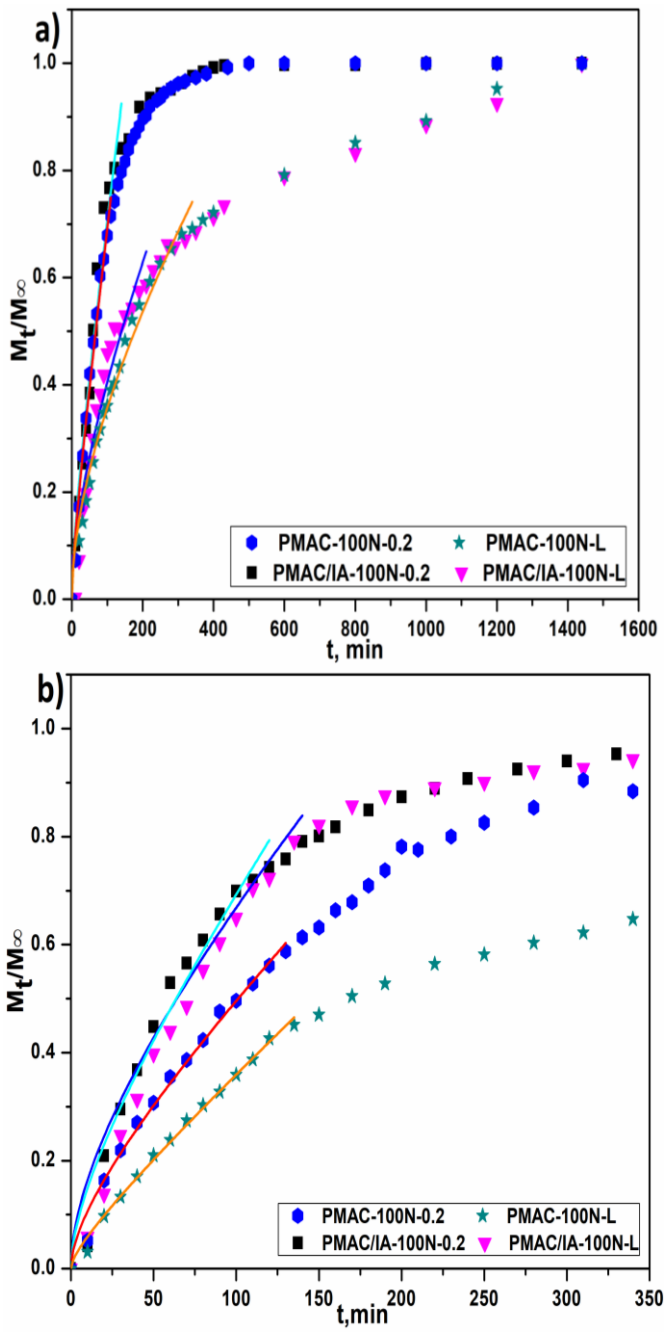

Fig. 5. The fractional caffeine release from the carriers in both media: the symbols represent the experimental data and the solid lines represent the Kopcha model

The fractional release data for PB and 0.1 M HCl to which the Kopcha model was applied is presented in Fig. 5. a) and b), respectively. The estimated values of the parameters of the Kopcha model, the field of applicability $\Delta\alpha$ and the values of R^2 are shown in Table 2. The first 60%-80% of release data fitted well to this model (R^2 ~0.980). The values of the Kopcha model parameter k_D were higher than the values of k_R for all samples, which suggested that the diffusion was the main mechanism of caffeine transport into the media.

TABLE 2.
THE VALUES OF THE EQUILIBRIUM SWELLING DEGREE AND THE KINETIC PARAMETERS OF THE KOPCHA MODEL

Sample	Media	The Kopcha model				SDeq
		k_D $*10^2$	k_R $*10^3$	Δα %	R^2	
PMAC-100N-0.2	HCl	2.62	2.34	58.78	0.991	9.5
	PB	2.40	4.52	71.53	0.989	23.95
PMAC/IA-100N-0.2	HCl	3.67	3.26	74.28	0.972	13.0
	PB	2.96	4.1	84.08	0.968	29.2
PMAC-100N-L	HCl	3.22	0.380	70.74	0.983	9.2
	PB	3.65	2.46	74.96	0.998	22.6
PMAC/IA-100N-L	HCl	2.65	3.65	79.24	0.986	11.9
	PB	3.09	0.96	57.53	0.939	26.8

IV. CONCLUSION

The PMAA based carriers of different formulations were synthesized for controlled and targeted delivery of a poorly water-soluble model drug-caffeine. The significance of these carriers is that they represent the fusion of hydrophilic polymers-PMAA and IA and one amphiphilic polymer-casein, which enabled bonding to poorly water-soluble substance. The FTIR spectra of these carriers showed that established interactions between the casein and caffeine were hydrophobic interactions and hydrogen bonds. The SEM micrographs showed the regular porous structure of the PMAC carriers without itaconic acid, whereas the PMAC carriers with itaconic acid had a non-regular structure with large voids. The presence of the liposomes in the carriers was confirmed by the SEM micrographs of the PMAC-L carriers, indicating that the degradation of the liposomes did not occur during the synthesis of the carriers.

The carriers with itaconic acid had higher equilibrium swelling degree and higher swelling rate than the samples without it. The presence of the liposomes caused a minor decrease in the values of the SDeq, which could be a consequence of the physical presence of the liposomes in the pores of the carriers which may cause the decrease in the diffusion speed of the media into the carriers. All carriers had higher swelling rate in the PB than in 0.1M HCl.

These pH sensitive drug delivery carriers were able to protect the model drug in 0.1M HCl at 37°C (as simulation of the pH condition in human stomach) and release higher caffeine concentration in a medium which simulated the conditions in human intestines- phosphate buffer pH=6.8 at 37°C. The carriers with itaconic acid released higher caffeine amount than the analog carriers without it due to the higher swelling rates. The mathematical model used for investigation of the release kinetics- the Kopcha model, fitted well to the experimental caffeine release data. The Kopcha model showed that the diffusion governed caffeine release from all samples and that the polymer chains relaxation was also present, but its influence on caffeine release was minor. The best control of caffeine release was achieved from the PMAC samples with incorporated liposomes. Incorporated liposomes in PMAC carriers decreased the speed of the caffeine release compared to the samples without them. Synthesized pH-sensitive PMAC carriers are promising candidates for controlled and targeted delivery of poorly water-soluble drugs.

Swelling and bioactivity of poly (methacrylic acid)/ hydroxyapatite / bioactive glass composite hydrogels

Vukasin Ugrinovic, Vesna Panic, Sanja Seslija, Pavle Spasojevic, Ivanka Popovic, Djordje Janackovic, Djordje Veljovic

***Abstract*—The goal of the study was to examine the influence of bioactive glass (BG) particles incorporation on properties of poly(methacrylic acid)/hydroxyapatite (HA) composite hydrogels. Composite hydrogels were synthesized by free-radical polymerization. Theoretical amount of incorporated inorganic fillers was 60 wt%, while BG/HA ratio was varied. Composites were characterized by Scanning Electron Microscopy, and swelling behavior was determined in distilled water. During 28 days of in vitro bioactivity test, pH changes were constantly monitored. Equilibrium swelling increased by 110.9 % as the content of BG in composites increased. pH values of SBF were significantly higher in the case of the sample with higher amount of BG. Morphological investigations revealed localized bioactivity of the sample with 40 wt% of BG, while the one with 10 wt% exhibited no significant bioactivity.**

***Index Terms*—hydroxyapatite; scaffold; 45S5 bioactive glass; poly (methacrylic acid).**

I. Introduction

Bone tissue scaffolds are three-dimensional porous structures designed to, temporally or permanently, replace a critical bone tissue volume loss, and act as a structural support for adhesion, proliferation and differentiation of osteoblasts, which is the main precondition for healing and regeneration of damaged tissue. For the successful design of bone tissue scaffolds the following requirements have to be satisfied: biocompatibility, satisfactory mechanical properties, porosity and bioactivity [1], [2].

Composite hydrogels, the composites constituted of hydrogels - the three-dimensional, hydrophilic networks, and inorganic nano-filler particles such as hydroxyapatite (HA) and bioactive glass (BG), have gained increasing attention over the past few years due to their unique properties such us, high degree of swelling and improved mechanical properties compared to pure hydrogels [3]–[11].

For biomedical purposes, hydrophilic polymeric networks based on poly (methacrylic acid) (PMAA) have been mainly investigated as drug delivery vehicles due to pH-sensibility [12]–[14]. However, the possibility to easily change the volume in response to protonization/ deprotonization of carboxyl groups, allows simple tunability of PMAA hydrogels porosity [8].

HA is the main inorganic component of human bone tissue and accounts for ≈ 60 % of total bone mass. There have been numerous investigations of HA as the main component of bone tissue scaffolds. HA imparts stiffness and mechanical stability to scaffolds, as well as biocompatibility and osteoconductivity [15].

In our previous research we demonstrated significant improvement of PMAA hydrogels modulus by incorporation of nano-HA particles [8]. However, the lack of bioactivity could be the limiting factor in potential clinical application. Therefore, the aim of this study was further optimization of PMAA/HA scaffolds bioactivity by incorporation of 45S5 BG particles, which is well known, highly bioactive material [16].

II. The Method

Nano-sized HA powder was synthesized as in [17], [18]. Molar ratio of Ca/P was 1.67 which corresponds to stoichiometric HA.

Bioactive glass 45S5 was synthesized by melt-quenching method. Raw materials were mixed (Table 1), homogenized and subsequently melted by heating from room temperature to 1400 °C at 10 °C/min. After 1 h of maintaining BG at 1400° C, it was room-temperature water quenched and dried in an oven. To obtain fine particles, BG was ground in Planetary Ball Mill Retsch PM 100 (33 ±1 g of glass was ground for 1 h in 125 ml grinding jar, with 500 zirconium oxide balls 5 mm in diameter, under the wheel speed of 500 min^{-1}).

TABLE I
THE WEIGHTS OF COMPONENTS IN THE PRECURSOR MIXTURE FOR BIOGLASS SYNTHESIS

SiO_2 [g]	$CaCO_3$ [g]	$NaH_2PO_4 \cdot 2H_2O$ [g]	Na_2CO_3 [g]
17.03	15.28	4.61	13.08

PMAA/HA/BG composite hydrogels were synthesized by free-radical polymerization by the modification of already described procedure [8]. Briefly, 0.6972 g of sodium hydroxide was dissolved in 1.50 ml of distilled water after which 1.50 ml of methacrylic acid was added. In the next step, 0.0107 g of crosslinker (N,N′-methylenebisacrylamide) was added, followed by the addition of previously synthesized nano-HA and 45S5 bioglass powders (Table 2), to obtain the composites with the 60 wt% of inorganic phase. Finally, 100 µl of 6.8 % w/v initiator (2,2′-Azobis[2-(2-imidazolin-2-yl)propane] dihydrochloride) solution was added to the reaction mixture. After 20 minutes of vigorously stirring, and 15 minutes of sonication, the mixture was poured into glass molds, and placed in an oven at 70 °C, for 4 h to complete reaction.

Theoretical content of inorganic phase (with regard to polymeric network) in composites was fixed at 60 wt%, while the amounts of HA and 45S5 bioglass were varied to prepare the samples containing 10 and 40 wt% of bioglass.

The obtained samples are denoted as CHX, where X= 10 or 40, denoting the weight fraction of bioglass in the composites.

TABLE II
THEORETICAL CONTENT OF INORGANIC PHASE IN THE SYNTHESIZED COMPOSITE HYDROGELS

Sample	*HA [g]*	*45S5 bioglass [g]*
CH10	2.3542	0.4709
CH40	0.9417	1.8834

Dynamical swelling behavior of composites was determined as a function of time, in distilled water at room temperature (20°C), and calculated using the equation:

$$SD = \frac{m_t - m_0}{m_0} \quad (1)$$

Where *SD* is the swelling degree of the hydrogel at time *t*, m_t is the weight of the swollen hydrogel sample at time *t*, and m_0 is the weight of the xerogel.

The equilibrium swelling degree (SD_{eq}) is the swelling degree of the hydrogel at equilibrium, i.e. when the hydrogel sample attained constant mass after swelling (m_{eq}):

$$SD_{eq} = \frac{m_{eq} - m_0}{m_0} \quad (2)$$

For each sample at least three swelling measurements were performed and the mean values were used.

Morphological examinations of the obtained samples were carried out using Field emission scanning electron microscope (SEM) *Tescan MIRA 3 XMU* operating at 20 kV. Prior to examination, all samples were swollen to equilibrium in distilled water, lyophilized, and sputter-coated with gold using a *POLARON SC502 sputter coater* in order to avoid electrostatic charge. Prior to lyophilization samples were frozen for two days at -20° C, after which lyophilization was carried out using *Martin Christ Freeze-dryer Alpha 1-2 LDplus*, under the vacuum of 0,310 mbar and -32° C temperature, during 48 h.

In vitro bioactivity behavior was investigated by soaking composite hydrogels in simulated body fluid (SBF), prepared as in [19]. The experiment was carried by immersing the samples of ≈150 mg in 15 ml of SBF (concentration ≈ 10 g/l) for 28 days at the temperature of 37° C, while renewing the solution of SBF each three days. At the same time (before the each SBF solution renewing), the pH values of the solutions were measured by pH meter (*WTW inoLab 7110, Weilheim, Germany*).

III. RESULTS AND DISCUSSION

The influence of BG incorporation on the swelling behavior of composite hydrogels was examined in distilled water. Fig. 1 presents obtained swelling curves.

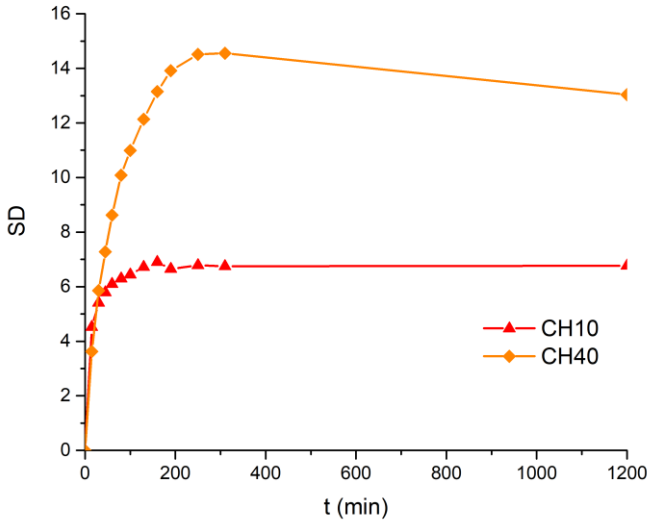

Fig. 1. Isothermal swelling curves of obtained composite hydrogels.

It can be noticed that increase in BG content increased SD_{eq} values by 110.9 %. Nano-sized particles of inorganic filers are characterized by large specific surface area and can act as a crosslinker through the interactions with polymer matrix. For example, Li has reported the formation of chelating and hydrogen bonds in polyacrylamide/HA composites between Ca^{2+} ions and C=O bonds and the PO_4^{3-} (in HA) and NH_2 (in polyacrylamide), respectively [10]. In our system, we can presume similar interactions: 1) chelating bonds between Ca^{2+} (in HA), and $–COO^-$ (in PMAA), and 2) hydrogen bonds between PO_4^{3-} (in HA) and –COOH (in PMAA). However,

since the precursor for polymer synthesis, methacrylic acid, is 100% neutralized by sodium hydroxide (-COO^- form prevails in the structure), probably, the majority of interactions will be chelating bonds. Therefore, the addition of BG instead of HA would decrease the content of crosslinker which in turn will cause the network to swell more. Also, HA nano-particles are smaller and have significantly higher specific surface than BG particles, which means that substitution of HA with BG would decrease the total surface area of filler, which will also lead to decreased crosslinking and increased swelling.

Noticeable deswelling of CH40 after 1200 min is also indicative of decreased crosslinking of CH40, as it is probably the consequence of partial dissolution of hydrogel network. On the other hand, CH10 demonstrated higher structural stability.

Fig. 2 plots the difference between the measured pH and the pH of the basic solution (ΔpH), versus time.

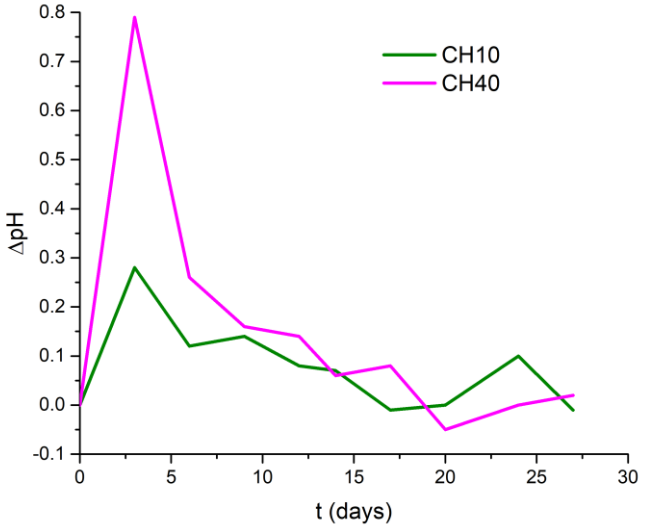

Fig. 2. pH difference between the measured pH and of the basic solution as a function of time.

The increase in pH value after first 3 days is significantly higher for CH40. The increase in the pH of SBF occurs as a result of the exchange of Ca^{2+} and Na^+ ions from glass, with H^+ ions from water, and is an indication of the glass dissolution. The similar trend is noticed after 6 days but with the significantly lower pH values, indicating the slowdown of the ion exchange reaction. Further experiments have demonstrated continuous decline of pH values suggesting the reducing of ion exchange activity. The pH values measurements have indicated the peak of the exchange after the first 3 days of immersion, while the majority of reaction is completed by 12 days. These results suggest higher bioactivity of CH40.

Fig. 3 shows SEM micrographs of lyophilized CH10 composites, after 28 days of immersion in SBF. Spherically agglomerated rod-like HA nano-particles, 50-100 nm in size, are uniformly distributed through PMAA network of composite. BG particles of different sizes are observable in the structure of composite hydrogel. However, there is no indication of significant surface coverage by newly-formed HA crystals, which is sign of bioactivity. SEM micrographs from our previous work evidenced good wetting of HA particles by PMAA matrix, which had a major influence on the inclusion of high amount of HA and uniform distribution of particles, hence allowing improvement of mechanical properties [8]. However, at the same time it limited the exposure of HA to SBF, thus preventing the bioactivity. PMAA is non-biodegradable polymer and thin layer of polymer over the bioactive particles could negatively affect the bioactivity of composites. From the Fig. 3B it is clearly visible that HA particles are coated by a thin layer of PMAA. Thus, substitution of 10 wt% of HA with BG particles didn't significantly affect the microstructure and thus no significant improvement of bioactivity has been achieved compared to PMAA/HA from [8].

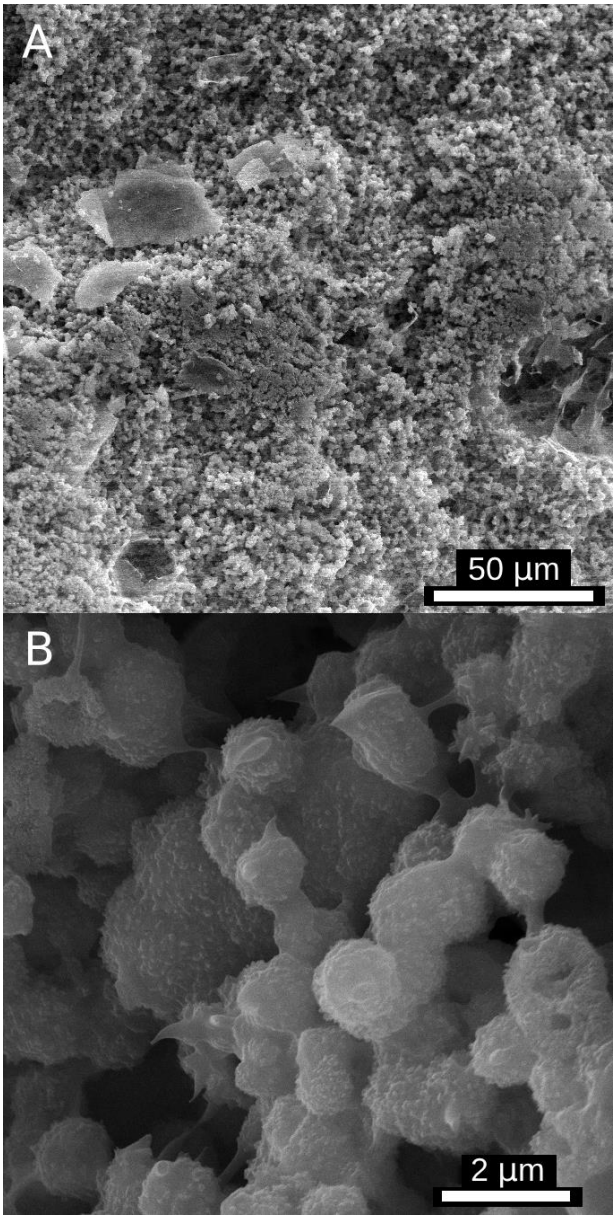

Fig. 3. SEM micrographs of lyophilized CH10 composite hydrogels after 28 days of in vitro bioactivity test. (A) 1000x magnification and (B) 20000x magnification.

On the other hand, Fig. 4 reveals a certain degree of bioactivity of CH40 composite hydrogels. There is no significant surface coverage by newly-formed HA, but localized bioactivity could be noticed, especially in the vicinity of BG particles. In the Fig. 4B is demonstrated a BG particle covered by a layer of HA. In the background of the particle, a thin coat of PMAA is noticeable, however it doesn't cover the particle itself, enabling unhindered contact between the particle and SBF. These results are in accordance with swelling results proving a lower degree of interactions between filler particles and polymer matrix.

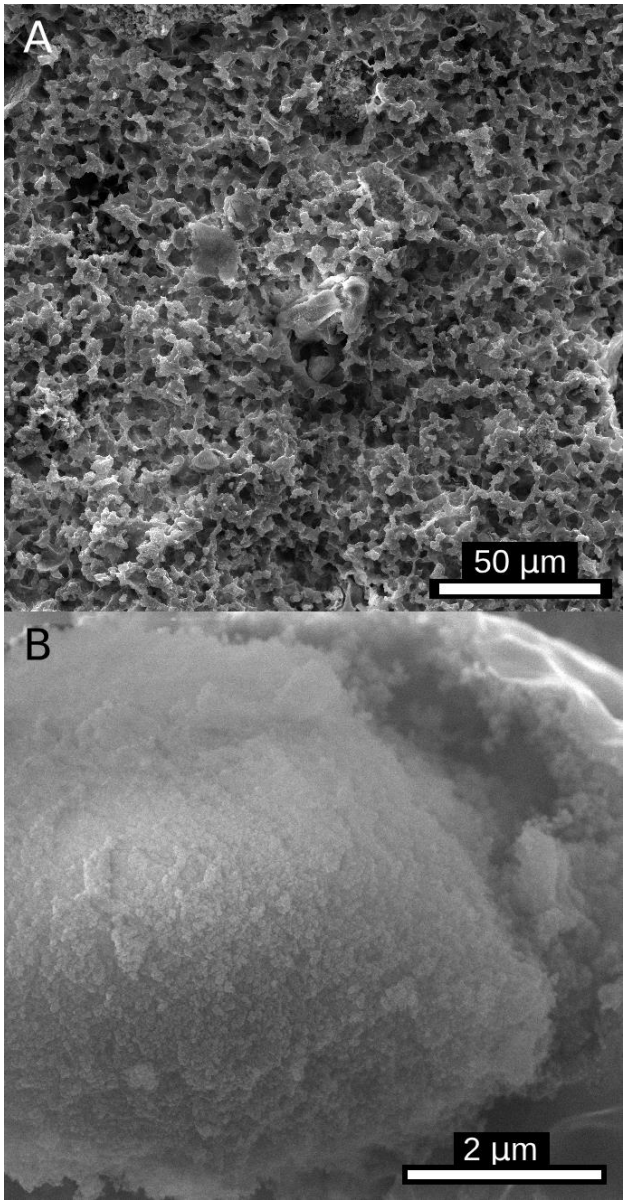

Fig. 4. SEM micrographs of lyophilized CH40 composite hydrogels after 28 days of in vitro bioactivity test. (A) 1000x magnification and (B) 30000x magnification.

IV. Conclusion

Composite hydrogels were synthesized by a simple method with high amount of filler particles incorporated. Swelling examinations gave an insight of composite structure, demonstrating higher degree of crosslinking of CH10 composites, which was ascribed to higher degree of mutual interactions between filler and matrix through chelating and hydrogen bonds. Changes in pH of SBF after immersion of composites showed higher ion exchange activity of CH40, indicating higher bioactivity, which was also confirmed by morphological investigations.

In general, this research gave us better understanding of how size and type of filler particles could influence the scaffold properties.

Sinthesis and Characterization of Hydroxyapatite and Fluorapatite Powders

Željko Radovanović, Abdulmoneim Mohamed Kazuz, Predrag Vulić, Lidija Radovanović, Đorđe Veljović, Rada Petrović, Đorđe Janaćković

Abstract— **The biomaterial powders of hydroxyapatite (HAp) and fluorapatite (FAp) were synthesized by a hydrothermal method. Powders were analyzed by energy-dispersive X-ray spectroscopy (EDS), field emission scanning electron microscopy (FESEM), and X-ray powder diffraction analysis (XRPD). EDS analysis shows the presence of non-stoichiometries FAp and HAp with molar ratio CA/P < 1.67. FESEM analysis of both powders indicates the presence of agglomerates of micrometric dimensions, while primary nanoparticles are rod-like. The Rietveld refinement of XRPD data showed that the single phase powders of FAp and HAp were synthesized. The results showed that obtained nanomaterials can be potentially applied in dentistry.**

Index Terms—**Biomaterial; Hydroxyapatite; Fluoroapatite; Nanoparticles; Rietveld refinement.**

I. Introduction

A new trend in the treatment of teeth is the application of material that would fill the cavity after removal of damaged dental tissue and also remineralize the surrounding tissue. The appropriate material could be a hydroxyapatite (HAp) as well as fluorapatite (FAp). Synthetic HAp, $Ca_5(PO_4)_3(OH)$, is similar to the inorganic part of bones and the dentine of teeth. It is biocompatible, bioactive, nontoxic, and osteoconductive [1, 2]. Replacement of the OH^- groups in HAp with F^- gives FAp, an implant material with better hardness, greater stability, less solubility and better antimicrobial effect than HAp [1].

Taheri *et al.* [3] synthesized the FAp by hydrothermal method at different pH values and temperatures. They found that the pH value of hydrothermal solution is more significant factor than temperature in terms of shape and dimension of the synthesized FAp. Ge *et al*. [4] obtained FAp after heat treatment at 600 °C in a water vapor environment for 3 h started from the as-deposited amorphous fluoridated calcium phosphate. They revealed that FAp had significantly better antibacterial activity than HAp. Stanić *et al.* [5] synthesized FAp powders by neutralization method. They found that the antimicrobial activity of the samples increases with the increase of concentration of $F^-$and decrease of pH value of saline solution. Zhao *et al*. [6] have shown that by the solution combustion method is possible to obtain single phase FAp and HAp starting from inexpensive raw materials and applying relatively simple preparation process and low-cost experimental installation.

The aim of this study was to synthesize the pure nanosized powders of FAp and HAp and investigate the properties of these materials. For this purpose, modified hydrothermal synthesis was applied.

II. Materials and Method

FAp and HAp powders were synthesized by a previously described modified hydrothermal method [7–10]. Pure HAp was synthesized from stoichiometric quantities of the chemicals: $NaH_2PO_4 \cdot 2H_2O$ (VWR Prolabo, 99.8%), NH_4OH (Zorka Pharma, p. a.) and $Ca(NO_3)_2 \cdot 2H_2O$ (Roth, ≥ 98%). In the synthesis of FAp, beside aforementioned chemicals, NaF (Riedel de Haen, 99%), were also used. Synthesis was performed with a constant molar ratio Ca/P = 1.67. After dissolution of the chemicals in 2 L of distilled water, the dish with the solution was inserted into an autoclave, previously filled with the 1.5 L of distilled water. The solution was heated at 160 °C for 3 h. After slow cooling, the obtained suspension was filtered, and the residue was washed with distilled water and dried at 105 °C for 4 h.

Energy-dispersive X-ray spectroscopy (EDS) of the powders was performed on a Jeol JSM 5800 SEM with a SiLi X-Ray detector (Oxford Link Isis series 300, UK).

The morphologies of the powders were observed by Tescan Mira 3 XMU field emission scanning electron microscopy (FESEM). Before analysis, the powders were coated with Au using a Polaron SC502 sputter coater. The particle size distribution was determined and presented using Mira software and Microsoft Excel programme, respectively.

The X-ray powder diffraction (XRPD) measurements were performed on a Rigaku SmartLab diffractometer using Cu *Kα* radiation, at 40 KV and 30 MA, in Bragg–Brentano geometry.

Diffraction data were collected in the range $5° < 2\theta < 120°$ (scan speed: 1° min^{-1}, step width: 0.01° 2θ) at room temperature.

III. Main Results

The atomic % of O, Ca, P and F were determined from the results of EDS analysis (Table I). This analysis shows the presence of non-stoichiometric HAp and FAp with molar ratio Ca/P < 1.67, which means that in both cases Ca-deficient apatite is synthesized.

TABLE I
EDS results for FAp and HAp powders.

Atomic %	Powder	
	HAp	**FAp**
O	72.71±0.23	66.16±1.06
F	–	5.00±0.58
P	11.53±0.05	11.58±0.27
Ca	15.75±0.20	17.26±0.69
Ca/P	1.37	1.49

The FESEM micrographs of the hydrothermally obtained HAp and FAp powders are shown in Fig. 1. Both powders consist of rod-like nanosized particles with average particle size of 87±17 nm for HAp and 87±20 nm for FAp. Also, the particle size distribution (Fig. 2.) are very similar and more than 60 % of particles are in the range of 70–90 nm for both powders. The particles form the agglomerates of micrometric dimensions. In the case of HAp, the agglomeration is more pronounced.

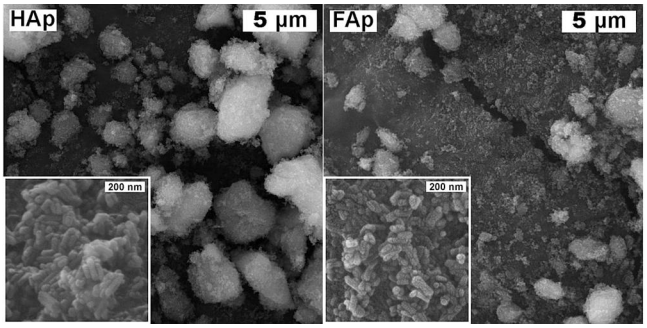

Fig. 1. FESEM micrographs of the HAp and FAp powders.

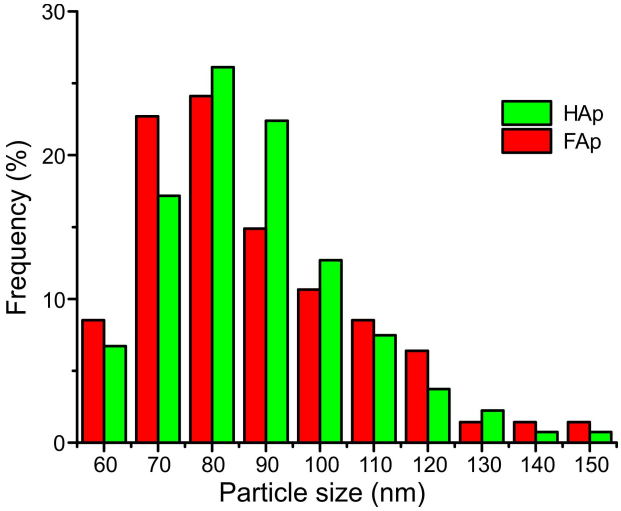

Fig. 2. Particle size distribution of the HAp and FAp powders.

TABLE II
Crystallographic and Rietveld refinement parameters of HAp and FAp.

Phase	**HAp**	**FAp**
Crystal system	hexagonal	hexagonal
Space group	$P6_3/c$	$P6_3/c$
a [Å]	9.4205(1)	9.3760(1)
c [Å]	6.88151(9)	6.88276(9)
V [Å^3]	528.9(1)	524.0(1)
Crystallite size [Å]	346(1) [–0.356, 0.935, 0]	330(1) [0.356, –0.935, 0]
Crystallite size [Å]	346(1) [0.935, 0.356, 0]	330(1) [0.935, –0.356, 0]
Crystallite size [Å]	886(9) [0, 0, 1]	983(1) [0, 0, 1]
Strain [%]	0.096(2)	0.105(1)
R_{wp} [%]	4.87	4.92
R_p [%]	3.76	3.82
R_e [%]	3.92	3.92
χ^2	1.5414	1.5744
S	1.2451	1.2548
Maximum shift/e.s.d.	0.081	0.022

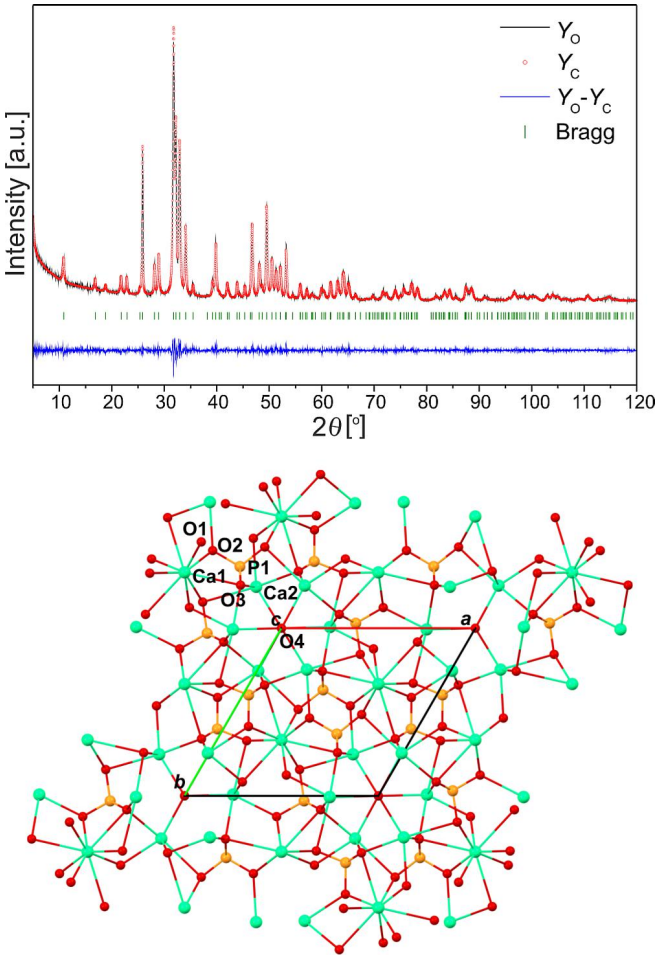

Fig. 3. Rietveld refinement (up) and crystal packing diagram in *ab* plane (down) of HAp.

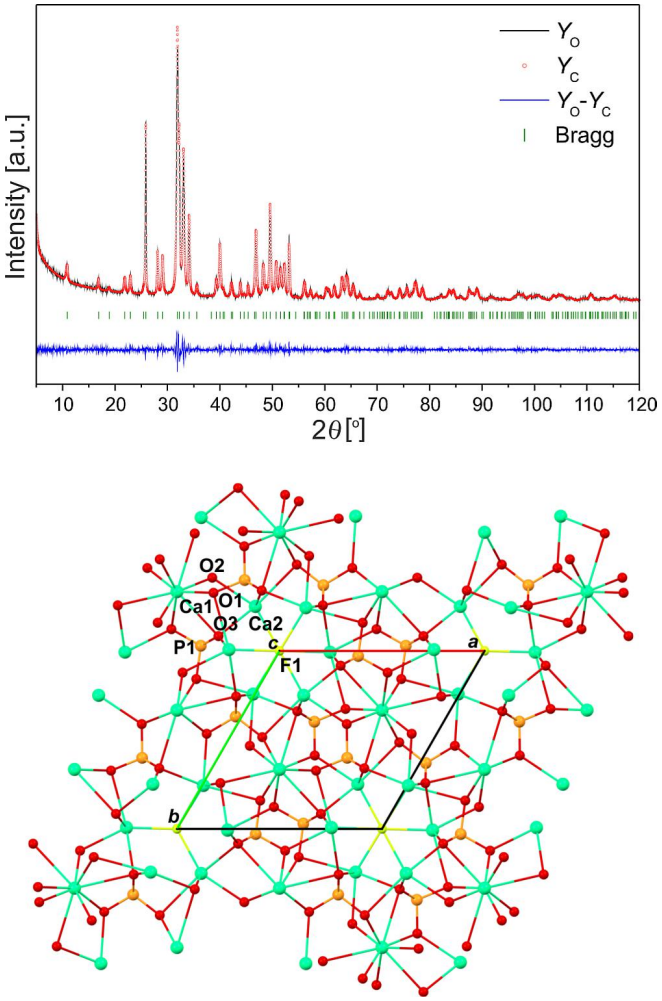

Fig. 4. Rietveld refinement (up) and crystal packing diagram in *ab* plane (down) of FAp.

XRPD patterns of HAp and FAp (Figs. 3 and 4, respectively) are very similar, but the peaks in the XRPD pattern of FAp are mildly shifting to higher values of 2θ angles indicating that unit cell of FAp is smaller.

The structures of HAP and FAp are presented in Figs. 3 and 4, respectively. The both structures crystallize in the hexagonal space group $P6_3/c$, with two formula units $Ca_5(PO_4)_3OH$ per unit cell, for HAp and with two formula units $Ca_5(PO_4)_3F$ for FAp. The lattice parameters for both structures are presented in Table II, from which it can be seen that unit cell of FAp is slightly smaller because of the substitution of OH^- group with F atom. Also, the crystallites of HAp and FAp are more elongated along the *c* axis (Table II) which is in accordance with rod–like morphology of particles observed by FESEM.

Rietveld refinement showed that there is no deficiency of Ca atoms in the structures of HAp and FAp, so the ratio Ca/P < 1.67 obtained by EDS analysis can be attributed to the errors of this method.

TABLE III
SELECTED BOND LENGTHS (Å)FOR HAP AND FAP

HAp	FAp
Ca1–O1 2.401	Ca1–O1 2.392
Ca1–O2 2.452	Ca1–O2 2.449
Ca1–O3 2.836	Ca1–O3 2.820
Ca2–O1 2.703	Ca2–O1 2.689
Ca2–O2 2.365	Ca2–O2 2.367
Ca2–O3 2.329	Ca2–O3 2.338
Ca2–**O4** 2.396	Ca2–**F1** 2.312
P1–O2 1.536	P1–O1 1.537
P1–O1 1.535	P1–O2 1.542
P1–O3 1.537	P1–O3 1.542

The selected bond lengths for HAp and FAp are listed in Table III. The Ca2–F1 bond length in FAp is shorter than Ca2–O4 (O4 is from the OH^- group) bond length in HAp, which can possibly be the reason for smaller unit cell of FAp.

IV. CONCLUSION

The pure, rod-like nanoparticles of HAp and FAp, suitable for application in teeth treatment, have been prepared by simple hydrothermal synthesis. Due to the presence of very small particles, using these materials in filling the tooth's canal is more preferable in comparison with similar materials but with microsized particles .

The future investigations will be oriented towards the synthesis of nanosized Ca-deficient HAp and FAp powders that could be doped further with different metal ions (Mg^{2+}, Si^{4+}, Na^{+}, Cu^{2+}, etc.). Also, the composite materials will be prepared by mixing of the appropriate ratio of HAp and FAp and their potential use as dental material will be examined.

The fabrication of dental insert based on magnesium doped hydroxyapatite and its shear bond strength with Maxcem dental cement

Tamara Matić, Maja Ležaja Zebić, Vesna Miletić, Sanja Jevtić, Rada Petrović, Djordje Janaćković, Djordje Veljović

***Abstract*—The polymerization shrinkage (PS) presents the cause of the secondary caries, one of the most common reasons for high failure rate of dental restorations. In order to lower PS and improve the lifespan of dental restorations, inorganic dental inserts based on hydroxyapatite (HAP) have been proposed. The aim of this study was to fabricate dental inserts based on hydroxyapatite doped with 5 mol. % of magnesium ions (Mg-HAP) and investigate its bonding ability with commercially available dental cement for possible application in restorative dentistry. The Mg-HAP inserts were characterized using X-ray diffraction (XRD) analysis, energy dispersive X-ray (EDX) analysis and scanning electron microscopy (FE-SEM). Bonding ability of the untreated inserts with Maxcem cement was measured by shear bond strength (SBS) test, and the type of fracture was analysed. The obtained average SBS value of the untreated Mg-HAP inserts with Maxcem cement was 3.1 MPa, with "adhesive" fracture type.**

***Index Terms*— hydroxyapatite; magnesium; shear bond strength; dental insert**

I. Introduction

DENTAL resin-based composites (RBCs) have been widely used in restorative dentistry for repairing decayed or damaged tooth structure [1]. They have gained popularity owing to their extraordinary aesthetic appearance, especially their ability to vary restorations nuance in accordance with patients natural teeth colour. On the other hand, majority of performed restorations are in fact replacements of the failed restorations, due to high failure rate of the RBCs (up to 15 %) [2], and their relatively short lifespan (around 6 years) [3]. The most common reason for restoration failure is connected to the formation of secondary caries at the tooth-restoration margins [4-6].

During the curing of the RBCs, the distance between monomers decreases, which manifests as contraction of the polymer, known as a polymerization shrinkage (PS). The PS causes a micro-gap formation at the tooth-restoration margins which enables penetration of oral fluids and microorganisms toward the dental pulp. Bacteria (e.g. *Streptococcus mutans*) metabolize sugars to lactic acid and lowers pH, which demineralizes hydroxyapatite in the tooth structure and causes the caries formation. Moreover, large restorations in the posterior region have high failure rate due to RBCs inability to bear a high cyclic occlusal loading during mastication [7]. In addition, polymerization shrinkage imposes stresses on the tooth-restoration interface, which increases the chance of an interfacial failure of the restoration.

In order to lower the polymerization shrinkage of RBCs, inorganic dental inserts based on hydroxyapatite (HAP) were introduced [8,9]. Application of HAP based inserts, not only may improve biological response to the foreign material in the body, owing to HAPs bioactivity, biocompatibility and structural similarity to the inorganic part of the natural human bones and teeth, but also could improve restoration lifespan by decreasing the polymerization shrinkage. It was previously reported that utilization of HAP inserts has lowered the polymerization shrinkage by nearly three times [8]. In addition, HAP has intrinsic radio-opaque property and similar hardness to the natural tooth [10].

Magnesium ions were reported to stabilize β– tricalcium phosphate (β–TCP) phase during sintering process of HAP, by increasing its transition temperature into α–polymorph [11,12], which is undesirable phase, as it lowers the mechanical properties of the end product. Moreover, doping HAP with magnesium ions leads to a higher cell proliferation as well as to increased bioactivity, biocompatibility and improved mechanical properties [13-15].

The aim of this study was to fabricate dental inserts based on hydroxyapatite doped with 5 mol. % of magnesium ions and test the shear bond strength with commercially available dental cement for possible application in restorative dentistry.

II. Materials and Methods

Nanosized calcium-hydroxyapatite powder doped with 5 mol. % magnesium (Mg-HAP) was synthesized by a previously described modified hydrothermal method [16-18], starting from a solution of $Ca(NO_3)_2 \cdot 4H_2O$ (11.80 g), $Na_2H_2EDTA \cdot 2H_2O$ (11.18 g), $NaH_2PO_4 \cdot 2H_2O$ (4.68 g), urea (12.00 g) and $Mg(NO_3)_2 \cdot 6H_2O$ (0.641 g). The precursor solution was thermally treated in an autoclave at 160 °C for 3 hours, under pressure of 8 bar. The obtained precipitates were collected by vacuum filtration, flushed with deionized water and dried at 105 °C.

Synthesized Mg-HAP powder was pressed into cylindrical green compacts (d = 6 mm, h = 1.6 mm) by two-step pressing process using a high-quality cylindrical steel mould. The powder was firstly uniaxially pressed at 100 MPa and then isostatically pressed at 400 MPa (CIP-15, MTI Corporation, Richmond, USA), in duration of 1 min per step. Green compacts were then sintered at 1200 °C in high-temperature furnace (Elektron, Banja Koviljaca, Serbia) for 2 h at the heating rate of 20 °C/min. After sintering, the Mg-HAP inserts were naturally cooled down to the room temperature.

In order to determine elemental composition of the Mg-HAP powder, an energy dispersive X-ray (EDX) analysis was performed on Oxford Inca 3.2 coupled with the SEM Jeol JSM 5800, operated at 20 keV. The results of EDX analysis were presented as average arithmetical values of three measurements taken at different areas of the sample, at the 1000 times magnification.

Phase composition of Mg-HAP powder and sintered insert was determined by X-ray diffraction analysis (XRD) conducted on Ital Structure APD 2000 X-ray diffractometer with CuKα radiation (1.54 Å) in the 2θ angle ranging from 20° to 60° with a scan step 0.02° s^{-1}. Identification of the phases was accomplished by comparing the experimental XRD patterns with standards cards: JCPDS 09-0169 and JCPDS 09-0432 for β–TCP and HAP respectively.

A scanning electron microscope (Tescan FE-SEM Mira 3 XMU, Tescan a.s., Brno, Czech Republic) operated at 20 keV was used to characterize the surface microstructure and cross section of the Mg-HAP inserts. The samples were coated with gold using a sputter coater (Polaron SC503, Fisons Instruments, Ipswich, UK).

Shear bond strength between Mg-HAP inserts commercially available restorative material – Maxcem cement (Maxcem Elite, Kerr, Italy) was measured by SBS test. As Maxcem cement belongs to group of "self-etch" and "self-adhesive" restorative materials, it was applied on untreated inserts surface, solely copiously rinsed with water and mildly air-dried. A custom-made mould used in this study was of the following dimensions: 6 mm in lower diameter and 2 mm high for the insert placement; 3 mm in upper diameter and 2 mm high for application of the restorative material. Each sample was prepared by placing an insert into the mould and applying Maxcem cement on the inserts top surface. In order to initiate polymerization LED light-curing unit (LEDition, Ivoclar Vivadent, Schaan, Liechtenstein) was used during 10 s at an intensity of 800 mW/cm2.

SBS test was performed on universal testing machine (Force Gauge PCE-FM200, Southampton, United Kingdom), using a knife-edge shearing blade. Force was applied at 1 mm distance of the restorative material-insert interface at 1 mm/min speed, until fracture. SBS (τ) was calculated using the maximum force reached (*F* [N]) and the bonded surface area (*A* [mm^2]) following the equation:

$$\tau = F/A \text{ [MPa]} \quad (1)$$

The type of fracture was analysed and classified as: "adhesive" (fracture at the material-insert interface), "cohesive" (fracture in the insert or material) or "mixed".

III. Results

The results of EDX analysis of the Mg-HAP powder is shown in the Table I. The presence of magnesium as dopant in Mg-HAP insert was confirmed. The Ca/P ratio was less than stoichiometric (1.67), implying that obtained hydroxyapatite was deficient in calcium and expected to undergo HAP-β–TCP phase transition during sintering. Illustration must be inserted in the text.

TABLE I
THE COMPOSITION OF THE MG-HAP POWDER

Ca [at.%]	P [at.%]	Mg [at.%]	Ca/P ratio
11.59	8.00	0.27	1.45

The XRD pattern of the as-synthesized Mg-HAP powder sample show characteristic peaks for calcium-hydroxyapatite, suggesting that monophasic powder was obtained (Fig. 1.a). The XRD pattern of the Mg-HAP sample upon sintering at 1200 °C is shown in Fig. 1.b. It is well documented that calcium-hydroxyapatite undergoes phase transition into β–TCP at 800 °C, and further transforms into α–TCP at 1125 °C [11,19]. The β–α phase transition is non desirable as it lowers mechanical properties of the end product [12]. According to the XRD pattern of the Mg-HAP sintered insert it may be concluded that β–α phase transition did not take place. Magnesium is reported to be able to stabilize β–TCP structure by postponing the β–α transition to the higher temperatures [11,13,15], which explains the absence of the α–TCP phase upon sintering at 1200 °C. The phase composition of the Mg-HAP inserts indicated that biphasic structure with equally dominant HAP and β–TCP phases was obtained.

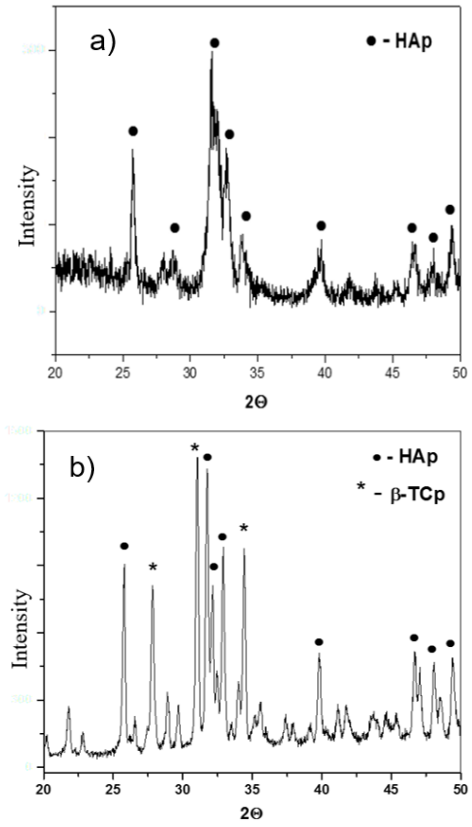

Fig. 1. XRD patterns of: a) Mg-HAP powder b) Mg-HAP insert sintered at 1200 °C

The results of the SEM analysis of the surface microstructure and cross section of the Mg-HAP inserts are shown in Fig. 2. As seen in the micrograph of the insert cross section (Fig. 2.a), the remained porosity upon sintering was relatively low, with spherical pores around 500 nm in size. In Fig. 2.b it is noticeable that the Mg-HAP inserts consisted of polyhedral grains varying in size from few hundred nanometres to about 1.5 micrometres.

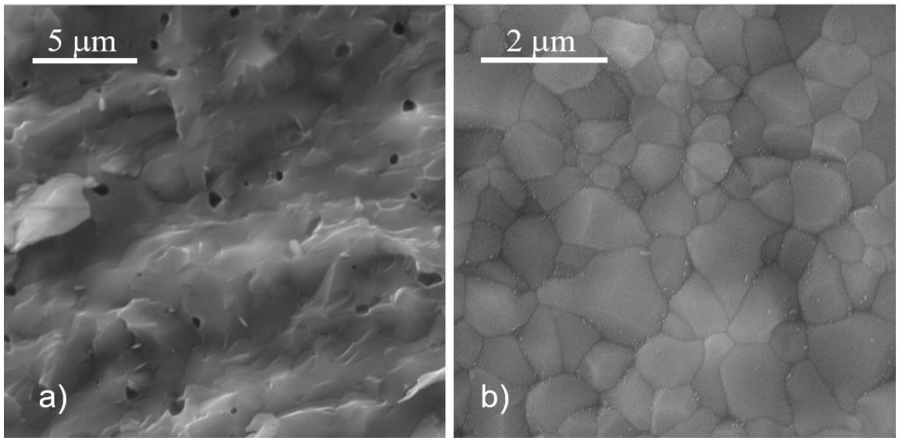

Fig. 2. SEM micrographs of the Mg-HAP inserts sintered at 1200 °C: a) cross section; b) surface microstructure

The results of shear bond strength (SBS) test shown in Table II indicate a relatively low bonding ability of the Maxcem cement and the untreated Mg-HAP inserts, with an average SBS value of 3.1 MPa. Although Maxcem cement is a "self-etch" and "self-adhesive" cement, when applied to the untreated surface of the Mg-HAP inserts, the bonding ability was relatively poor. This is further confirmed with the type of fracture being mostly "adhesive". The obtained results are in good agreement with previously reported study [8] where different restorative materials have manifested low bonding ability (avg. SBS values ranging from 0.7-2.2 MPa) with the HAP inserts and "adhesive" fracture type, when applied without an adhesive pre-treatment of the inserts surface. Possible improvement of the SBS should involve pre-treatment of the inserts surface, which will be an object of the future studies.

TABLE II
THE RESULTS OF THE SBS TEST

Sample	SBS [MPa]	Fracture type
1	4.36	adhesive
2	4.25	adhesive
3	2.47	mixed
4	1.96	adhesive
5	2.29	adhesive

IV. CONCLUSION

Dental inserts based on hydroxyapatite doped with 5 mol. % of magnesium ions were successfully fabricated. EDX analysis confirmed presence of magnesium ions as dopant species. The results of XRD analysis of the Mg-HAP inserts sintered at 1200 °C indicated that biphasic HAP-β–TCP structure was obtained. According to SEM analysis, the obtained inserts consisted of polyhedral grains varying in size from few hundred nanometres to about 1.5 micrometres. The remained porosity was relatively low, with spherical pores around 500 nm in size. Shear bond strength (SBS) value of the untreated Mg-HAP inserts with Maxcem cement was 3.1 MPa, with "adhesive" type of the fracture. Although Maxcem cement is a "self-etch" and "self-adhesive" cement, the obtained results indicate that there was low adhesion of the cement with untreated surface of the insert. Possible improvement of the SBS should involve pre-treatment of the inserts surface, which will be an object of the future studies.

Nova metoda za odgrevanje uzoraka amorfnih legura povorkom pravouganih strujnih impulsa modulisanog trajanja

Jelena Orelj, Nebojša Mitrović

Apstrakt— Nalaženje optimalnih svojstava magnetno mekih amorfnih/nanokristalnih legura je neophodno radi dostizanja najboljih funkcionalnih karakteristika savremenih električnih naprava u kojima se one koriste. Za postizanje ovog cilja neophodna je optimizacija termičkih tretmana koje je potrebno prilagoditi primenama ispitivanih legura. Magnetni senzori na bazi magnetoimpedansnog MI-efekta načinjeni od amorfnih / nanokristalnih žica - mikrožica zahtevaju potpuno specifične termičke tretmane, najvećim delom zasnovane na odgrevanju strujnim impulsima. U tu svrhu je razvijena nova metoda odgrevanja pomoću povorke pravougaonih strujnih impulsa modulisanog trajanja.

Ključne reči— Amorfne legure, nanokristalne legure, odgrevanje, povorka strujnih impulsa, modulisano trajanje

I. UVOD

OPTIMIZACIJA parametara termičkih tretmana sa stanovišta postizanja najboljih funkcionalnih svojstava (magnetnih i mehaničkih karakteristika) amorfnih i nanokristalnih legura se može izvoditi ili klasičnom metodom (odgrevanje u peći [1-3]) ili brojnim alternativnim metodama (odgrevanje strujnim impulsima [3-10], laserom [11]), mikrotalasnim zračenjem [12]). Sve navedene metode imaju razne varijante kod kojih se varira: prisustvo spoljašnjeg magnetnog polja [13]/mehaničkog naprezanja [14], maksimalno dostignuta temperatura odgrevanja, brzina grejanja, dužina tretmana, itd.

Cilj termičkih tretmana je ili dostizanje optimalno relaksirane mikrostrukture (klasične legure na bazi gvoždja Fe i kobalta Co) ili formiranje nanostrukture (sistemi nanokristalnih legura na bazi gvoždja Fe). Amorfne legure na bazi kobalta poseduju najbolja magnetna svojstva u stanju optimalno relaksirane amorfne strukture gde su otklonjene slobodne zapremine i zaostala naprezanja nastala tokom procesa brzog hladjenja prilikom dobijanja samih žica. Prilikom ispitivanja optimalnih svojstava nanokristalnih legura na bazi gvoždja evidentirano je očuvanje dobrih mehaničkih svojstava pri odgrevanju jednosmernim strujnim impulsima [5-7] nasuprot uzoraka odgrevanih u peći na temperaturama nešto nižim od temperature kristalizacije.

Magnetni senzori na bazi magnetoimpedansnog efekta kod amorfnih/nanokristalnih legura (u obliku traka ili žica) su posebno interesantni za ispitivanje optimizacije njihovih svojstava primenom metoda odgrevanja strujnim impulsima [15-17].

Jelena Orelj – Univerzitet u Kragujevcu, Fakultet tehničkih nauka Čačak, Svetog Save 65, Srbija (e-mail: jelena.orelj@ ftn.kg.ac.rs.)

Nebojša Mitrović – Univerzitet u Kragujevcu, Fakultet tehničkih nauka Čačak, Svetog Save 65, Srbija (e-mail: nebojsa.mitrovic@ ftn.kg.ac.rs).

Metode odgrevanja na osnovu Džulovog efekta baziraju se na korišćenju ili jednosmerne (DC) ili naizmenične (AC) struje.

II. EKSPERIMENTALNI DEO

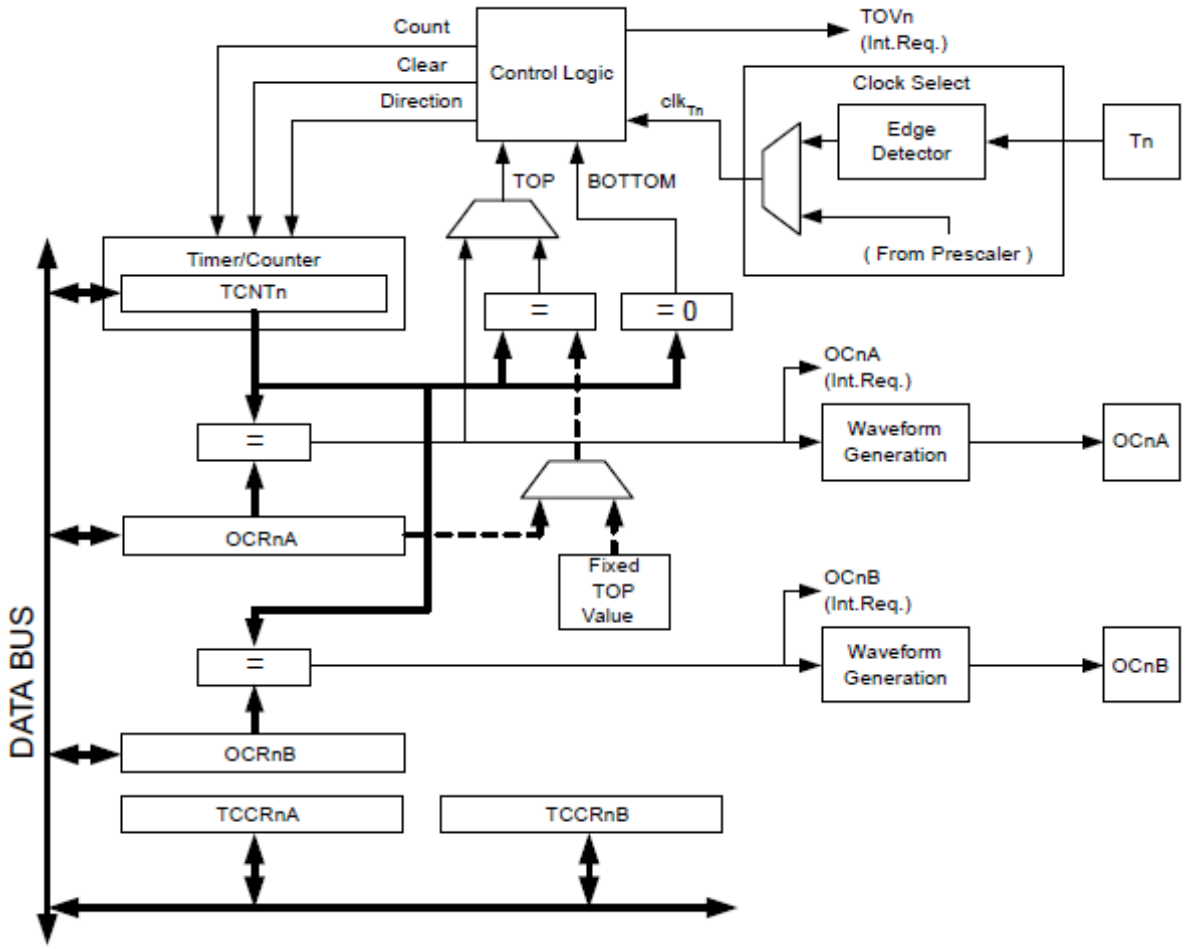
Pripremljena je potpuno nova aparatura za odgrevanje uzoraka amorfnih legura (mikrožica ili traka) tzv. metodom odgrevanja sa povorkom pravouganih strujnih impulsa modulisanog trajanja, odnosno modulisanog faktora popune. Radi se o cikličnom odgrevanju uzoraka širinski modulisanim strujnim impulsima, pri čemu je modulacija trajanja impulsa izvršena po kosinusnom zakonu trajanja četvrtine peroioda. Dakle, kroz uzorak se u ciklusima propušta PWM (eng. Pulse Width Modulation) strujni signal određenog trajanja, koje se utvrđuje na osnovu kritične vrednosti temperature do koje sme da se odgreva uzorak, te se na taj način vrši jednostavno, efikasno i kontrolisano odgrevanje uzorka. S obzirom na opisani postupak, metoda je nazvana Cyclic Current Annealing by Square Pulse Width Modulation – CCASPWM.

Suština algoritma za odgrevanje datog uzorka strujnim PWM signalom se sastoji u tome da se na osnovu odredjene temperature kristalizacije T_x (npr. korišćenjem DSC/DTA analize), odredi broj impulsa različitog faktora ispune (eng. *Duty Cycle*) i to od najšireg do najužeg impulsa, kojima će se uzorku predati odredjena količina toplote, odnosno povećati temperatura približno do temperature T_x. Pri tome treba voditi računa da se omogući postepeno približavanje temperaturi kristalizacije T_x, kako ne bi došlo do kristalizacije uzorka, koja je nepovoljan efekat za magnetna svojstva amorfnih žica na bazi kobalta Co. Dakle, u ovom slučaju cilj metode odgrevanja je dostizanje optimalno relaksirane amorfne mikrostrukture.

Uspešnost ove metode će se ogledati upravo u što boljoj kontroli procesa odgrevanja i efikasnom dobijanju optimalnih magnetnih svojstava u odnosu na do sada korišćene metode strujnog odgrevanja. Promenljivošću faktora ispune povorke impulsa upravo se obezbeđuje efikasna kontrola nad procesom odgrevanja.

S obzirom da realizacija PWM signalnog generatora u diskretnoj analognoj tehnici može da da loše i nepouzdane rezultate usled promena parametara ovih kola, generisanje PWM strujnog signala, mnogo preciznije i otpornije na smetnje, postignuto je u digitalnoj tehnici.

U tu svrhu korišćen je 8-bitni AVR ATmega328p mikrokontroler, koji kao i mnogi drugi mikrokontroleri ima već implementiran generator PWM signala u vidu tajmera/brojača i odgovarajućih upravljačkih registara, što je prikazano na Sl. 1.



Sl. 1. Pojednostavljena blok šema PWM modula unutar ATmega328p mikrokontrolera [18]

Na ovaj način su izbegnuti svi nedostaci analognih PWM generatora, kao što je nedefinisano stanje signala – glich, šumovi i slično. ATmega328p mikrokontroler ima tri 8 – bitna tajmera/brojača (Timer 0, Timer 1, Timer 2), koji mogu da rade u četiri različita režima rada (Fast mode, Phase Correct mode, Phase and Frequency Correct mode i CTC mode). Pri tome generisani PWM signal može da ima promenljiv faktor ispune i/ili frekvenciju signala.

U konkretnom slučaju, a s obzirom na potrebe tehnike odgrevanja, iskorišćen je ***Phase Correct* (PC)** režim rada koji je realizovan na "nultom" tajmeru (**Timer 0**). Metoda odgrevanja je realizovana sa konstantnom frekvencijom i promenljivim faktorom ispune. Primenjeni režim rada obezbedjuje tačno definisanje trenutaka pojavljivanja i trajanje impulsa kojima se odgreva uzorak, a s obzirom da je zahtevana tačnost reda ms, ovaj režim rada se pokazuje kao odgovarajući izbor.

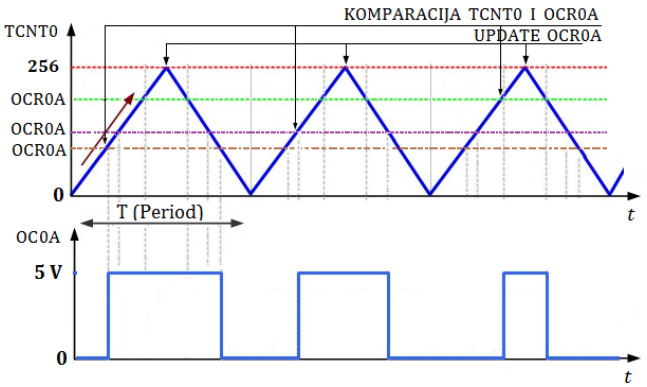
Korišćenjem brojača sa visokom rezolucijom, odnos impuls/pauza se moduliše da odgovara specificiranom nivou analognog signala, pa za dati programski kôd kojim se menja stanje odgovarajućih registara (OCRnA/OCRnB) sa Sl. 1. dobija se željeni PWM signal, Sl. 2 (OCnA/OCnB).

Kako je prilikom odgrevanja uzoraka korišćen niz impulsa PWM signala od najšireg do najužeg impulsa, signal je generisan na OCnA, odnosno na OC0A izlazu (OCnB predstavlja invertovan OCnA).

Frekvencija (a samim tim i perioda) željenog PWM signala za *PC* režim rada može se izračunati na osnovu sledećeg obrasca:

$$f_{OCnxPCPWM} = \frac{f_{clk}}{N \times 510}, \qquad (1)$$

gde je N faktor skaliranja: 1, 8, 64, 256 ili 1024.



Sl. 2. Vremenski dijagram PWM signala za Phase Correct režim rada na OC0A *izlazu [18]*

Generisanom PWM signalu se pristupa preko digitalnih pinova 5 (OC0B) i 6 (OC0A), mikrokontrolera ATMega328P (Sl. 5). To je zapravo izlaz "nultog" tajmera/brojača. U konkretnom slučaju signalu se pristupa sa pina 6. Menjanjem stanja u komparacionim registrima OCR0A i

OCR0B (koja se porede sa sadržajem tajmera/brojača TCNT0) dobija se odgovarajuća sekvenca impulsa različitog faktora popune. Programski kôd kojim je generisan željeni PWM strujni signal na pinu 6:

```
#include <avr/io.h>
#include <util/delay.h>

int main(void){

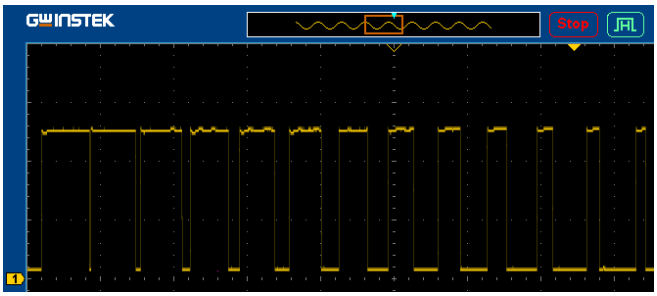
 // definisanje izlaza
  pinMode(5, OUTPUT);
  pinMode(6, OUTPUT);

  // inicijalizacija tajmera  TIMER0
  // fphase_correctPWM=16 MHz/(1024*510)=30.64 Hz
  //Period Tphase_correctPWM=32.64 ms

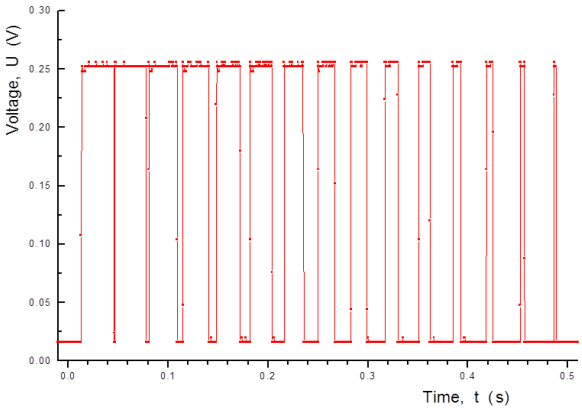
  TCCR0A = 0b10110001; //Phase Correct rezima rada
  TCCR0B = 0b0000101; //faktor skaliranja 1024
  TCNT0 = 0;    // Reset TCNT0 (Timer0/brojac)
  OCR0A = 0;    // Inicijalizacija registara A i B
  OCR0B = 0;

unsigned char duty_cyc_a, duty_cyc_b;
duty_cyc_a=255;      //Inicijalizacija registra OC0A      duty_cyc_b=0;
//Inicijalizacija registra OC0B
int n=16;
  for(int br_T=0;br_T<n;br_T++){
    if(duty_cyc_a>=0) {
      OCR0A=duty_cyc_a;
        duty_cyc_a-=n+1;
    }
 }
return 0;
}
```

Za potrebe strujnog odgrevanja amorfne žice generisan je PWM signal periode ~ 32 ms (faktor skaliranja N=1024), promenljivog faktora ispune u toku petnaest perioda (koliko traje jedna PWM sekvenca), kao što se može videti na ekranu digitalnog osciloskopa na Sl. 3. ili grafički na Sl. 4.



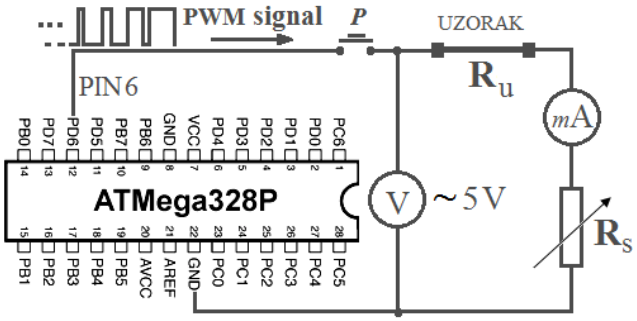
Sl. 3. Povorka pravouganih impulsa modulisanog trajanja na ekranu digitalnog osciloskopa.



Sl. 4. Grafički prikaz povorke pravouganih impulsa modulisanog trajanja.

Tu promenu je moguće kontrolisati po sinusnom ili nekom drugom zakonu, što ovoj metodi daje prednost u pogledu kontrole procesa odgrevanja uzorka.

Formirana povorka naponskih impulsa se dovodi na uzorak sa električnom otpornošću R_u (Sl 5.) i na taj način formira povorka strujnih impulsa na ispitivanom uzorku amorfne legure.



Sl. 5. Blok šema formiranja povorke pravouganih strujnih impulsa modulisanog trajanja na uzorku amorfne legure - električna otpornost R_u.

Za buduće zahtevnije, superiornije, pa i komplikovanije algoritme strujnog odgrevanja uzoraka amorfnih legura (žice), verovatno će biti interesantna preostala dva režima rada tajmera/brojača ili uopšte generisanje PWM signala sa promeljivom frekvencijom, tj. promenljivom periodom unutar PWM signala. Za sada su se autori odlučili da koriste što jednostavniju, a veoma preciznu tehniku.

III. Zaključak

Savremeni razvoj digitalne tehnike za generisanje PWM signala je omogućio značajno unapredjenje specifičnih termičkih tretmana amorfnih legura. U ovom radu je pokazano korišćenje 8-bitnog mikrokontrolera za razvoj nove metode odgrevanja pomoću povorke pravougaonih strujnih impulsa modulisanog trajanja. Za potrebe odgrevanja strujnim impulsima, amorfnih magnetno mekih žica koje će se koristiti za izradu magnetnog senzora na bazi magnetoimpedasnog efekta, uspešno je generisana povorka pravougaonih PWM signala periode ~ 32 ms.

Zahvalnica

ABSTRACT

In order to attain the best functional characteristics of electric devices made by amorphous or nanocrystalline soft magnetic alloys it is necessary to perform detailed research of their properties. Optimization of applied thermal treatments is the crucial task devoted to development magnetic sensors based on magnetoimpedance (MI) effect in amorphous or nanocrystalline wires-microwires. Different current annealing techniques with a lot of varieties were widely used. Therefore, the new method for cyclic current annealing of amorphous alloy samples by applying square pulse with modulation (CCASPWM) and 32 ms duration was developed.

New Method for Cyclic Current Annealing of Amorphous Alloys by Square Pulse Width Modulation CCASPWM

METHODS OF COSMIC MUON IMAGING

(INVITED PAPER)

Istvan Bikit, Department of Physics, Faculty of Sciences, University of Novi Sad, Serbia
Dusan Mrdja, Department of Physics, Faculty of Sciences, University of Novi Sad, Serbia
Kristina Bikit-Schroeder, Department of Physics, Faculty of Sciences, University of Novi Sad, Serbia

ABSTRACT

Cosmic-ray muons can be used for imaging of large structures, or high-density objects with high atomic number. The first task can be performed by measurement of muon absorption within very thick material layers, while the second approach is based on muon multiple scattering. However, the muon imaging of small structures with low atomic number and density was not yet solved appropriately. Our research group has demonstrated recently completely new imaging method by cosmic-ray muons, based on the detection of secondary particles produced by muons in object material (I. Bikit et al, Novel approach to imaging by cosmic-ray muons, EPL 113 (2016) 58001). Novel imaging technique by cosmic-ray muons is based on the detection of secondary produced particles generated within materials and objects by passage of cosmic-ray muons. This method opens up possibility to obtain 2D and 3D images of small objects made of materials with low atomic number. The advances of "conventional" muon imaging systems based on muon absorption and scattering and detection of incoming and scattered muons will be presented, and compared with the new imaging technique. The possible applications of the new imaging technique will be discussed.

Thoron ^{220}Rn Exhalation Rate Measurement: Dependence of the Grain Size

Dunja Antonijević, Luka Rubinjoni, Andrija Janković, Igor Čeliković, Aleksandar Kandić, Boris Lončar

***Abstract*— Radon, ^{222}Rn with its progeny is considered as the second cause of lung cancer after smoking. On the other hand, thoron ^{220}Rn was often neglected since its concentrations in the indoor environment were considered to be smaller compared to radon concentrations and due to its short lifetime compared to radon. Nevertheless, there are regions that have thoron concentrations higher or comparable to radon concentrations. In this contribution, measurements of thoron exhalation rate of different materials as a function of grain size is presented. Measurements were performed using RTM1688-2 of Sarad Company.**

***Index Terms*—Thoron; Exhalation rate measurements; building material; grain size.**

I. Introduction

Radon is a noble gas with all its isotopes being radioactive. It is colourless, tasteless and odourless and therefore not detectable by human senses. Radon itself is not hazardous for health since majority of inhaled radon is exhaled before decaying in lungs. The main health hazard are its progeny which tend to attach to aerosols and when inhaled they tend depose in the lungs and irradiate surrounding tissue as they decay.

In 1988, International Agency for Research on Cancer has identified radon as a human carcinogen [1]. Based on the more recent epidemiological studies performed in Europe, Asia and America, World Health Organisation (WHO) has identified radon as the second cause of lung cancer after smoking. Based on pooled studies, it is estimated that between 3 and 14% of all lung cancers are due to exposure to radon and its progeny [2].

Influence of ^{220}Rn (thoron) to population exposure has often been neglected. It is estimated that thoron and its progenies contribute only 10% of the population exposure to radon [3]. Firstly, thoron half-life ($T_{1/2}$ = 55.6 s) is significantly shorter than half-life of radon ($T_{1/2}$ = 3.82 days) having therefore substantially shorter diffusion length. While the main source of indoor radon is soil beneath dwelling and the second one is building material, the main source of thoron is building material. Soil can be significant source of thoron in dwellings that does not have foundation or it is poor condition. Furthermore, due to short diffusion length of thoron, its concentration rapidly decreases several centimeters from its source, i.e. building material while radon concentration in the room is considered to be uniform. In spite of the abovementioned, the regions with higher effective doses due to thoron compared to radon, could be found [4-7].

In the era of increasing of energy-efficiency of homes, in old houses, doors and windows are being replaced with the new ones that are more tight, while new buildings are being built with new materials with better thermal isolation. This leads to decrease of air exchange rate and consequently to increase of indoor radon concentration [8, 9].

Therefore, there is an interest to perform exhalation rate measurements of thoron from building materials. Some of the typical methods are based on the use of continuous active devices such as semiconductors [10], or passive ones based on solid state nuclear track detectors [11].

It is known that exhalation rate from material does not depend only on the concentration of its predecessor, (^{226}Ra in the case of radon and ^{224}Ra in the case of thoron), but on the material properties such as: porosity, particle size, moisture content etc.

In this paper we are presenting the results of the thoron exhalation rate as a function of the grain size of the selected material. Measurements were performed using active device RTM1688-2 of Sarad Company.

II. Material and method

Measurement of thoron exhalation rate was performed on three different materials: soil sample, natural stone and brick block. Each sample was prepared in the same way: mechanically crashed and then sorted using sieves with different sizes. Thus, several particle size has been obtained: less than 0.5 mm, from 0.5-0.7 mm, from 0.7 to 1.2 mm, from

1.2-1.6 mm and from 1.6-2.1 mm.

Thoron mass exhalation rate measurements has been performed using the close-chamber method [12, 13]. Measuring sample was put in the 1.5 dm^3 volume chamber, which is in the close loop, using tubes, connected with the active device. Consequently thoron concentration in the chamber was measured. In Fig. 1, schematic representation of the measuring system is shown.

Thoron measurements were performed using active RTM1688-2 device. Thoron concentration was determined from the detection of the alpha particle emitted by ^{216}Po. Since half-life of the ^{216}Po is of the order of 0.1 s, equilibrium between thoron and ^{216}Po is established immediately. Duration of measurement was 20 minutes with sampling time of 5 minutes.

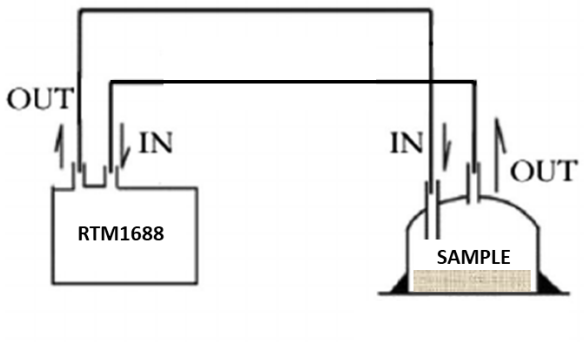

Fig. 1. Schematic representation of thoron exhalation rate measuring system.

Build-up of thoron in accumulation chamber can be expressed by following formula [11]:

$$C(t) = \frac{E_m m}{V\lambda}(1 - e^{-\lambda t}) + C_0 e^{-\lambda t} \quad (1)$$

Where $C(t)$ is the thoron concentration (Bq m^{-3}) in time t, E_m is the thoron mass exhalation rate (Bq kg^{-1} s^{-1}), m is the mass of the sample (kg), λ is the thoron decay constant, V (m^3) is the total volume of the measurement system including: volume of the chamber, active volume of the measuring device, tubes and C_0 is the initial thoron concentration (Bq m^{-3}) in the chamber.

Since measurement time is much longer than half-life of thoron, exponential term in equation (1) can be neglected and thoron concentration in the chamber can be expressed as:

$$C = \frac{E_m m}{V\lambda} \quad (2)$$

Showing that steady state thoron concentration in the chamber is achieved.

III. Main Results

Measurement of each sample lasted 20 minutes, with a sampling time of 5 minutes. Thoron concentration is therefore extracted from the dose received during 20 minutes measurement period. In Figure 2, one series of 4 thoron measurements for each sample type is presented.

Although, results within each thoron series agree within the uncertainty, there is large variation of measured thoron concentration, which leads to the large uncertainty of the deduced averaged thoron concentration.

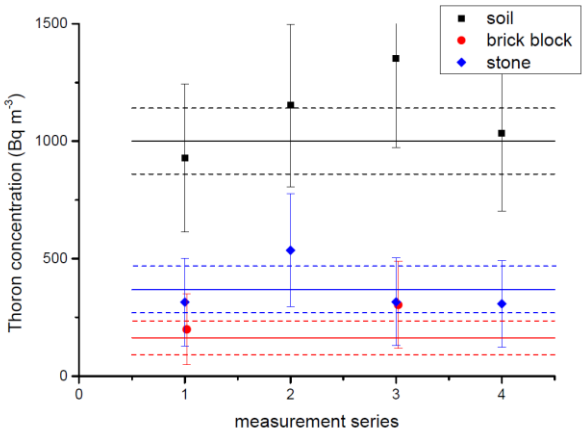

Fig. 2. Thoron measurement of each sample type. Deduced thoron concentration and its uncertainty are indicated with full and dashed lines, respectively.

In Table 1, an averaged thoron concentration for each sample type and particle size is presented together with the mass of each sample.

TABLE I
RESULTS OF MEASURED THORON CONCENTRATIONS FOR THREE DIFFERENT SAMPLES: SOIL, BRICK BLOCK AND NATURAL STONE AND FIVE DIFFERENT PARTICLE SIZES: EACH SAMPLE TYPE AND PARTICLE SIZES: 1) <0.5 MM, 2) 0.5-0.7 MM, 3) 0.7-1.2 MM, 4) 1.2-1.6 MM, AND 5) 1.6-2.1

Sample	Particle size [mm]	Mass [g]	Thoron concentration [Bq m^{-3}]
Soil	<0.7	244.77	1000±140
	0.7-1.2	198.86	990±170
	1.2-1.6	176.36	400±110
	1.6-2.1	154.02	500±120
Brick Block	<0.5	159.62	68±48
	0.5-0.7	157.05	93±55
	0.7-1.2	160.70	163±44
	1.2-1.6	151.09	39±38
	1.6-2.1	157.06	55±36
Natural Stone	<0.5	160.46	410±100
	0.5-0.7	163.72	370±100
	0.7-1.2	160.97	580±130
	1.2-1.6	162.26	770±150
	1.6-2.1	162.10	420±110

Thoron mass exhalation rate was estimated from the measured thoron concentration given in Table 1, using the

equation (1). Results are given in Figure 3, showing the dependence of mass exhalation rate as a function of particle size, for three different samples: soil, brick block and natural stone.

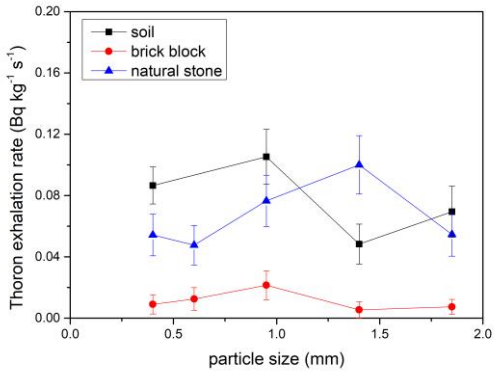

Fig. 3. Thoron mass exhalation rate measurements as a function of 5 different particle sizes: : 1) <0.5 mm, 2) 0.5 – 0.7 mm, 3) 0.7 – 1.2 mm, 4) 1.2-1.6 mm, and 5) 1.6-2.1 mm for three different samples: soil, brick block and natural stone.

Systematics of thoron exhalation rate as a function of particle size is given with a large measurement uncertainty, as shown in Figure 3. Although data indicate slight variation of thoron mass exhalation with particle size, these variation are within measurement uncertainty in the case of brick block and natural stone. Similar results were reported, elsewhere [14]. In the case of soil sample, there is statistical difference between exhalation rate of the first two samples and the last two samples. First two soil samples with the smaller particle diameter, has a higher exhalation rate, compared to the larger particles. This behaviour is envisaged, since for grains of smaller size there is higher probability that decay of ^{224}Ra will lead to thoron emanation from that grain.

.

IV. Conclusion

In this contribution, dependence of thoron mass exhalation rate on the grain size was investigated. For that purpose, close chamber method was used. Thoron concentration in the chamber was measured using active RTM1688-2 device. For two samples: brick block and natural stone it was not observed an increase of thoron exhalation rate with a decrease of grain/particle size as expected, possibly due to large measurement uncertainty and the size of particles. An increase of exhalation rate for two soil samples with the smallest grain size, compared to samples with larger grains was observed. Since all samples were measured at ambient humidity, some effect due to humidity could be observed. Therefore, it would be interesting to further investigate whether exhalation rate would be observed or more pronounced for smaller grain sizes and at different humidities at the same time.

Determination of Surface Contamination with Handheld Equipment

Marija M. Janković, Jelena D. Krneta Nikolić
Predrag M. Božović, Nataša B. Sarap, Milica M. Rajačić

***Abstract*—Surface contamination meters are used to detect the presence of radioactive substances on some surfaces. The level of contamination can be measured using portable handheld detectors. Factors that can affect the results are source to detector distance, source geometry. This paper presents the results of measuring alpha, beta and mixed alpha-beta surface contamination presented on printed spiked papers.**

***Index Terms*—surface contamination, alpha activity, beta activity, handheld equipment.**

I. Introduction

Radioactive surface contamination is unwanted radioactive material deposited in an uncontrolled manner in or on animate or inanimate objects so that their concentrations present either operational inconvenience or radiological hazard [1]. There are several ways in which radioactive contamination can be classified: (1) by the type of radiation emitted (alpha, beta and low energy beta emitters), (2) by the availability for or ease of transfer to other objects (fixed or loose), (3) or by the physical form of the contaminant.

Monitoring techniques for determination of surface contamination can be direct or indirect. Direct method implies direct measurement on the surface and indirect means using smears and measuring them on gamma spectrometric detector or gas proportional detector.

Due to the short range of alpha particles in air, direct monitoring of alpha activity presents several problems. To ensure the detection of alpha contamination by direct method, distance from surface to detector should be less than 5 mm [1]. The same situation is with low energy beta radiation. Beta particles have longer range in the air than alpha particles and the detection is easier, but the response on detector depends on the energy of beta radiation.

Indirect methods for analysis of surface contamination can be used when the geometry of the surface is not appropriate for the measurement on other types of spectrometers. For the contamination to be measured on the spectrometer, the radioactive material has to be removed from the surface using smears and monitored on a detector. This is not always possible or practical, especially if the measurement is made in the field. That is when using handheld measuring device is applied.

Handheld equipment has shield, which when closed prevents alpha and beta radiation from reaching the detector, enabling a gamma-only measurement to be made.

This paper presents the results of surface radioactivity contamination measurement done within the inter laboratory proficiency test under the Project RER/7/008 - Strengthening Capabilities for Radionuclide Measurement in the Environment and Enhancing Quality Assurance/Quality Control System for Environmental Monitoring.

II. The Method

Response of detectors on contamination depends on the type and energy of the radiation, the counting efficiency, the detection geometry, instrument electrical noise etc.

Handheld detector used for this investigation was Automess 6150AD-k (Fig.1) [2]. The probe 6150AD-k uses a sealed proportional counter which does not require refilling or flushing from external gas reservoirs [3]. It is sensitive to alpha, beta, and gamma radiation, however due to large sensitive area it makes surveying areas much easier. Additionally, it provides an electronic switch to the operating mode "alpha" where only alpha radiation is recognized and detected very sensitively because the background is much lower in this mode. A removable discriminator plate (1 mm thick stainless steel) allows distinguishing between beta and gamma radiation.

Adequate calibration of the field instruments is necessary for accurate measurements of total surface activity [4,5]. Alpha radiation emitters with energies similar to those expected of the contaminant in the field should be used as calibration sources. Sources used for calibration were ^{241}Am and ^{90}Sr (Table I).

Instruments have decay mode: alpha, beta and gamma. Detectors generally have efficiencies from 0 to 30 %.

TABLE I
AUTOMESS 6150 AD-K TEHCNICAL SPECIFICATIONS [P1]

Measuring instrument	6150AD-k surface contamination probe
Producer	Automess
Detector type	Proportional counter
Sensitive area of detector	17×10 = 170 cm^2
Calibration factor for Alpha ^{241}Am	0.074 (Bq/cm^2)/s^{-1}
Beta ^{90}Sr	0.011 (Bq/cm^2)/s^{-1}

Factor that may affect the detector efficiency is distance between source and detector because changes in the distance produce changes in the detector response especially for the alpha radiation. To minimize the effect of surface to detector distance it is recommended that the distance should be as small as possible. For alpha contamination it is recommended that the distance should not exceed 5 mm [1]

Source geometry can also affect the results. Calibration source should be similar to point source geometry. In our case printed sources have the same geometry as handheld detector.

Background count rate must be measured on the place where there is no potential high activity from local area (for example granite, or ceramic tiles…).

Surface activity can be calculated using the Equation (1) [6]:

$$A_s = \frac{N - N_0}{E_i E_s W} = \frac{N - N_0}{Es} \cdot C_s \qquad (1)$$

where:

As is surface activity in Bq cm^{-2}

N is count rate of the measurement in cps

N_0 is background count rate in cps

E_i is instrument efficiency in count per emission

E_s source efficiency in emission per Bq

W is the detector area in cm^2

C_S is the calibration factor equal to $1/E_iW$ [Bq cm^{-2}/s^{-1}]

In this measurement it is assumed that the source efficiency E_S is equal to 1.

Fig. 1. Handheld detector Automess 6150AD-k

III. THE RESULTS

Samples obtained by IAEA were spiked with ^{90}Sr (pure beta emitter) (sample 1), ^{244}Cm (almost pure alpha emitter) (sample 2) and mixture ^{90}Sr + ^{244}Cm (sample 3). Sample area for printed paper was 14 cm × 20 cm (Fig.2). Measurements were performed in the Radiation and Environmental Protection Department, Vinča Institute of Nuclear Sciences, within the Project: RER/7/008 - Strengthening Capabilities for Radionuclide Measurement in the Environment and Enhancing Quality Assurance/Quality Control System for Environmental Monitoring. On Figure 2 we can see the surface contamination samples delivered to the Laboratory. All samples were covered with plastic foil in order to prevent the damage or cross contamination of the samples during the transport. Also, samples were protected with foam frame that did not cover the spiked area, so the measurement could be conducted without removing it.

Fig. 2. Samples for determination of surface contamination

Firstly, for the sample 1 handheld detector was placed above the surface at 1 cm distance. Net count rate for sample was taken as average value of 10-15 measurements. For the sample 2 handheld detector was placed as close to the surface as possible without contact with surface. Net count rate for this sample was also taken as average value of 10-15 measurements. In case of sample 3, which contained mixture of alpha and beta emitters, firstly net count rate for alpha was measured without shield on detector in alpha mode and then for beta emitters measurement, the shield was placed back on the detectors, enabling us to measure in beta mode.

Background was measured 5 times in one point.

Since all the measurements were conducted in the same room, held on the room temperature of approximately 20°C and without changing the environmental parameters, the influence of the temperature on the measurement quality is minimized.

Positioning of the instrument above the sample could present a problem, so any potential support for the instrument should be utilized. Also, the distance for the measurement in alpha mode should be as small as possible without touching the surface itself in order to avoid the attenuation of the alpha particles in air. In this situation, that was accomplished by placing the detector on the protective frame of the sample, enabling us to achieve the distance of 1mm.

Since not all of the area of the sample was covered by the

surface of the instrument, the dimensions of the sample area that was covered by the detector had to be taken into account. This was achieved by multiplying the calibration factor with the ratio of the detector area and the area of the sample.

Measurement uncertainty was calculated as the combined measurement uncertainty with the coverage factor 1.

$$u(A) = \sqrt{u^2(N_0) + u^2(N) + u^2(C_s) + u^2(\mathrm{d})} \qquad (2)$$

where $u(N_0)$ is the relative uncertainty of the background count, $u(N)$ is the relative uncertainty of the measured sample count, $u(C_s)$ is the relative uncertainty of the calibration factor and $u(d)$ is the relative uncertainty of the detector-sample distance.

The relative uncertainty of the background count and measured sample count was determined as the standard deviation of the repeated measurements. For beta emission background, the standard deviation was around 5% and for the alpha emission it was around 2%. The relative uncertainty of the sample count ranged from 2.2% for alpha emission count in sample 2 to 7.9% for beta emission count in sample 3.

Since the calibration factor was obtained from the instrument manual, the uncertainty of this parameter was considered as negligible. The relative uncertainty of the detector-sample distance was estimated to be 1%.

The final results were obtained by taking the mean value of the repeated count measurements and applying the Equation (1).

Results with the appropriate measurement uncertainties are given in Table II.

TABLE II
RESULT FOR SURFACE ACTIVITY

Sample	Emitter	Activity (Bq cm^{-2})
1.	beta	1,14 ± 0,08
2.	alpha	0,64 ± 0,04
3.	alpha	0,27 ± 0,02
	beta	0,46 ± 0,05

Target values were: 1,21 Bq cm^{-2} for sample 1, 0,71 Bq cm^{-2} for sample 2 and for sample 3 for beta, target value was 0,6 Bq cm^{-2} and for alpha 0,37 Bq cm^{-2}. Results were evaluated as acceptable according to the z-score.

IV. CONCLUSION

This paper presents the results of surface radioactivity contamination measurement done within the inter laboratory proficiency test. This measurement enabled us to see firsthand the advantages and problems that are encountered when conducting surface contamination measurements with handheld instruments. Special attention was committed to the measurement conditions leading to the situation that the values obtained in this proficiency test had good agreement with the target values.

The Effects of X-Radiation in a Quasi-Low-Dropout Voltage Regulator

Vladimir Dj. Vukić

***Abstract*—The aim of this paper was to test the possibility of implementation of the commercial-off-the-shelf (COTS) quasi-low-dropout voltage regulator in a harsh bremsstrahlung environment (in the case of a lifelong exposure to moderate total ionising doses). Results of examination of the LT1086CT5 voltage regulator, performed in the field of X-rays, are presented in this paper. Biased and loaded circuits demonstrated acceptable characteristics in the bremsstrahlung environment for total doses up to 433 Gy, but some samples of unbiased circuits demonstrated unacceptable decline of the output voltage even after absorption of ionising dose of 260 Gy. One-week room temperature annealing led to a further degradation of all of the irradiated voltage regulators, both unbiased and biased, during irradiation. All the examined samples remained functional, but pointed to numerous limitations for implementation of these COTS voltage regulators in an ionising radiation environment.**

***Index Terms*—Voltage regulator; X-rays; bipolar transistor; radiation effects.**

I. Introduction

IMPLEMENTATION of the commercial-off-the-shelf (COTS) integrated circuits, instead of the specially designed "rad-hard" components, is now a long-lasting trend [1]. The main reason is related to the much lower price of the COTS components, as well as the considerably wider portfolio of the available integrated circuit made by the use of modern technological processes [1]. Among the serious candidates for implementation of COTS solutions are power integrated circuits. Low-dropout voltage regulators belong to this class of electronic devices [2]-[5], being particularly important to the point-of-load, low-current power supply of small load (being in the order of several hundred milliamps), as well as the battery powered electronic circuits [6].

In previous years, many efforts were made to examine the possibility of implementation of the COTS low-dropout voltage regulators with various power transistors and control circuit topologies [7]-[9]. Nevertheless, among three different topologies of low-dropout voltage regulators, also one quasi-low-dropout circuit, LT1086CT5, was examined, utilising the NPN power transistor as a pass element [10]. This circuit was a potential candidate for implementation in a moderate radiation environment.

In this paper, examination of characteristics of the LT1086CT5 voltage regulator was presented. Radiation effects caused by total absorbed doses of the braking ionising radiation (bremsstrahlung), up to 433 Gy, were described, followed by a short term 168-hour room temperature annealing.

Vladimir Dj. Vukić is with University of Belgrade, Electrical Engineering Institute "Nikola Tesla", Koste Glavinića 8a, PO Box 139, 11000 Belgrade, Serbia (e-mail: vvukic@ieent.org).

II. Theory

A. Configuration of Low-Dropout Voltage Regulators

One of the basic characteristics for evaluation of voltage regulators is a dropout voltage that is a minimum voltage across a serial (pass) transistor that enables this integrated circuit to maintain a stable voltage on its output terminal [11]. The main difference between configuration of a low-dropout (a) and a quasi-low-dropout (b) voltage regulator is presented in Fig. 1. In a low-dropout voltage regulator, a PNP power transistor may be independent pass element (Qp), so a dropout voltage is equal only to the collector – emitter voltage of a serial transistor [11]. In a quasi-low-dropout voltage regulator, an NPN transistor (Qp1) should be driven by a collector current of accompanying PNP transistor [11] (Qp2). Thus, dropout voltage is now the sum of a PNP driver transistor emitter-base voltage and a serial NPN transistor collector – emitter voltage [11].

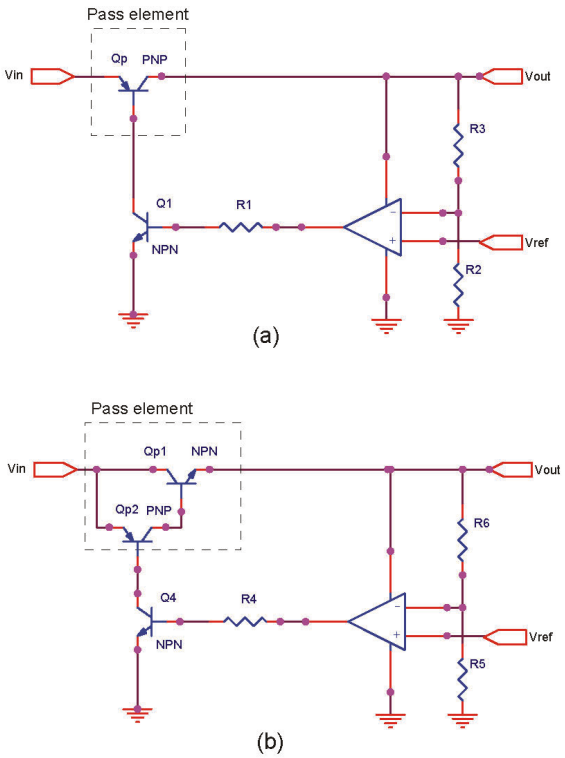

Fig. 1. Topologies of voltage regulators: a) low-dropout; b) quasi-low-dropout.

A negative consequence of implementing a combination of an ordinary PNP and an NPN power transistor as a pass element is primarily related to the increase of a dropout voltage (approximately 1.2-1.5 V for a nominal load, in comparison with approximately 0.6-0.8 V in a case when a PNP power transistor was utilised [11]). On the other hand, the advantage of using an NPN power transistor is related to its operation with much lower base current and, consequently, much lower quiescent current of the entire voltage regulator.

B. Radiation and Post-Irradiation Effects in Bipolar Transistors and Integrated Circuits

The primary effect that ionising radiation has on a bipolar junction transistor is related to the increase of its base current, consequently leading to reduction of the forward emitter current gain [1]. This excess base current is primarily a result of the charge becoming trapped in the isolation oxide and at the semiconductor-oxide interface above the base area [1]. In general form, the relation for the excess base current (ΔI_B) in an irradiated bipolar transistor may be presented as [12]:

$$\Delta I_B = I_B - I_{B0} = \frac{1}{2} q n_i P_E s(N_{ot}, N_{it}, V_{BE}) \gamma(N_{ot}, V_{BE}) e^{\frac{V_{BE}}{2V_T}} \quad (1)$$

where: I_B – base current after irradiation, I_{B0} – base current before irradiation, q – elementary electron charge ($1.6 \cdot 10^{-19}$ C), n_i – intrinsic carrier concentration in silicon, P_E – length of the emitter perimeter, N_{ot} – concentration of the oxide traps, N_{it} – concentration of the interface traps, V_{BE} – voltage on the junction base – emitter, $s(N_{ot}, N_{it}, V_{BE})$ - surface recombination velocity, a function of the specifed electrical values, $\gamma(N_{ot}, V_{BE})$ – an integral describing the depletion region spreading over the intrinsic base [13], and V_T – thermal voltage (26 mV at 20°C).

The other mechanism that primarily affects a PNP bipolar transistor forward emitter current gain is related to similar effects above the emitter area, causing the spread of the base-emitter depletion region deep into the P-type emitter area [14]. Thus, oxide-trapped charge and interface traps above the base and emitter areas are the main cause of the characteristic degradation of a bipolar transistor operating in an ionising radiation environment [14]. Above the P-type area, the effects of the interface and oxide traps are complementary, both leading to degradation of a semiconductor device [14]. Usually, the excess base current of the PNP transistor is considered to be primarily affected by the influence of interface traps [14], while NPN transistors are considered to be mostly affected by the oxide-trapped charge [12]. The following empirical relations are a good illustration of the mentioned phenomena [15]:

$$\Delta I_B \sim N_{it} e^{N_{ot}^2}, \text{ for an NPN transistor} \quad (2)$$

$$\Delta I_B \sim N_{it} \frac{1}{N_{ot}^2}, \text{ for an PNP transistor} \quad (3)$$

Bias conditions also have great impact on the radiation response of a bipolar transistor or integrated circuit based on such an element. While the positive electrical field in the oxide may suppress build-up of the oxide-trapped charge, the negative bias voltage may suppress or even prevent build-up of interface traps [16]. Usually, the most damaging effect may be observed in bipolar transistors and integrated circuits exposed to the influence of ionising radiation without any bias voltage [1]. In these cases, very high excess base currents may be recorded, and both interface traps and the oxide-trapped charge may have great influence on the degradation of a bipolar transistor current gain. On the other hand, operation of the bipolar transistor with high dissipation may significantly reduce its radiation damage and even prevent the integrated circuit failure [3, 9], both due to the high increase of a chip temperature (followed by an annealing of the trapped charge) or operation with high-current-density at the base-emitter area [3].

After the end of ionising radiation exposure, bipolar transistors may demonstrate recovery, or further degradation of their electrical characteristics [1]. Owing to a type of its post-irradiation response, often a trustworthy conclusion may be drawn regarding the mechanism of the bipolar transistor radiation response [1]. The post-irradiation response of an irradiated bipolar transistor is highly temperature dependant. Thus, high temperature annealing may lead to recovery of both oxide-trapped charge (this process becomes more expressed as temperature increases up to 100°C [16, 17]) and interface traps (dominates when temperatures are in the range 150-250°C [17]). Nevertheless, even at a room temperature of nearly 20°C, trapped charge may be recovered, primarily due to the tunnelling mechanism [16]. Thus, room temperature recovery of bipolar transistors is also described by the word "annealing". Recovery of the oxide-trapped charge may be accompanied by further interface trap build-up [18]. In such a case, forward emitter current gain of a bipolar transistor may be additionally reduced. On the other hand, if the oxide-trapped charge had significant influence on the excess base current then the annealing of this charge may lead to an expressed recovery of the forward emitter current gain of an irradiated bipolar transistor.

III. MATERIALS AND METHODS

A. Radiation Source and Dosimetry

The samples of LT1086CT5 voltage regulator, an integrated circuit made by *Linear Technology*®, were tested at the Vinča Institute of Nuclear Sciences, in the Metrology-Dosimetric laboratory. As a source of X-rays, the *Philips*® MG320 dosimetric generator was used. The continuous spectrum of braking radiation was obtained using a voltage of 300 kV and a current of 10 mA, with implementation of a tungsten target. Thus, photon spectrum, with energies up to 300 keV, was obtained [9]. Primary filtration of a photon spectrum was obtained with 4-mm-thick embedded aluminium foil [9]. In order to obtain additional filtration, another 0.47-mm-thick aluminium foil was added [9]. As a result, all the photons with energies lower than 37 keV were removed from the spectrum [19]. Consequently, a bremsstrahlung field was obtained, having a mean energy of 170 keV [9].

Exposure measurement was performed with a cavity ionising chamber *Dosimentor*® PTW M23361 [7]. The DI4 reader was used during the measurement [7]. With these instruments, exposure in Roentgen (R) was procured, and,

recalculated further for the total absorbed dose in silicon-dioxide (Gy(SiO_2)) [9] using X-ray mass attenuation coefficients for air and silicon-dioxide [20]. Using the dosimetric chamber, the exposure rate was measured to be F = 340 R/min = 20,400 R/h. In standard temperature and pressure (STP) dry air, the following relation is valid [17]: 1 R = 0.84 rad(air) = 0.84 cGy(air).

Since the integrated circuit is comprised of the multiple, micrometer-thick layers, only an approximate calculation was made. The kinetic energy of the primary charged particles released by photons, enhanced by the contribution of charged particles travelling through the silicon-dioxide [20], had the crucial influence to the total dose response of bipolar transistors in an integrated circuit. For the nearest available value of the mean photon energy in the table of mass-energy absorption coefficients, that is 150 keV, coefficients were extracted for the air and the silicon-dioxide (borosilicate glass) [20]: $\frac{\mu_{en}}{\rho}(SiO_2) = 2.727 \cdot 10^{-2} \frac{cm^2}{g}$, $\frac{\mu_{en}}{\rho}(air) = 2.496 \cdot 10^{-2} \frac{cm^2}{g}$. According to the available data, the dose rate in silicon-dioxide (reduced to cGy) was calculated as [17, 20]:

$$\frac{dD}{dt}(SiO_2) = F \cdot 0.84 \cdot \frac{\frac{\mu_{en}}{\rho}(SiO_2)}{\frac{\mu_{en}}{\rho}(air)} \quad (4)$$

Finally, total dose rate (in Gy(SiO_2)) was:

$$\frac{dD}{dt}(SiO_2) = 187.2 \frac{Gy}{h} \quad (5)$$

Therefore, in the 170-keV effective X-rays field (V_{TUBE} = 300 kV, I_{TUBE} = 10 mA), dose rate for silicon-dioxide was 187.2 Gy(SiO_2)/h. Measurements were performed after deposition of the following total ionising doses (in Gy(SiO_2)): 0; 43.3; 86.7; 130; 173.3; 260; 346.7; 433. One additional measurement was performed after 168-hour room temperature annealing (without implementation of any bias and load) of the irradiated samples.

B. Electrical Characteristics

Samples of LT1086CT5 voltage regulators were tested in a field of X-rays with two various operating conditions: without bias and load (V_{IN} = 0 V, I_{OUT} = 0 A), as well as with input bias voltage and load current (V_{IN} = 7 V, I_{OUT} = 100 mA) during operation in the ionising radiation environment. In order to enable the voltage regulator operation in the X-rays field, exposed samples were supplied with 10 m long cables [7]. In order to enable remote measurement of the output voltage at the terminals of voltage regulators, the sensing cables of the same length were laid alongside the power supply cables [7]. The power source of DC voltage enabled simultaneous supply up to four electrically isolated integrated circuits [7]. Irradiation of components and measurement were performed at a room temperature of 20°C [7].

Electrical characteristics used for evaluation of the voltage regulator degradation in the X-rays environment were the maximum output current and the minimum dropout voltage. The maximum output current was procured in the measurement point where the voltage regulator input voltage was set to 8 V DC, while the output voltage declined down to 4.7 V (this is a value close to the point when voltage regulator commence the shutdown procedure) [8]. The minimum dropout voltage was obtained for a constant load current of 400 mA and a constant output voltage of 4.9 V [8].

IV. Results

In Fig. 2 were presented variations of the maximum output current in the field of 170-keV X-rays, obtained for unbiased as well as biased and loaded voltage regulators. As initially expected, unbiased circuits demonstrated greater degradation of the maximum output current than the biased ones. So, while biased circuits demonstrated degradation of the maximum output current up to 7 % of the initial value, exposure to X-rays reduced the same parameter in unbiased voltage regulators up to 20 %. However, for a total dose of 433 Gy, such reduction may be acceptable if the integrated circuit kept its functionality as a power source with a stable five-volt output.

Fig. 3. shows the results on variations of the minimum dropout voltage obtained on the same samples of the LT1086CT5 voltage regulator in a bremsstrahlung environment. This test gave much more questioning results regarding this voltage regulator radiation hardness.

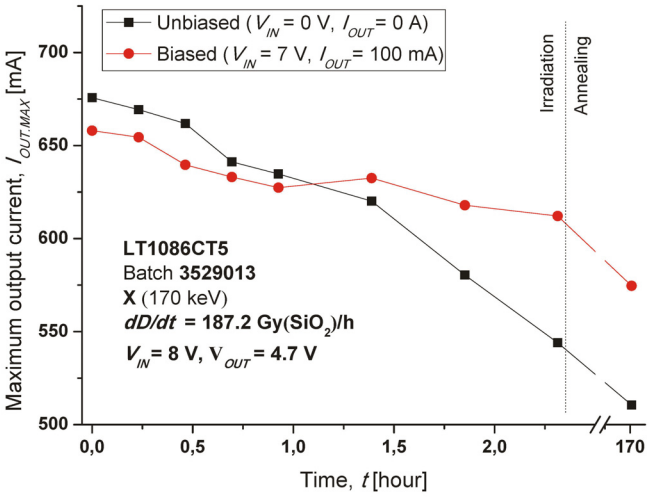

Fig. 2. Change in the maximum output current of LT1086CT5 voltage regulators in the X-rays field.

At first, a comment has to be made regarding the high initial values of the minimum dropout voltage, being approximately 3 V. This relatively high value is a consequence of the low filter capacitance (nominally 330 µF [8]) at the output of the Gretz diode bridge, being a converter of the (transformed) mains AC voltage to a DC voltage at the input terminal of a voltage regulator. Therefore, input voltage on a voltage regulator had a very high AC component affecting the voltage regulator operation, particularly with

high load currents. Nonetheless, such a measurement configuration did not negatively affect procured results on the integrated circuit radiation tolerance.

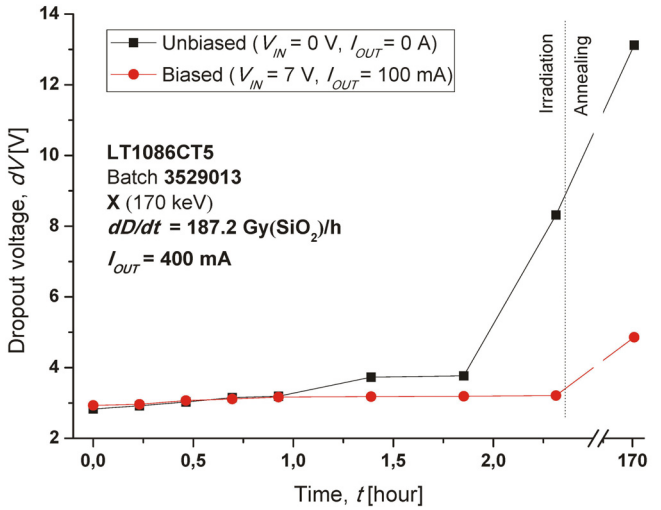

Fig. 3. Change in the minimum dropout voltage of LT1086CT5 voltage regulators in the X-rays field.

The data obtained for unbiased voltage regulators presented in Fig. 3 point to the significant increase of the minimum dropout voltage after deposition of the total dose of 260 Gy. Dropout voltage reached unacceptably high values after the final dose of 433 Gy was achieved. The more careful examination of individual irradiated samples points to the inability of one sample (out of a total of five) to obtain an output voltage of 4.9 V (following absorption of the total dose of 260 Gy). Then, after deposition of 433 Gy, another unbiased sample decreased its output voltage below the mentioned threshold of 4.9 V, bringing the number of unacceptable circuits up to two. Therefore, even to obtain such a reduced voltage, the much higher input voltage had to be applied. Therefore, it led to an increase of the mean value of the minimum dropout voltage of unbiased samples up to 8 V (Fig. 3). It is important to emphasise that none of the biased and loaded samples expressed a similar phenomenon, with all five samples being completely functional, simultaneously having a dropout voltage across a serial transistor being marginally higher from its pre-irradiation value.

V. Discussion

As may be seen from Figs. 2 and 3, in both cases one-week, room temperature isothermal annealing led to a further degradation of irradiated voltage regulators, regardless of their bias conditions during bremsstrahlung exposure. Such a post-irradiation response suggests interface traps as the primary influence on degradation of the critical bipolar transistors. As previously mentioned, physical mechanism that affected the voltage regulator response is related with a partial recovery of the oxide-trapped charge, accompanied by a simultaneous build-up of interface traps. At a first glance, this is a little surprising, since it would be expected that the oxide-trapped charge would have a dominant influence on the serial power NPN transistor. Taking into account the perceived effects, a rise of the power NPN transistor excess base current may be expected, consequently leading to a decline of its forward emitter current gain. Additionally, radiation response of a voltage regulator is not only dictated by a serial power transistor and, furthermore, some small-signal transistors may have a decisive effect on its operation characteristics. It should be brought to mind that, in a quasi-low-dropout voltage regulator, a driver PNP transistor is also a part of the pass element.

Since the photons in bremsstrahlung spectrum contain energies from 37 keV up to 300 keV, there certainly exists possibility for violation of the charged-particle equilibrium (CPE) in the examined integrated circuit. Nonetheless, it was assumed that, looking chip-wide, CPE wouldn't be violated in the active areas of bipolar transistors, situated at the interface Si – SiO_2. Potentially critical areas for the dose enhancement are connections between metallizations and the chip of an integrated circuit [17]. Most of these connections are situated at the bottom of integrated circuit, thus being far away from the active area, right beneath the insulation oxide [17]. Nonetheless, metallizations from the top side of the case, connecting the output leads of voltage regulator with semiconductor, may cause dose enhancement in silicon, if the connection material has a much higher atomic number [16] (in this case, relative to silicon (Si): Z = 14). Usually, metals used for such connections are copper (Cu; Z = 29) or gold (Au; Z = 79). Since the copper doesn't have much higher atomic number than silicon, significant dose enhancement should not be expected. Nonetheless, completely different situation may appear if gold is used. In that case, charged-particle equilibrium may be locally violated. The author did not have insight into the exact material composition of the implemented TO-220 case, used for packaging of the LT1086CT5 voltage regulator. Thus, it was assumed that, chip-wide, for the calculation of the total ionising dose in the insulation layer of SiO_2, CPE was achieved. Nonetheless, it is not impossible that locally, at the connections of some of three output leads with chip, dose enhancement exists. However, it was assumed that the mentioned effect could be distinctively expressed only in some small-signal transistors, and that the serial NPN power transistor is too large to be notably affected by the violation of the CPE.

In general, quasi-low-dropout voltage regulator demonstrated significant sensitivity to the influence of X-rays. A total dose of 260 Gy(SiO_2), being a threshold value when unacceptable degradation was observed in unbiased samples, is lower than expected before the examination. Nonetheless, this was certainly not an example of the extremely low radiation hardness of an analogue integrated circuit. As already presented in the literature [17], threshold of radiation tolerance may vary for several orders of magnitude, depending on the batch of integrated circuit, manufacturer's technological process, bias conditions during the irradiation, as well as the characteristics of the ionising radiation environment (types of spectra, mean photon energy, dose rate,

etc.). The author of this article detected failure of some samples of LM2990T-5 LDO voltage regulators even at the bremsstrahlung total dose as low as 37 Gy(SiO_2) [9], regardless the fact that samples from the same lot in γ-radiation field remained completely functional even after absorption of the total dose of 500 Gy (SiO_2) [9].

In manuals and handbooks may be found approximate data on radiation tolerance of various types of semiconductor devices and integrated circuits. For instance, in the document [21], radiation tolerance of CMOS operational amplifiers (Op Amp) was estimated to be up to 100 Gy [21], while the same parameter for bipolar Op Amps was estimated to be 1 – 2.5 kGy [21]. In the same document, low-dropout voltage regulators were estimated to be radiation tolerant for total ionising doses up to 300 – 500 Gy [21]. Nonetheless, in the same document, there were specified several *National Semiconductor*® regulators, having the stated radiation hardness threshold exceeding 1 kGy [21]. Tolerance to very high total doses of ionising radiation is usually characteristic of the specially designed, rad-hard semiconductor devices and integrated circuits.

The main goal of the research presented in this paper was to examine the possibility of implementation of cheap COTS integrated circuits instead of the very expensive, specially designed rad-hard components. The additional motive for the presented research was the existence of a practically the same component, of the same manufacturer, LT1086MH/883, yet declared for implementation in the harsh radiation environments. According to the performed tests, a conclusion can be made that unbiased LT1086CT5 circuits are not suitable for bremsstrahlung environments where deposition of the total dose greater than 200 Gy(SiO_2) may be expected. Nevertheless, none of the examined circuit demonstrated a functional failure for total ionising doses up to 433 Gy(SiO_2).

Thus, a complex research has to be made, in various radiation fields, prior to qualification of some semiconductor component for exploitation in a radiation environment. In general, implemented technological processes for the synthesis of semiconductor chips (and particular quality of the insulation oxides) dominantly affect the radiation response of an analogue integrated circuit.

VI. Conclusion

Quasi-low-dropout voltage regulators, LT1086CT5, were tested for possibility of implementation in the ionising radiation environment. Regarding these quasi-LDO regulators, for the first time was presented data on the maximum output current and the minimum dropout voltage (recorded with a high load current). Also, results on the one-week, room-temperature annealing are novel data for the irradiated *Linear Technology*® LT1086CT5 COTS voltage regulators.

In the effective 170-keV X-rays field, for a medium dose rate (187.2 Gy(SiO_2)/h), samples of this COTS circuit were tested for two various modes of operation during the exposure: unbiased, as well as with bias and load (V_{IN} = 7 V, I_{OUT} = 100 mA). For the total ionising dose of 433 Gy(SiO_2), biased samples demonstrated higher radiation tolerance than the unbiased. Nevertheless, the maximum output current recorded in unbiased samples of LT1086CT5 voltage regulators did not fall below 80 % of their pre-irradiation values. Less acceptable were the values of the minimum dropout voltage (for I_{OUT} = 400 mA), particularly due to a decline of the output voltage below the minimum acceptable value of 4.9 V, recorded on some of the tested samples. Also, cause for concern was further degradation of electrical parameters used in all the tested circuits (regardless of their bias conditions during irradiation), noticed during the following room temperature, one-week isothermal annealing sequence. Experimental results support the conclusion that unbiased LT1086CT5 voltage regulators are not suitable for bremsstrahlung environments where lifelong absorption of the total dose greater than 200 Gy(SiO_2) may be expected. Nonetheless, recorded radiation response leaves a possibility that these voltage regulators may be satisfactory exploited in the radiation environment as continuously biased circuits, operating with load currents being, for an order of magnitude, lower than the voltage regulator nominal output current.

Procured results could not lead to an unambiguous conclusion on the radiation tolerance of these COTS voltage regulators. Presented results were related only to a medium–photon-energy bremsstrahlung field, and for two types of operating conditions. Thus, it was not sufficient to make a final conclusion on the possibility to implement this analogue integrated circuit in all kinds of ionising radiation environments. Therefore, in order to get a complete insight into this circuit's ionising radiation hardness, it would be necessary to perform also its detailed examination in the field of γ-radiation, with more different bias and load conditions, as well as for total ionising doses exceeding 433 Gy(SiO_2). Finally, only separation of radiation effects in small-signal transistors, on the one hand, and the power transistor, on the other, could enable the precise identification of the failure mechanisms of a quasi-low-dropout voltage regulator LT1086CT5, affected by the influence of an ionising radiation environment.

Start-up Approach and Proposal for Nuclear Safety Knowledge Management Strategy in the Republic of Serbia

Koviljka Stankovic, *Member, IEEE*

***Abstract*— The aim of this paper is to present the start-up approach and proposal for nuclear safety knowledge management strategy in the Republic of Serbia. The main role in maintaining and protecting existing nuclear knowledge has been taken by academic staff. In order to share nuclear safety knowledge, university teachers started with implementation of bilateral agreements on professional and technical cooperation between respective institutions. The main goals of such cooperation, but not limited to, are effective solving of problems that are met in practice at professional level as well as involving students in real nuclear safety practice. It should be pointed out that the initiators of such coordination are highly educated young professionals (in science and engineering) who have been well trained through international training courses. That way of cooperation could be suitable starting point for straightening approach and developing long-term nuclear knowledge safety strategy at national level.**

***Index Terms*— nuclear safety, knowledge management, strategy, public opinion.**

I. Introduction

KNOWLEDGE management (KM) consists of three fundamental components: people, processes and technology (PPT sheme). KM focuses on people and organizational culture to stimulate and nurture the sharing and use of knowledge; on processes or methods to find, create, capture and share knowledge; and on technology to store and make knowledge accessible and to allow people to work together without being together. People are the most important component, because managing knowledge depends upon people's willingness to share and reuse knowledge [1-5].

Nuclear knowledge management (NKM) is knowledge management as applied in the nuclear technology field. It supports the gathering and sharing of new knowledge and the updating of the existing knowledge base. Knowledge management is of particular importance in the nuclear sector, owing to the rapid development and complexity of nuclear technologies and their hazards and security implications. The International Atomic Energy Agency (IAEA) launched a nuclear knowledge management programme in 2002 [6].

Concerns about global climate change and the availability of economically exploitable fossil fuels are driving many countries to reconsider the use of nuclear energy. Yet, the innovations required to design, construct, operate and maintain nuclear power plants consistent with international needs and constraints must derive from a strong foundation of well-sustained nuclear knowledge [7].

It is probable that nuclear knowledge will continue to expand and change. Without diligence in managing nuclear knowledge, substantial portions of it could be lost due to personnel retirements and the likelihood that much of it could be disused or discarded as a result of either negligence or changing priorities. It will be as important to identify and properly treat obsolete, superseded knowledge as it will be to gather and share new knowledge. It is therefore necessary to maintain effective and efficient KM systems. NKM has become an increasingly important element of the nuclear sector in recent years, resulting from a number of challenges and trends [8]:

- Countries with expanding nuclear programmes require skilled and trained human resources to design and operate future nuclear installations. Capacity building through training and education and transferring knowledge from centres of knowledge to centres of growth are key issues.
- In countries with stagnating nuclear programmes, the challenge is to secure the human resources needed to sustain the safe operation of existing installations, including their decommissioning and related programmes for spent fuel and waste. Replacing retiring staff and attracting the young generation to a career in the nuclear field are key challenges.
- Non-power applications of nuclear technologies require a stable or even growing base of nuclear knowledge and trained human resources, be it for cancer treatment or for food and agriculture. This need is present in all States using nuclear technologies, independent of the use of nuclear power.

Nuclear safety knowledge management (NSKM) includes the safety of nuclear instalations, radiation safety, the safety of radioactive waste management and safety in the transport of radioactive materials for the protection of people and the environment against radiation risk and for safety of faciliteies and activities that give rise to radiation risks, under normal circumstances or as a concequence of incidents [9].

This paper is focuses on current situation at national level in the field of nuclear knowledge. The majority of data presented, author said at Technical Meeting on Managing

Koviljka Stanković is with the Faculty of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: kstankovic@etf.bg.ac.rs).

Nuclear Safety Knowledge - National Approaches and Experience held in IAEA Vienna from 17 July to 21 July, 2017.

II. BACKGROUND FACTS

The Republic of Serbia is a landlocked country situated at the crossroads of Central and Southeast Europe and the central Balkans. Serbia numbers around 7 million residents. Its capital, Belgrade, ranks among the oldest and largest cities in Southeast Europe. During the breakup of Yugoslavia in 1990s, Serbia formed a union with Montenegro which dissolved peacefully in 2006, when Serbia reestablished its independence.

In golden age of Nuclear Sciences, in early1950s, the Faculty of Electrical Engineering at University of Belgrade introduced the Nuclear engineering graduate program. Up to early 1990s Faculty of Electrical Engineering produced majority of personnel and scientist who has been working at Vinca Institute of Nuclear Sciences. The Vinca Institute was established in 1948, in the same time as Faculty of Electrical Engineering did. Vinca Institute of nuclear sciences was, at that time, the most significant research institution at national level and still is. Vinca have had two research reactors, RA and RB. The first one was shouted down before former Yugoslavia adopted moratorium on Nuclear Power uses in 1989. The other one, RB is zero power research reactor and operated until 2012 when the license expired.

The Vinca Institute had been splited in two parts in 2009 when the Government established the Public Company Nuclear Facillities of Serbia. Both reactors instalations together with radiactive waste storages became properties of Nuclear Facillities of Serbia. Currently, Reactor RA is in the process of decommisioning. In the same year, 2009, the Government established the national regulatory body – Serbian Radiation Protection and Nuclear Safety Agency. The first low on ionizing radiation was adopted in 2011. That low has been replaced with newly introduced Low on radiation and nuclear safety and security in 2018 [10]. In complianse with this Low the national regulatory body became independant body, so Serbia has been approaching condition met in developed countries.

From 1990s, applications of ionizing radiation can be studied at almost all state universities, mainly through undergraduate and graduate programs on Biomedical and environmental engineering and Medical physics at: University of Belgrade (Faculty of Electrical Engineering, Faculty of Physics, and Physical Chemistry), University of Novi Sad (Faculty of Technical Sciencies and Faculty of Physics), University of Kragujevac (Faculty of Physics), University of Nis (Faculty of Electronic Engineering, Faculty of Physics), University of Kosovska Mitrovica (Faculty of Physics).

Nowadays, the Faculty of Electrical Engineering (Univ. of Belgrade) retained the core of the subjects from the period before the 1990s, such as Nuclear Physics, Nuclear Technique and Dosimetry and Radiation Protection, and thus remained unique in the field of education in nuclear science and radiation protection at national level. There is a clear tendency in changing orientation in education from the period of moratorium adoption, so all faculties direct education in the field of radiation physics and technology that does not include nuclear power. At present, university programs that has retained the study of nuclear technology are master program for Biomedical and Environmental Engineering and doctoral program for Nuclear, Medical and Environmental Eng. both at the Faculty of Electrical Engineering, University of Belgrade.

It is interesting to point out that the Faculty of Electrical Engineering reintroduced the following courses in 2011: Neutron Physics, Nuclear Power Engineering and Application of Radioisotopes in Industry through the master program on Biomedical and Environmental eng. For the period of last seven years, the course on Nuclear Power Engineering has been followed by 230 students.

III. EMIGRATION AND AGEING

Migraton (or mobility) of competent personel has, in general, a positive impact in knowledge share. In our specific case, starting from 1990s and up to this date The Republic of Serbia suffers the emigration of well-educated and competent personel, since the period of the state trasition is long lasting and causes the brain drain effect. From the other hand, older generation of experts undergone the proces of retirement, so the number of people involved in the field of nuclear scieces rapidly drops down. Problem is more expressed by taking in account senior experts, regarded as “singletons”, being retired with having no immediate successors [1]. It is easily to conclude that Serbia already lost all generations older than 50 in the field of nuclear sciences.

IV. CURRENT SITUATION

A. People and Buliding the Competence

People involved in field of nuclear and radiation safety are mostly of age between 30 and 45. All young professionals employed by operators, regulators and R&D organizations acquired fundamental and applicative education at respective state universities. Majority of them permanently participate in international training courses, mainly in those organized by IAEA. In that sence, our young professionals are well - educated to understand and apply safety culture and the systemic approach to nuclear safety as well as to cope with technology changes.

For junior employees the training course that is exceptionally important and useful for building the competence is IAEA PGEC - Postgraduate Educational Course in Radiation Protection and the Safety of Radiation Sources [11]. Beside having a formal education, the IAEA PGEC gives the technical, operational and legal knowledge, self-confidence, capability to share knowledge, to promote safety culture and to build informal regional network of young professionals.

B. Communities of Practices

Professional associations that deals with nuclear/radiological safety at national and/or regional level

are:

- Society for Radiation Protection of Serbia and Montenegro is sucssesor of The Yugoslav Society for Radiation Protection (founded in 1963). The society acts as a professional non-profit organization that is oriented to improve the safety of people and the environment from harmful effects of radiation. The main activity of the society is to support the organization of research in all fields of application and use of radiation sources, and to encourage and monitor the highest professional and ethical principles in the course of this research. The society actively influence the writing of the proposal for the regulation of radiation protection at the national level, working with other professional societies and associations in the field of radiation protection in other countries and with international organizations and associations. Every second year the society organises symposium. Symposia proceedings are implemented in IAEA database (http://dzz.org.rs).
- The oldest and the most prestigious Serbian professional society in the field of technical sciences is ETRAN (E - Electronics, T - Telecommunications, R - Computing, A – Automatics, N - Nuclear Technologies). This professional association of engineers and nuclear scientists was established in 1953 as non-governmental and non-profit organization. Conferences are held annually and supported by IEEE (https://www.etran.rs). The Nuclear Section of the ETRAN has been strongly binded to the Nuclear Society of Serbia (http://nss.vinca.rs). Nuclear Society of Serbia has been in the phase of inactivity for last few years.

There are few societies related to Health Care such as: Society of radiology and nuclear medicine technicians (https://radteh.org.rs), Society of Nuclear medicine (www.unms.rs), Society of Medical Physics, Association of Clinical Engineers the Republic of Serbia (http://www.akis.rs), Society of medical oncologists of Serbia (umos.org.rs) etc.

C. Coordination mechanisms and Level of integration between institutions

International documents that deals with the nuclear safety knowledge management suggest that the government should take the main role in forming the strategy for nuclear safety knowledge management. That is an ideal situation, easily applicable in developed counties.

As in case of Serbia, the main role in maintaining and protecting existing nuclear knowledge has been taken by academic staff. In order to share nuclear safety knowledge, university teachers started with implementation of bilateral agreements on professional and technical cooperation between respective institutions. It should be pointed out that the initiators of such coordination are highly educated young professionals (in science and engineering) who have been well trained through IAEA PGEC and other Agency's training courses. The example of good practice is agreement between Faculty of Electrical Engineering (Univ. of Belgrade) with Public Company Nuclear Facilities of Serbia, as well as with Radiation and Environmental Protection Department of the Vinca Institute of Nuclear Sciences. Those agreements established the solid bases for BSc, MSc and PhD students education, professional and scientific collaboration among staff within these institutions in the field of nuclear sciences and radiation protection. The main goals of such cooperation, but not limited to, are effective solving of problems that are met in practice at professional level as well as involving students in real nuclear safety practice. Some results of such cooperation are traditionally published through conferences organised by the Society for Radiation Protection of Serbia and Montenegro and ETRAN society. This should be used as suitable starting point for integration between institutions in Serbia as well as for straightening approach and developing long-term nuclear knowledge safety strategy at national level, supervised by national regulatory body. Benefit of such approach can be realized in terms of efficiency (cost) savings.

The suggested approach by the author was presented at Technical Meeting on Managing Nuclear Safety Knowledge - National Approaches and Experience held in IAEA Vienna from 17 July to 21 July, 2017. The approach has been evaluated by IAEA, in still unpublished TECDOC report, as following: In Serbia, which faces the challenges of ageing of human resources and emigration, the University of Belgrade proposed a unique approach for national nuclear safety knowledge management, via coordination mechanisms among relevant institutions, Communities of Practice (CoP) and building competences. A new strategy for knowledge management is envisaged, for which the established Communities of Practice of young professionals could be a starting point [9].

D. Proposal for Creating a Strategy for NSKM

The proposal for creating the national strategy for NSKM should consist following successive steps:

- Orientation – where the knowledge is? Starting points: university collaboration with industry and/or regulatory body as well as with communities of practices helps to define the orientation of NSKM with cost savings.
- Strategy formulations – to consolidate initial ideas on current and further needs at national level.
- Design and launch – to define clear methodology for specific plans, timed plan of the tasks as well as IT platform for creating a formal network. At this point, national regulatory body should take the key role.
- Expand and support - KM is a long lasting process and it should be harmonized, by time to time, with national specific strategies.

E. Coping with Societal Occasions and Public Acceptance of Radiation

Accidents occurred during history are the main reason for anti-nuclear organizations in preventing global use of nuclear energy. Two accidents in history have dominantly influenced the change of national policies regarding the application of nuclear energy, as well as the change in the opinion of the public about the application of this energy source. These are the Accident in Chernobyl, which took place on April 26,

1986, and the Fukushima Accident on March 11, 2011. Following the Fukushima Accident, the acceptance of nuclear energy by public opinion has diminished to a historical minimum. Shortly after this event, the European Union in 2012 published a Communication "Energy Roadmap by 2050" [12]. With this document, the Commission proposed a transformation of the energy sector with a reduction in greenhouse gas emissions by 2050, to 80 to 95% below the emission level in 1990. Such a scenario can not be achieved without the use of nuclear energy. Serbia also envisioned the possibility of using nuclear energy to reduce the greenhouse effect in a document published in 2015 [13]. After all, nuclear fission is the second-largest world's low-carbon electricity source after hydroelectric power. Given the growing need for electricity, it can be concluded that civilization is entering the era of "nuclear renaissance". However, without public acceptance, the future of nuclear energy is uncertain.

Serbia is also specific in this respect, since public opinion forms an attitude of ionizing radiation on a completely different basis. Namely, the decisive influence on the shaping the opinion on the nuclear energy application has depleted uranium. After the NATO “intervention” in the territory of Serbia in 1999, the influence of media and the few medical doctors contributed to the fact that almost entire population in Serbia, regardless of the level of formal education, believes that the predominant causative agens of the “cancer epidemia” is basically depleted uranium. So, we are facing the consequences of false results promotion performed by few individuals and their followers [14].

Scientific facts, the knowledge that technical and medical staff wants to transfer to the population, as well as publications intended for the general auditorium, such as Ref. [14], can not change the attitude of the population about the complete mystification of depleted uranium.

In such an environment, it is much easier to educate young generations than adults. For the education of the youth and for raising awareness about nuclear energy, we have a good national example in the region, which is Slovenia [15]. The students of the Faculty of Electrical Engineering in 2012 visited the Slovenian Educational Center.

In terms of adult education, there are huge problems in front of us, so we have to face the first challenge - education of journalists, and then all other population groups in Serbia. So, shaping the public opinion on nuclear energy is still questionable point.

V. CONCLUSION

The paper presented the start-up approach and proposal for nuclear safety knowledge management in the Republic of Serbia. The main role in NSKM at national level should be taken by the university and research staff since they have obligations to follow new trends in the field and to work permanently on implementation in university studies programs. University collaboration with operators, R&D organisations and communities of practice should be used as suitable starting point for integration between institutions in Serbia as well as for straightening approach and developing long-term nuclear knowledge safety strategy at national level, all supervised by national regulatory body. Benefit of such approach can be realized in terms of efficiency (cost) savings. Each institution has its own knowledge tradition, so relevant institutions should be kept together through the nuclear safety knowledge management in order to create and develop both the national memories and national investment for the future.

Karakterizacija moderatora detektora brzih neutrona primenom Monte Carlo simulacije

Jovana Knežević, Miloš Vujisić

***Apstrakt*—U radu je, pomoću Monte Carlo metode, izvršena simulacija odziva detektora brzih neutrona sa Bonner-ovim sferama, odnosno proračun efikasnosti detekcije u zavisnosti od energije upadnih neutrona u rasponu od 10^{-8} MeV do 10^{2} MeV, uzimajući u obzir različite prečnike moderatorske sfere (od 2 do 12 inča), kao i različite materijale moderatora: polietilen i parafin. Simulacija je izvršena pomoću kôda razvijenog u softverskom paketu MATLAB. U fizičke modele neutronskih interakcija uvedene su aproksimacije koje omogućavaju efikasnije izvršavanje razvijenog kôda. Rezultati dobijeni na ovaj način poređeni su sa rezultatima datim u literaturi, dobijenim detaljnijim modelom.**

***Ključne reči*—detekcija brzih neutrona; elastično rasejanje; Bonner-ove sfere; moderator; Monte Carlo; MATLAB.**

I. Uvod

Neutronsko zračenje predstavlja čestično, nenaelektrisano jonizujuće zračenje koje potiče iz jezgra, iz kog se emituje pri raspadu spontanom fisijom ili u nuklearnim reakcijama. U prirodne izvore neutronskog zračenja spada kosmičko zračenje, gde neutroni nastaju u nuklearnim reakcijama primarnog kosmičkog zračenja sa jezgrima gasova u gornjim slojevima atmosfere, pri čemu se neutroni oslobađaju procesom kaskadnih nuklearnih reakcija i raspada i kao sekundarno kosmičko zračenje dospevaju na Zemlju. U veštačke izvore neutrona, za primene u nauci, tehnologiji materijala i industriji, spadaju istraživački nuklearni reaktori, nuklearni generatori i prenosivi izvori. U raznim neutronskim poljima sreću se neutroni sa energijama u širokom opsegu, od nekoliko eV do nekoliko desetina MeV. U Tabeli I je data klasifikacija neutrona u zavisnosti od energije [1].

TABELA I
PODELA NEUTRONA PO ENERGIJAMA

Hladni neutroni	< 0,001 eV
Termički neutroni	0,001 – 0,5 eV
Epitermički neutroni	0,5 – 500 eV
Intermedijarni neutroni	0,5 – 100 keV
Brzi neutroni	0,1 – 10 MeV
Ultra brzi neutroni	> 10 MeV

Jovana Knežević – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar Kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: jovanadknezevic@yahoo.com); istraživanje podržalo Javno preduzeće „Nuklearni objekti Srbije“, Mike Petrovića Alasa 12-14, 11351 Vinča, Beograd, Srbija

Miloš Vujisić – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar Kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: vujsa@etf.rs).

Zbog elektroneutralnosti, neutron pri interakciji sa materijalnom sredinom gotovo ne reaguje sa elektronskim omotačem atoma, već direktno sa jezgrom. Neutroni ne osećaju odbojnu kulonovsku silu jezgra, pa su u stanju da izazovu nuklearne reakcije i pri veoma niskim energijama.

Neutronske interakcije, na kojim se zasniva i njihova detekcija, mogu se podeliti na rasejanja i apsorpcije, kao što je predstavljeno u Tabeli II.

TABELA II
TIPOVI INTERAKCIJA NEUTRONA I JEZGRA

Rasejanje	Elastično rasejanje	Potencijalno
		Rezonantno
	Neelastično rasejanje	Na nivoima
		Na kontinuumu
Apsorpcija	Reakcije sa emisijom više neutrona	
	Reakcije sa emisijom drugih čestica	
	Fisija	

Materijali koji se koriste za detekciju neutrona najčešće predstavljaju kombinaciju onih koji pretvaraju neutrone u sekundarne naelektrisane čestice i poznatih detektora ovih naelektrisanih čestica. U zavisnosti od energije (brzine) upadnih neutrona, detektori se mogu klasifikovati u detektore sporih neutrona i detektore brzih neutrona. Detekcija sporih neutrona se bazira na nuklearnim reakcijama pri kojima se neutroni konvertuju u naelektrisane čestice koje se direktno identifikuju jonizacionim komorama, scintilacionim brojačima i slično.

Kod detekcije brzih neutrona, prvo se vrši usporavanje neutrona do energija koje odgovaraju sporim neutronima, a zatim se mehanizam detekcije odvija po postupku za detekciju sporih neutrona. Materijal koji usporava neutrone se naziva moderator. Na njemu se neutroni usporavaju reakcijom elastičnog rasejanja, pa se za moderator bira onaj materijal koji ima veliku verovatnoću za elastično rasejanje. Najčešći materijali koji se koriste za moderaciju su stoga laka i teška voda, grafit, polietilen, parafin i drugi.

Nuklearne reakcije pogodne za detekciju sporih neutrona su: $^{10}B(n,\alpha)^{7}Li$, $^{6}Li(n,\alpha)^{3}H$, $^{3}He(n,p)^{3}H$, kao i fisija nuklida ^{233}U, ^{235}U i ^{239}Pu sporim neutronima. U materijale koji se koriste za detektore sporih neutrona ubrajaju se gasni proporcionalni brojač punjen bor tri fluoridom BF_3, scintilacioni detektor od litijum jodida aktiviranog

europijumom LiI(Eu), proporcionalni brojač punjen gasom helijuma ^{3}He i drugi.

Najčešće korišćen detektor na bazi moderacije neutrona danas predstavlja detektor sa Bonner-ovom sferom. Konfiguracija detektora sa Bonner-ovom sferom podrazumeva moderatorsku sferu u čijem se centru nalazi mali sferični ili cilindrični detektor [3,4].

II. Opis Monte Carlo simulacije

Monte Carlo metoda predstavlja statističku tehniku uzorkovanja koja se uspešno primenjuje u raznovrsnim naučnim disciplinama. Interakcije koje određuju istoriju svakog pojedinačnog neutrona koji se prati modeluju se probabilističkim zakonima. Metoda je razvijena sredinom dvadesetog veka i prvenstveno je korišćena za istraživanje ponašanja neutronskih lančanih reakcija u fisionim uređajima.

Monte Carlo simulacija transporta neutrona za potrebe istraživanja u ovom radu sprovodi se u nekoliko koraka.

Najpre se uzorkuje pravac upadnog neutrona. Ukoliko se razmatra izotropno polje neutrona kome je izložen detektor na bazi Bonner-ovih sfera, na slučajan način se uzorkuju parovi tačaka na površini moderatorske sfere. Tetiva koja spaja te dve tačke predstavlja pravac upadnog neutrona.

Zatim se određuje mesto interakcije neutrona, pretpostavljajući da čestica ulazi u prostor sastavljen od dva regiona (moderatorske sfere i detektora) od homogenog materijala, od kojih je svaki okarakterisan makroskopskim efikasnim presekom za interakciju.

Posle mesta interakcije potrebno je odrediti na kom se atomu materijala dogodila interakcija. Nakon odabira jezgra, vrši se izbor interakcije na tom jezgru. Neutron će putem apsorpcije nestati sa verovatnoćom $\frac{\sigma_a}{\sigma_t}$, gde je σ_a mikroskopski efikasni presek za apsorpciju, a σ_t totalni mikroskopski efikasni presek. Ostale interakcije su reakcije rasejanja, u koje spadaju elastično i neelastično rasejanje [2].

Izbor elastičnog rasejanja se vrši u skladu sa verovatnoćom $\frac{\sigma_{el}}{\sigma_t-\sigma_a}$. Dalji koraci za modelovanje su:

1. Izabere se slučajan broj ξ_1
2. Odredi se kosinus ugla rasejanja u sistemu centra mase preko $cos\theta^{CM} = 1 - 2\xi_1$
3. Odredi se kosinus ugla rasejanja u laboratorijskom sistemu preko $cos\theta = \frac{1+Acos\theta^{CM}}{\sqrt{1+2Acos\theta^{CM}+A^2}}$
4. Odredi se kinetička energija neutrona nakon rasejanja $E_n' = E_n \frac{1+2Acos\theta^{CM}+A^2}{(A+1)^2}$
5. Izabere se drugi slučajni broj ξ_2
6. Odredi se azimutalni ugao u laboratorijskom sistemu preko $\varphi = 2\pi\xi_2$
7. Isporuče se φ, θ, E_n'.

Simulacija neelastičnog rasejanja na nivoima se vrši kroz sledeće korake:

1. Izabere se slučajan broj ξ_1
2. U slučaju izotropnog neelastičnog rasejanja u sistemu centra mase, određuje se $cos\theta^{CM} = 1 - 2\xi_1$
3. Određuje se $B = \sqrt{A^2 + QA\frac{A+1}{E_n}}$, gde vrednost $-Q$ određuje eksitacionu energiju jezgra
4. Određuje se ugao rasejanja u laboratorijskom sistemu preko $cos\theta = \frac{1+Bcos\theta^{CM}}{\sqrt{1+2Bcos\theta^{CM}+B^2}}$
5. Izračunava se kinetička energija neutrona nakon rasejanja kao $E_n' = E_n \frac{1+2Bcos\theta^{CM}+B^2}{(A+1)^2}$
6. Izabere se drugi slučajni broj ξ_2
7. Odredi se azimutalni ugao u laboratorijskom sistemu preko $\varphi = 2\pi\xi_2$
8. Isporuče se φ, θ, E_n'.

III. Rezultati simulacija i diskusija

U svrhu ovog numeričkog eksperimenta razvijen je MATLAB kôd pomoću kog je izvršena simulacija odziva detektora sa Bonner-ovom sferom Monte Carlo metodom. Geometrija problema uključuje sfere različitih prečnika (od 2 do 12 inča) koje se nalaze u izotropnom polju neutrona. Pored toga, izvršena je i varijacija materijala moderatorske sfere. Uzeti su u obzir polietilen i parafin. Detektor je scintilacioni kristal LiI(Eu), sferne geometrije, prečnika 4 mm. Centar moderatorske sfere se poklapa sa centrom detektora. U Tabeli III dati su osnovni podaci za materijale moderatorske sfere i detektora, koji su korišćeni prilikom Monte Carlo proračuna.

TABELA III
Osnovni podaci o materijalu moderatora i detektora

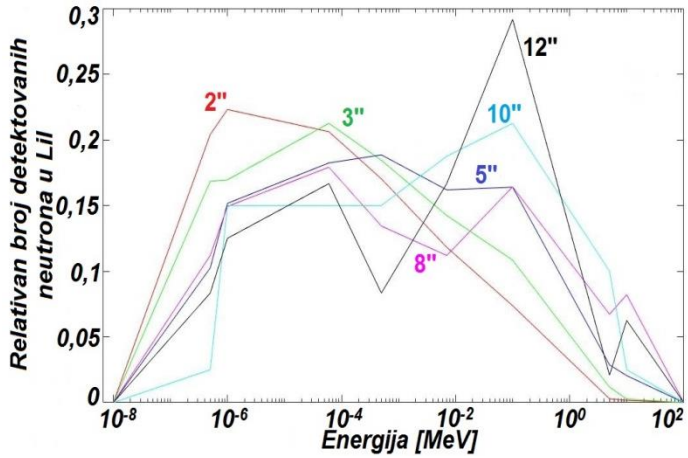
Materijal	Polietilen	Parafin	Litijum jodid (detektor)
Hemijska formula	CH_2	$C_{30}H_{62}$	LiI(Eu)
Molarna masa [g/mol]	14	422	133
Gustina [g/cm^3]	0,95	0,87	4,08

Izotropno neutronsko polje je simulirano slučajnim izborom parova tačaka na moderatorskoj sferi, gde tetiva koja spaja jedan par tačaka čini prvobitni pravac inicijalnog neutrona. Simulacija je izvršena za 500 000 istorija čestica, sa 11 diskretnih tačaka za energiju u rasponu od 10^{-8} MeV do 10^2 MeV za svaku česticu.

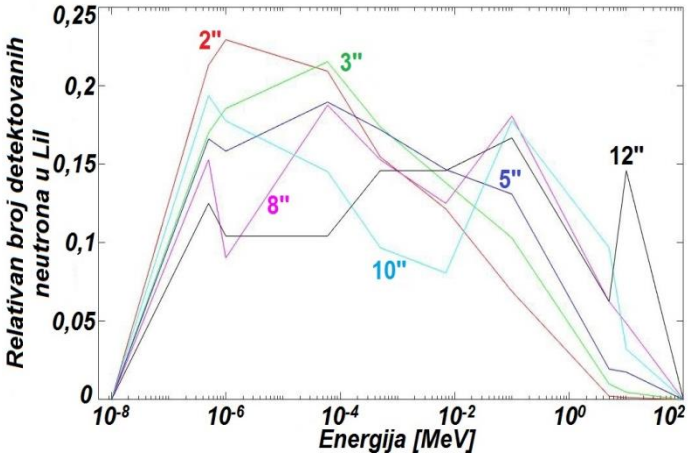
Podaci za mikroskopske efikasne preseke uzeti su iz biblioteke podataka ENDF/B-VII [5]. Razvijen MATLAB kôd se oslanja na podatke za eksperimentalno određene preseke koji opisuju interakciju neutrona sa jezgrom, za

energije neutrona niže od 20 MeV. Za neutrone energija preko 20 MeV ne postoji dovoljno podataka za preseke za interakciju, pa se stoga koriste nuklearni modeli (intranuklearna kaskada i evaporacioni modeli) u okviru Monte Carlo metode. Proračuni funkcije odziva Bonner-ove sfere pomoću Monte Carlo metode i nuklearnih modela mogu smanjiti pouzdanost, posebno pri energijama neutrona većim od 20 MeV.

Na slikama 1 i 2 dat je grafički prikaz rezultata simulacija odziva detektora, u vidu energetskih zavisnosti efikasnosti detekcije, koja je računata kao relativni broj detektovanih neutrona, za dva ispitivana materijala i za različite prečnike moderatorske sfere.



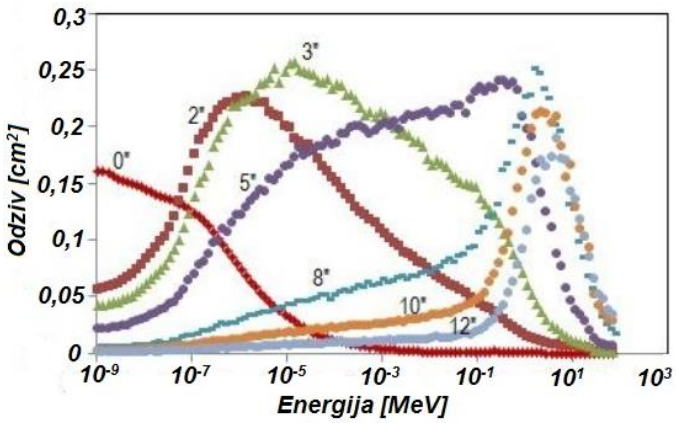
Sl.1. Poređenje efikasnosti detektora sa Bonner-ovim sferama različitih prečnika, materijal sfere je polietilen



Sl.2. Poređenje efikasnosti detektora sa Bonner-ovim sferama različitih prečnika, materijal sfere je parafin

Kriterijumi za okončanje istorije u simulacijama bili su: prag energije neutrona do kog se neutron prati (0,025 eV), apsorpcija unutar moderatorske sfere i izlazak neutrona iz moderatorske sfere. Smatra se da je neutron detektovan unutar scintilacionog kristala LiI ako je doživeo reakciju apsorpcije na jezgru ^{6}Li. Navedeni kriterijumi okončanja istorije i aproksimacije koje sadrži razvijeni MATLAB kôd daju relativno grube procene rezultata kada se dobijeni grafici porede sa graficima koji su nastali simulacijama nekih od detaljnijih modela iz literature [7,8,9].

Dobijeni rezultati mogu da se uporede sa rezultatima u radu [6], u kom je sprovedena simulacija izlaganja Bonner-ovih sfera (istih prečnika kao u ovom radu) neutronskom izvoru oblika diska, sa 10^{9} istorija i 111 diskretnih tačaka za energiju u rasponu od 10^{-9} MeV do 10^{2} MeV. Geometrija scintilacionog detektora LiI(Eu) je cilindrična. Navedena studija je za simulaciju transporta zračenja koristila softverski paket MCNP (Monte Carlo N-Particle). Odziv detektora sa Bonner-ovim sferama različitih prečnika, sa polietilenom kao materijalom moderatora, koji se može naći u [6], dat je na slici Sl.3. U navedenom radu je takođe izvršena simulacija odziva za sferu prečnika 0 inča, što odgovara detektoru bez moderatora, za koji oblik funkcije odziva direktno odražava mikroskopski presek za (n,α) reakciju na ^{6}Li.



Sl.3. Funkcija odziva Bonner-ovih sfera dobijena pomoću softverskog paketa MCNP [6]

Konfiguracija moderatora je najčešće sferna, kako bi se dobio izotropan odziv detektora. Za sfere malih dimenzija, stepen moderacije je mali, kao i zahvat termičkih neutrona unutar moderatora. Zbog toga, niskoenergetski neutroni imaju veliku verovatnoću da dođu do scintilacionog LiI kristala i da budu detektovani, a brzi neutroni uspevaju da umaknu iz moderatora. Kod sfera velikih dimenzija veći je i stepen moderacije, odnosno verovatnoća da će brzi neutroni biti usporeni pri elastičnim rasejanjima na jezgrima moderatorskog materijala. Takođe je veća i verovatnoća apsorpcije termičkih neutrona u moderatoru, pre nego što dospeju do detektora. Stoga su upravo neutroni visokih energija ti koji će prevashodno biti detektovani u LiI detektoru. Može se zaključiti da je za male dimenzije Bonner-ove sfere efikasnost detekcije veća za neutrone nižih energija, dok je za sfere većih prečnika efikasnost detekcije veća za visokoenergetske neutrone. Zbog toga se maksimumi efikasnosti detekcije pomeraju ka višim energijama, kako prečnik moderatorske sfere raste.

Sa grafika prikazanog na Sl.1, za sfere prečnika od 2 do 12 inča, glavne razlike su primećene u oblastima koje odgovaraju niskim energijama neutrona i u oblastima koje odgovaraju energijama preko 20 MeV. Funkcije odziva za sfere sa prečnicima od 2, 3 i 5 inča su značajne za oblast od 10^{-8} MeV do 10^{-3} MeV, odnosno za termičke i epitermičke neutrone. U opsegu od 10^{-2} MeV do 10^{2} MeV dominantne su funkcije

odziva sfera prečnika 8, 10 i 12 inča. Za sfere prečnika 2 i 3 inča oblici funkcije su međusobno slični i uticaj mikroskopskog efikasnog preseka za (n,α) reakciju na ^{6}Li polako postaje neznatan. U oblasti niskih energija, uočava se da dominira funkcija odziva sfere prečnika 2 inča u odnosu na prečnike od 3 i 5 inča, a vrednost maksimuma se nalazi u opsegu od 0,2 do 0,25. Dalje se može primetiti kako sa porastom dimenzija sfera efikasnost detekcije ima tendenciju opadanja za termičke i epitemičke neutrone, a maksimumi se pomeraju ka višim energijama. Maksimumi funkcije odziva za sfere od 5 i 8 inča imaju približne vrednosti, ali se oni ne nalaze u istom užem energetskom opsegu. Uočava se značajan porast relativnog broja detektovanih neutrona za sferu prečnika 12 inča koji dostiže vrednost nešto ispod 0,3 u oblasti energija oko 10^{-1} MeV, u odnosu na maksimume funkcija odziva za druge prečnike sfere moderatora.

Prema rezultatima prikazanim na Sl.2 takođe se može primetiti dominantnost funkcija odziva za sfere prečnika 2, 3 i 5 inča u oblasti niskih energija od 10^{-8} MeV do 10^{-3} MeV, i za sfere prečnika 8, 10 i 12 inča u visokoenergetskoj oblasti od 10^{-2} MeV do 10^{2} MeV. Funkcija ima sličan oblik za sfere prečnika od 2, 3 i 5 inča u oblasti niskih energija, gde se maksimum funkcije za sferu od 2 inča ističe u odnosu na funkcije odziva sfera od 3 i 5 inča i vrednost maksimuma se nalazi u opsegu od 0,2 do 0,25. Efikasnost detekcije zatim opada kako rastu energija neutrona, za ove tri sfere. U oblasti visokih energija neutrona, funkcije odziva sfera od 8, 10 i 12 inča dobijaju na značaju. Primećuje se da se maksimumi funkcija odziva ove tri sfere nalaze u energetskoj oblasti oko 10^{-1} MeV, gde je vrednost maksimuma najveća za sferu od 8 inča i nalazi se u opsegu od 0,15 do 0,2. Takođe, uzimajući u obzir maksimalne vrednosti relativnog broja detektovanih neutrona za sve sfere, uočava se da je najveća efikasnost detekcije za sferu prečnika 2 inča.

Ukoliko se izvrši poređenje dva grafika efikasnosti detekcije u zavisnosti od energije neutrona, dobijene za različite materijale moderatora, vidi se da u oblasti energija od 10^{-8} MeV do 10^{-3} MeV relativan broj detektovanih neutrona za sfere manjih dimenzija za parafin dostiže veće maksimalne vrednosti nego za polietilen. Za oblasti energija od 10^{-2} MeV do 10^{2} MeV maksimumi funkcije odziva imaju veće vrednosti za sfere većih dimenzija za polietilen u odnosu na parafin. Ukoliko se uzme u obzir kompletan grafički prikaz, primećuje se da se maksimalna vrednost efikasnosti detekcije dobija za polietilen, za sferu najvećih dimenzija u visokoenergetskom opsegu. Za parafin se maksimalna vrednost efikasnosti detekcije dobija za sferu najmanjih dimenzija u niskoenergetskom opsegu. Ako se posmatraju energije neutrona, može se reći da za visokoenergetske neutrone, bolju efikasnost detekcije ima moderatorska sfera većih dimenzija napravljena od polietilena. Za niskoenergetske neutrone, veću efikasnost detekcije ima moderatorska sfera manjih dimenzija napravljena od parafina.

Svi dobijeni rezultati pokazuju znatno slaganje sa rezultatima na Sl.3, dobijenim detaljnijim modelima neutronskih reakcija u paketu MCNP. S druge strane, za očekivati je da se kôd razvijen za aktuelno ispitivanje, koji je opisan u odeljku II, izvršava brže i na slabijim računarskim platformama od onih koje često zahteva MCNP, što je prednost kada je potrebno izvršiti niz ispitivanja odziva detektora sa raznim geometrijskim konfiguracijama i različitim materijalma moderatora i osetljive zapremine.

IV. ZAKLJUČAK

Cilj rada je razmatranje odziva detektora sa Bonner-ovom sferom u zavisnosti od energije upadnih neutrona, uzimajući u obzir različite prečnike i materijale moderatorske sfere. Analiza je sprovedena Monte Carlo simulacijom transporta neutrona kôdom razvijenim u softverskom paketu MATLAB.

Sa dobijenih grafika prikazanih na Sl.1 i Sl.2 može se uočiti da krive efikasnosti detekcije za sfere manjih dimenzija dostižu maksimume u energetskim oblastima od 10^{-8} MeV do 10^{-3} MeV. Kako prečnik sfere raste, tako se maksimumi krive efikasnosti detekcije pomeraju ka višim energijama neutrona, a maksimumi se nalaze u oblasti energija oko 10^{-1} MeV. Najveća vrednost relativnog broja detektovanih neutrona za polietilen ima sfera od 12 inča, dok za parafin ima sfera od 2 inča.

Moderatorska sfera od polietilena ima veću efikasnost detekcije za visokoenergetske neutrone u odnosu na parafinsku sferu, a parafin daje dobar odziv za niskoenergetske neutrone ukoliko se koristi sfera manjih dimenzija. Uzimajući u obzir hemijske formule polietilena (CH_2) i parafina ($C_{30}H_{62}$), ovo zapažanje se može pripisati manjem stepenu moderacije parafina zbog prisustva većeg broja atoma ugljenika u parafinu kao i manje gustine u odnosu na polietilen.

ZAHVALNICA

Ovaj rad je podržan od strane Javnog preduzeća „Nuklearni objekti Srbije“ i Ministarstva prosvete, nauke i tehnološkog razvoja u okviru projekta br. 171007.

ABSTRACT

In this paper, using the Monte Carlo method, a simulation of the response of fast neutron detectors with Bonner spheres has been performed, in terms of detection efficiency dependence on neutron energy in the range from 10^{-8} MeV up to 10^{2} MeV, taking into account different diameters of the moderator sphere (from 2 to 12 inch), as well as various moderator materials: polyethylene and paraffin. The simulation was conducted using a code developed for this purpose in the MATLAB software package. Approximations have been introduced to the physical models of neutron interactions that enable more efficient code execution. Results obtained in this manner are compared to the results obtained by a more detailed model, found in literature.

Characterization of fast-neutron detector moderators based on Monte Carlo simulation

Uloga Pavla Savića u otkriću fisije

Dragoslav Nikezić

***Apstrakt*—U ovom radu je opisano otkriće nuklearne fisije i uloga Pavla Savića u tom procesu. Dve istraživačke grupe, jedna u Berlinu i druga u Parizu, su ulagale ogromne napore ka dobijanju transuranskih elemenata. Ozračivan je uran u nadi da će niz beta minus raspada dovesti do stvaranja elemenata sa atomskim brojem većim od 92, ali je to ozračivanje dovodilo do fisije. Mnogobrojne poteškoće su dovodile do pogrešnih zaključaka što je otežalo razumevanje stvarnih procesa u ozračenom uranu.**

***Ključne reči* — Fisija, transuranski elementi, neutron, lantanoidi**

I. UVOD

Pošto je na Prirodno matematčkom fakultetu u Kragujevcu. 2019. godina proglašena godinom Pavla Savića, autor ovog rada je našao za shodno da se detaljnije osvetli njegova uloga u otkriću fisije. Otkriće fisije je posledica intenzivnih napora ka sintetizovanju transuranskih elemenata u periodu od 1934. godine do 1939. godine. Istorija ovog otkrića je detaljno opisana u većem broju publikacija [1],[2],[3].

Dve istraživačke grupe su se naročito istakle velikim radom i aktivnošću na ovom polju, jedna u Berlinu, koju su činili Otto Hahn, Fritz Strassmann i Lisa Meitner, i druga u Parizu, Irena Joliot Cuiri i Pavle Savić. Otkriće fisije je pratilo niz zabluda, pogrešnih tumačenja eksperimentalnih rezultata, čak i kad je objašnjenje bili skoro očigledno, kao i kontraverze oko dodele Nobelove Nagrade.

Sama reč "fisija" znači cepanje jezgra i u užem smislu podrazumeva se cepanje teških jezgara u dva nejednaka fragmenta posle zahvata neutrona. Cepanje jezgra se može odigrati na veći broj načina, tako da se u komadu urana ozračenog neutronima nalazi veliki broj različitih izotopa. Fisija je otkrivena na tri najteža elementa u prirodi, Th, Pa i U.

U periodu pre drugog svetskog rata nije postojala spektroskopija, te je identifikacija izotopa radjena na osnovu vremena poluraspada. Aktivnost izotopa je merena Gajger Milerovim brojačima. Poznato je da aktivnost svakog radioizotopa opada eksponencijalno sa vremenom; u logaritamskoj skali kriva raspada se pretvara u pravu čiji je koeficijenat pravca povezan sa konstantom radioaktivnog raspada, tj., sa vremenom poluraspada. Ovakav metod identifikacije izotopa je vrlo komplikovan i verovatno netačan u slučaju smeše većeg broja različitih izotopa, što se inače dobija pri fisiji. Problem identifikacije izotopa dobijenih u komadu urana izloženog neutronima, je jednim delom doprineo teškom otkrivanju fisije. Umesto gama spektroskopije, za identifikciju izotopa primenjivane su hemijske metode ekstrakcije, tzv. višestruka frakciona kristalizacija, posle čega je mereno njihovo vreme poluraspada.

Godine 1932. otkriven je neutron, mada je njegovo postojanje pretpostavio Raderford 12 godina pre eksperimentalne potvrde. Medjutim, Raderfordova pretpostavka je bila potpuno zaboravljena. Otkriće neutrona su pratile mnogobrojne teškoće i kontraverze, po pitanju nejasnoće dobijenih eksperimentalnih podataka.

Otkrićem neutrona eksperimentalni fizičari su dobili sredstvo kojim su mogli da bombarduju atome i na niskim energijama. Neutron je neutralan i lako može da udje u pozitivno naelektrisano jezgro, jer ne oseća električno polje naelektrisanih čestica kao u slučaju alfa čestice ili protona.

Enriko Fermi je prvi uvideo mogućnosti koje pružaju neutroni i krenuo je sa sistematskim ozračivanjem poznatih elemenata. Nije našao nikave nove nuklearne reakcije sve do fluora, F. Dobijena reakcija na fluoru ga je ohrabrila da nastavi rad sve do najtežeg elementa urana. Dobio je povećanje aktivnosti urana posle ozračivanja (uran je prirodna radioaktivan, ali je njegova aktivnost mala), i sasvim slučajno je otkrio da se efekat pojačava ako se umesto brzih, koriste spori neutroni. E. Fermi je u suštini proizveo fisiju u komadu urana, ali nije prepoznao značaj dobijenih rezultata. Rezultati koje je dobijao Fermi su bili kontradiktorni. Za svoj rad Fermi je dobio Nobelovu Nagradu 1938., a posle toga je napustio Italiju. U Italiji je u tom periodu narastao fašizam, a njegova supruga je bila jevrejskog porekla.

U to vreme pažnja istraživača je bila zaokupljena otkrićem transuranskih elemenata, tj., elemenata sa atomskim brojevima većim od 92. Fermi je dao sledeće smernice koje su bile potpuno pogrešne: *prva je bila da nuklearne reakcije izazivaju samo male promene jezgra*. Druga je da *svi elementi sa atomskim brojevima većim od urana (transurani) treba da budu slični elementima treće grupe prelaznih metala, Re, Os, Ir i Pt jer se nalaze u grupama periodnog sistema ovih elemenata*. U to vreme nije bilo poznato da postoje aktinidi i da svi imaju slične hemijske osobine, jer se popunjava unutrašnja 5f podljuska. Ove dve zablude su imale velikog uticaja na kasniji rad istraživača u ovoj oblasti, jer su uporno pokušavali da dobiju transurane, koji bi bili slični Re, Os, Ir i Pt. Čak su im dali i imena ekaRe, ekaOs, ekaIr i sl. Pored ovih zabluda, istraživače je zbunjivalo i to što su količine dobijenih elemenata vrlo male. Nisu znali da se fisija proizvodi na izotopu ^{235}U koji u ukupnom uranu učestvuje svega sa 0.72%.

Dve, ranije pomenute grupe, u Parizu i Berlinu su naročito intenzivno nastavile rad na dobijanju transuranskih elemenata.

Dragoslav Nikezić – Prirodno-matematički fakultet, Univerzitet u Kragujevcu, R. Domanovića 12, 34000 Kragujevac (e-mail nikezic@kg.ac.rs).

II. RAD GRUPE U BERLINU

Fermi je ranije dobio četiri beta emitujuće materije u uranu ozračenom neutronima sa vremenima poluraspada 10 s, 40 s, 13 min i 90 min. Grupa u Berlinu je ubrzo našla deset aktivnosti, dok su Cuiri i Savić našli osam aktivnosti u reakciji neutron-torijum. Hemijska analiza je obavljana rastvaranjem ozračenog urana u kiselinama, i hemijskom separacijom. Problem je bio mala količina stvorenih elemenata. Obe grupe su bile ubedjene da se ozračivanjem stvaraju transuranski elementi i da su analogni trećoj grupi prelaznih metala Re, Os, Ir, Ot, kako je to Fermi sugerisao. Zbog toga je korišćen renijum za taloženje radioaktivnih produkata u obliku sulfida. Ovaj način taloženja je bio problematičan jer je zajedno sa željenim, taložio i brojne druge elemente. Ovo je bila stranputica u istraživanjima izazvana pogrešnim zaključcima autoriteta Fermija. Drugi glavni eksperimentalni problem je bio nagomilavanje produkata raspada koji su preplavili male iznose novo formiranih produkata.

Takodje, obe grupe su smatrale da se neutron-uran reakcija odigrava na ^{238}U zbog njegove velike obilnosti u prirodnom uranu od 99.275 %. Tek 1939. godine, kada je shvaćeno da se radi o fisiji, prepoznato je da je fisibilan ^{235}U sa izotopskom obilnošću od svega 0.72 %. Ovim se objašnjava dobijanje vrlo malih količina novo proizvedenih izotopa. Značajan problem su i relativno kratka vremena poluraspada pojedinih izotopa (npr 10 s) što je onemogućavalo radiohemijsku analizu. Zbog toga je pažnja usmerena na radioaktivne elemente koji su dugoživeći i koje je moguće (bez obzira na minimalne dobijene količine) ipak analizirati radiohemijski.

Obe grupe su imale izuzetne eksperimentalne poteškoće.

Broj novodobijenih vremena poluraspada, tj., broj novodobijenih radioizotopa, se povećavao i to je dodatno komplikovalo analizu. Rasla je kompleksnost problema.

Hahn, Meitner i Strassmann (hemičar analitičar) su publikovali brojne radove u perodu 1935. do 1938. godine, izveštavajući o novo dobijenim aktivnostima i poboljšavajući podatke i eksperimentalne tehnike. U tim publikacijama često su menjali vremena poluraspada, identifikovali nova. Bili su čvrsto ubedjeni da se radi o transuranskim elementima i da su oni slični elementima treće grupe prelaznih metala. Razvili su niz šema raspada, i dali imena „novo otkrivenim“ elementima (pomenuta ranije). Grupa u Berlinu je bila sigurna u sledeće šeme raspada

$$n+{}_{92}U \rightarrow {}^{10s}_{92}U \xrightarrow{\beta} {}^{2.2\,\mathrm{min}}Eka_{93}\mathrm{Re} \xrightarrow{\beta} {}^{59\,\mathrm{min}}Eka_{94}Os \xrightarrow{\beta} {}^{66h}Eka_{95}Ir \xrightarrow{\beta} {}^{2.25h}Eka_{93}Pt \xrightarrow{\beta} Eka_{97}Au$$

$$n+{}_{92}U \rightarrow {}^{40s}_{92}U \xrightarrow{\beta} {}^{2.2\,\mathrm{min}}Eka_{93}\mathrm{Re} \xrightarrow{\beta} {}^{55.7h}Eka_{94}Os \xrightarrow{\beta} Eka_{95}Ir$$

$$n+{}_{92}U \rightarrow {}^{23\,\mathrm{min}}_{92}U \xrightarrow{\beta} Eka_{93}\mathrm{Re}$$

Postavljene su i druge hipoteze u vezi sa izomerizmom pojedinih elemenata, što je bilo poznato kao moguće. Izomerija je pojava da jedan izotop ima više vremena poluraspada. Prethodne šeme su bile u potpunosti pogrešne, kao i tumačenja oko izomerije.

U jednoj situaciji Hahn je obavio ozračivanje urana neutronima u toku od 80 dana. Ovakvo ozračivanje je moglo da proizvede dovoljnu količinu neptunijuma i plutonijuma, i da dovede do otkrića prva dva transurana. Nadjen je izotop sa vremenom poluraspada od 60 dana, ali nije nastavljen rad u ovom smeru.

U tom periodu došlo je do jakog porasta nacizma u Nemačkoj. Lisa Meitner je imala jevrejsko poreklo i uspela je da napusti Nemačku. Dospela je do Švedske tj., Štokholma gde nije imala skoro ničega ni za život ni za rad. Obrela se u laboratoriji Seighbahna.

U jednom periodu Hahn i Lisa su nastavili saradnju, eksperimenti su sprovodjeni prema Lisinim predlozima, i imali su više zajedničkih publikacija. Medjutim, koautorstvo je prekinuto, jer je sada Hahn bio u opasnosti zbog publikovanja sa jevrejskom kolegenicom.

III. RAD GRUPE U PARIZU

Grupa u Parizu. Irena i Pavle su radili na sličan način kao i u grupa u Berlinu. Oni su, 1935. u neutron-torijum reakciji našli četiri aktivnosti, koje su kasnije Hahn i Meitner povećali na šest. Od 1937. god. Irena i Pavle su počeli eksperimente ozračivanja urana neutronima. Ubrzo su našli aktivnost koja je opadala sa vremenom poluraspada od 3.5 h (koju Hahn i Meitner nisu nalazili). Za razliku od H&M, Pavle i Irena su koristili lantan kao nosilac. Lantan je izabran jer se u periodnom sistemu nalazi u istoj grupi kao i aktinijum, Ac.

Primenjujući frakcionu kristalizaciju Irena i Pavle su prvo sugerisali da je elemenat sa vremenom poluraspada od 3.5 h Aktinijum. Ponovo su obavili frakcionu kristalizaciju produkta očekujući da će se novodobijeni izotop odvojiti od lantana, ali se to nije desilo. Aktivnost je ostala sa lantanom, pri čemu Ac nije. Prvobitna pretpostavka da aktivnost od 3.5 h potiče od aktinijuma Ac, su ubrzo odbacili. Slika iz originalnog rada Cuiri i Savića je data na Slici 1.

Irena i Pavle su bili vrlo blizu otkriću fisije, jer su u eksperimentu zaista dobili lantan, zbog čega i nisu mogli da ga odvoje od lantana, koji su koristili kao nosač. Lantan je jedan od značajnih fisionih produkata i javlja se u više različitih izotopa u fisionoj smeši. I ova grupa je bila pod uticajem Fermijeve ideje da se dobijaju transurani ili elementi koji su blizu urana u periodnom sistemu. Ipak su ustvrdili da interpretacija rezulata stvara mnogobrojne teškoće. Publikovali su dva rada [4], [5]:

Ovo je prva jasna naznaka o dobijanju elemenata iz sredine periodnog sistema. I pored toga, nikom nije palo na pamet da dolazi do cepanja jezgra urana. Bilo je neshvatljivo da neutron energije reda 1 eV može da izazove raspad velikog jezgra urana koje ima 238 nukleona. Smatralo se da ako dolazi do cepanja jezgra, produkti cepanja moraju da tuneluju Coulumb-ovu potencijalnu barijeru, što je spor proces.

Grupa iz Berlina nije verovala ovim rezultatima, i Hahn je te rezultate komentarisao kao zbrku, neljubaznost i profesionalnu ljubomoru: produkt od 3.5 h je nazvao kuriozitetom. Hahn i Meitner su pisali Ireni Cuiri, sugerišući da je podatak o izotopu sa vremenom poluraspada 3.5 h pogrešan i da je potrebno da povuku publikovani rad. Rasla je napetost izmedju ovih dveju grupa i konačno je Hahn zamolio

Frederika da zaustavi Irenu i Savića u publikovanju rezultata koji pobijaju njegove i Meitnerove rezultate.

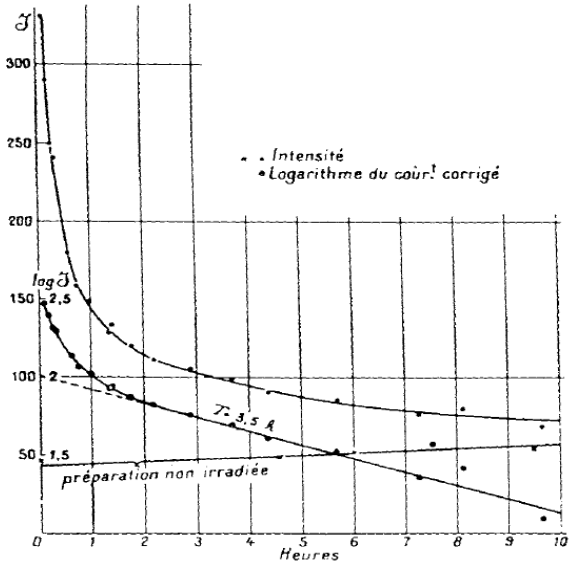

Fig. 8. The 3.5-h activity found in uranium irradiated by neutrons and measured directly as published by *I. Curie* and *P. Savitch* [86] in Paris, July 1938. Upper curve: activity measured with the sample covered by a copper foil of 0.48 g · cm^{-2} thickness, depicted linearly as a function of time; lower curve: build-up of natural decay products in uranium, also depicted linearly; middle curve: difference between the two measurements in semilogarithmic representation with 16-min "eka-rhenium" at the beginning followed by a pure decay with 3.5 h half-life.

Sl. 1. Slika iz originalnog rada Irene Cuiri i Pavla Savića. Rad je publikovan u Julu 1938. Gronja kriva: izmerena aktivnost uzorka pokrivenog sa bakarnom folijom debljine 0.48 g·cm^2 u linearnoj zavisnosti od vremena; donja kriva: nagomilavanje produkata prirodnog raspada urana, takodje prikazano linearno; srednja kriva: razlika izmedju dva merenja u semilogaritamskoj prezentaciji sa 16 min „eka-renijuma" na početku koji prati čist beta raspad sa 3.5 h poluraspada.

Produkt od 3.5 h se nikako nije mogao uklopiti u šeme transformacija koje su razvili Hahn i Strasman.

Cuiri i Savic su čak razmatrali mogućnost stvaranja lakših elemenata posle ozračivanja urana neutronima. Irena je jednom prilikom izjavila "*čini mi se da imamo ceo periodni sistem u ozračenom uranu*".

Hahn i Strassman su ubrzo publikovali rad tvrdeći da se posle ozračivanja urana neutronima dobija 16 različitih elemenata sa atomskim brojevima od 88 (Ra) do 90 (Th) i od 92 (U) do 96. Opet se vidi jak uticaj Fermijevih preporuka.

IV. FISIJA KONAČNO

Irena i Pavle su sa sigurnočću tvrdili da se formiraju transurani, kao i izotopi lakši od urana, ali bliski uranu po atomskom broju. Cuiri i Savić su hemijskom procedurom dobili produkt koji prati lantan (Z=57). Hahn i Strassmann (iako se nisu slagali sa rezultatima Cuiri i Savića) su ponovili postupak hemijske separacije, ali su umesto lantana koristili barijum. Barijum se u periodnom sistemu nalazi u istoj grupi kao i radijum, Ra. Dobili su produkt koji prati barijum (Z=56). Pretpostavili su (opet pogrešno) da su to izotopi radijuma Ra.

Ni jedni ni drugi nisu novodobijene rezultate prepoznali kao lantan ili barijum.

Do ove tačke, obe grupe su bile praktično na istom nivou u pogledu eksperimentalnog rada, ali i nerazumevanja stvarnih procesa, koji se dogadjaju ozračivanjem urana. Činjenica je da su Irena i Pavle prvi našli elemente iz sredine periodnog sistema, ali sami nisu verovali u svoj rezultat. Bolje rečeno, nisu bili u stanju da objasne dobijene rezultate, kao i grupa u Berlinu. Hahn i Strasman, kao i Irena i Pavle i dalje su sumnjali u rezultate dobijene dobrim eksperimentalnim radom. Svega mesec dana kasnije Hahn i Strassmann su bili sasvim sigurni da se barijumovi izotopi stvaraju nakon ozračivanja urana i torijuma. Pored toga nadjeni su i drugi fisioni produkti Sr, Y, Kr ili Xe, koji budući da su beta minus radioaktivni stvaraju Cs i Rb.

Grupa iz Pariza je na ovom mestu zaostala u "fotofinišu trke ka otkrićem fisije".

U Hahnovom pismu Lisi Meitner iz 19.12.1938. Hahn je pisao „*naš izotop radijuma se ne ponaša uopšte kao radijum već kao barijum. Možda ti (Lisa) možeš da daš neko fantastično objašnjenje. Mi shvatamo da uran ne može da sagori i pretvori se u barijum"*.

Tri dana kasnije, **22.12.1938**. Hahn i Strasman podnose rad koji je publikovan 1939. u Januaru. Hahn je insistirao na brzom publikovanju, a s obzirom da je bio vrlo uticajan, rad je izašao u roku od samo mesec dana [6].

U ovom radu Hahn i Strassmann su napisali

"*As chemists we really ought to revise the decay scheme given above and insert the symbols, Ba, La, Ce, in place of Ra, Ac, Th. However, as ''nuclear chemists'' working very close to the field of physics, we cannot bring ourselves yet to take such a drastic step which goes against all previous experience in nuclear physics. There could perhaps be a series of unusual coincidences which has given us false indications.*"

"Kao hemičari, zaista treba da preuredimo naše šeme raspada i da pišemo simbole Ba, La, Ce umesto Ra, Ac i Th. Medjutim, kao nuklearni hemičar, radeći vrlo blizu fizici, ne možemo da preduzmemo tako drastični korak, koji se protivi celokupnom prethodnom iskustvu u nuklearnoj fizici. Moguće je da je neki niz neobičnih slučajnosti doveo do pogrešne indikacije. "

Ovaj rad se smatra otkrićem fisije za koje su Hahn i Strassmann nagradjeni Nobelovom nagradom za hemiju 1944. (Drugi svetski rat je još uvek trajao u svoj svojoj žestini i pored imena Hahn i Strassmann, stoji Treći Rajh).

Lisa Meitner nije bila koautor na tom radu. Nije ni do sada sasvim jasno da li je ova sigurnost u stvaranju lakih elemenata njihova originalna ideja, ili je proistekla iz diskusije sa Lisom Meitner i poredjenjem sa rezultatima Irene Cuiri i Pavla Savića. Radovi Cuiri- Savić su citirani u tom radu, čime je priznat njihov odlučujući doprinos.

V. OBJAŠNJENJE EKSPERIMENTALNIH REZULTATA I SAME FISIJE

Hahn se više puta obraćao Lisi Meitner za pomoć u objašnjenju dobijenih eksperimentalnih rezultata. U tom periodu Lisa je bila u Štokholmu gde se našla sa svojim

rodjakom Otto Frishom (takodje fizičar, sestrić). Otto Friš je radio u Institutu za teorijsku fiziku Kopenhagenu u Danskoj.

U diskusiji Friš i Lisa su došli do zaključka da se radi o cepanju jezgra urana. Diskusija je vodjena katoličkog Božića 25.12.1938. u toku njihove šetnje po snegu u Švedskoj

Otto Friš se setio modela jezgra koji se popularno zove model tečne kapi- predložen od strane Gamova i Bohra. Jezgro je po nekim svojim osobinama slično tečnoj kapi i ovaj model može da objasni neke osobine jezgra. Ako kap tečnosti (npr, voda) perturbiramo, može doći do njenog raspadanja na više manjih kapljica. Ova analogija je poslužila Otto Frišu i Lisi Meitner za objašnjenje mnogobrojnih eksperimentalnih rezultata. Ispravno su pretpostavili da nakon apsorpcije neutrona od strane jezgra urana, jezgro postaje nestabilno, deformiše se i formiraju se dva entiteta. Konačno odbojna Kulonova sila nadjača privlačnu nuklearnu silu (koja drži nukleone na okupu u jezgru) i jezgro se podeli u dva lakša. Velika energija od oko 200 MeV, koja potiče iz različitih energija veze urana i fisionih produkata prema $E=mc^2$, se oslobadja kroz kinetičku energiju fisionih produkata. Za objašnjenje fisije nije potrebna kvantna mehanika, odnosno tunel efekat kojim se objašnjava alfa raspad. Takodje su shvatili da ako je jedan produkt Ba(Z=56) drugi mora biti Kr(Z=36) , 36+56=92 tj U(Z=92). Objašnjenje je kasnije poboljšano činjenicom da se pri zahvatu neutrona jezgrom ^{235}U oslobodi energija vezivanja koja je za oko 0.5 MeV veća od visine Coulumbove barijere, te zato nije potrebno tunelovanje.

Lisa Meitner u koautorstvu sa Otto Frischom je u radu podnetom u **16.01.1939**. upotrebila reč „**fisija**“. Rad je publikovan u časopisu Nature [7]

Abstrakt rada je sledeći

*It seems therefore possible that the uranium nucleus has only small stability of form, and may, after neutron capture, divide itself into two nuclei of roughly equal size (the precise ratio of sizes depending on finer structural features and perhaps partly on chance). These two nuclei will repel each other and should gain a total kinetic energy of c. 200 MeV, calculated from nuclear radius and charge. This amount of energy may actually be expected to be avaiable from the difference in packing fraction between uranium and the elements in the middle of the periodic system. The whole '**fission**' process can thus be described in an essentially classical way, without having to consider quantum-mechanical 'tunnel effects', which would actually be extremely small, on account of the large masses involved.*

University, Copenhagen.

Slobodan prevod ovog, genijalno napisanog apstrakta je: *Čini se da jezgro urana ima neku formu male stabilnosti i može se posle zahvata neutrona podeliti u dva jezgra približno iste veličine (tačan odnos veličina zavisi od fine strukture i možda delimično od šanse). Ova dva jezgra se odbijaju i dobijaju kinetičku energiju oko 200 MeV, izračunato iz nuklearnog radijusa i naelektrisanja. Ovaj iznos energije se može očekivati iz razlike energije veze po nukleonu izmedju urana i elemenata iz sredine periodnog sistema. Ceo proces fisije se tako može opisati na klasičan način, bez razmatranja kvantno-mehaničkog tunel efekta, koji bi trebalo da je ekstremno mali s obzirom na velike mase koje učestvuju u procesu.*

U medjuvremenu Hahn i Strassman podnose još jedan rad u kome se u naslovu pominje reč fisija [8]. Ovaj rad je publikovan pre rada Maitner-Frish na zahtev Otta Hahna za brzim publikovanjem.

VI. ZAKLJUČAK

Put ka shvatanju da je cepanje jezgra urana moguće je trajao skoro pet godina. U tom periodu dve grupe, u Parizu i Berlinu su slepo verovale preporukama, koje je dao Fermi i koje su bile pogrešne. Irena Cuiri i Pavle Savić su prvi došli do saznanja da se u ozračenom uranu nalazi *lantan*, element iz sredine periodnog sistema. Hahn i Strassmann su ponovili njihov rad, ali sa *barijumom* kao nosiocem, i našli su veći broj elemenata iz sredine periodnog sistema. Krajnje objašnjenje procesa fisije dali su Lisa Meitner i Otto Frish.

Nobelovu Nagradu za hemiju dobili su Hahn i Strassman. Lisa Meitner nije dobila Nobelovu Nagradu, ali je transuranski element sa atomskim brojem 109 imenovan po njoj. Otto Frish nije dobio ni jedno priznanje sličnog značaja. Najveći gubitnici su Irena Cuiri i Pavle Savić, koji su bili na korak od otkrića fisije. Nedodeljivanje bar dela Nobelove Nagrade ovoj grupi se može tumačiti i time što je Irena Cuiri već dobila jednu Nobelovu Nagradu za otkriće veštačke radioaktivnosti.

Pored ovih dvaju grupa, postojale su i druge istraživačke grupe koje su ispustile ovo i još neka značajna otkrića u ovoj oblasti fizike.

Posle otkrića fisije, usledila je čitava lavina radova o karakteristikama fisije, od kojih su neki bili veoma značajni. Krajnji rezultati otkrića fisije su: konstrukcija nuklearnih reaktora, nuklearna energetika, proizvodnja nuklearnog oružja, otkriće velikog broja beta minus radioaktivnih izotopa koji se veoma mnogo koriste u medicini (Tc, Lu, Y, Mo i dr) i industriji.

ABSTRACT

Discovery of fission and role of Pavle Savić is described in this paper.

Discovery of fission and role of Pavle Savić

Dragoslav Nikezić

Preliminarni pregled početaka jugoslovenskog nuklearnog programa

Maja Korolija, *Istraživač-pripravnik, Institut za multidisciplinarna istraživanja, Beograd*

***Apstrakt*—Namera je da se u radu ukratko prikaže početak jugoslovenskog nuklearnog programa. U radu se ispituju kako specifičnosti konteksta Hladnog rata, tako i uloga i primena nauke, prvenstveno nuklearne fizike, u tom periodu. U radu se analizira geopolitički položaj FNRJ nakon prekida saradnje sa SSSR-om 1948. godine i fokus jugoslovenskog političkog vrha na razvoj nuklearnog programa, uz prikaz osnovnih podataka o institutima u kojima se on sprovodio. U ovom kontekstu prikazuje se dinamika odnosa između predstavnika vlasti i naučnika, i razmatra se značaj tih odnosa za jugoslovenski nuklearni program.**

Ključne reči — FNRJ; Hladni rat; Nuklearni program

Iz srca atoma rodiće se besklasno društvo.
Marko Ristić

NAUKA U KONTEKSTU HLADNOG RATA

Tek što se Drugi svetski rat završio, a konstantno odmeravanje snaga između dva nekadašnja saveznika u borbi protiv sila Osovine - SAD-a i SSSR-a - već je uzelo maha. Konfrontacija ove dve svetske sile dovela je do polarizacije država u svetu na dva sukobljena tabora. Ova situacija koja je potpuno dominirala svetskom političkom scenom druge polovine dvadesetog veka predstavljala je novu vrstu rata poznatog kao – Hladni rat (Hobsbaum 2002).

> „Kako je vreme prolazilo, bilo je sve više stvari koje su mogle da pođu pogrešno, i političkih i tehnoloških, u stalnoj nuklearnoj konfrontaciji koja se zasnivala na pretpostavci da jedino strah od „uzajamno zajamčenog uništenja“ (što je pravilno zgusnuto u akronim MAD (igra reči, na engleskom znači „lud“ prim. prev.) može sprečiti jednu ili drugu stranu da ne da stalno spreman signal za planirano samoubistvo civilizacije“ [Hobsbaum 2002: 174].

Prvi put u istoriji odvijao se sukob dva vojna bloka, naoružana nuklearnim raketama i taktičkim oružjem koje je u stanju da uništi čitavu ljudsku civilizaciju. Taj sukob, iako je dovodio situaciju do usijanja duže od četiri decenije, ipak se završio mirovnim sporazumom - onim potpisanim na samitu održanom u Parizu od 19. do 21. novembra 1990. godine[1]. Do tada, nikada nije postojala trka u naoružanju poput ove, a ipak to nije dovelo do izbijanja „klasičnog“ rata (Subrahmanyam 2008).

I SSSR i SAD su sve aspekte naučnog rada, nakon pobede u Drugom svetskom ratu, stavile u službu svoje strane u Hladnom rata (vidi Kojevnikov 2004). Proizvodnja atomske bombe je značajno doprinela uočavanju relevantnosti nauke u političkoj borbi. Takav društveni kontekst doveo je do toga da naučne aktivnosti širom sveta počnu drugačije da se posmatraju: u svetlu politike (Krementsov 1997). Percepcija uloge nauke - i u nemarksistčkim sistemima - približila se perspektivi Karla Marksa (Karl Marx), koji ju je posmatrao kao „istorijski dinamičnu i revolucionarnu silu u društvu“ (Marks prema Bernal 1952: 47). U oba bloka nauku su odlikovale sledeće zajedničke karakteristike: gigantomanija, državna podrška, kult nauke u društvu, (kon)fuzija između nauke i inženjerstva, multidisciplinarna istraživanja, kolektivni rad, složena birokratija i militarizacija (vidi Graham 1992 i vidi Kragh 1999). Tehnologije kakve su radar, nuklearna energija, mlazni motor, dalekometne balističke rakete, blizinski osigurač itd. zahtevaju koordiniranu aktivnost naučnika, inženjera, vojske, industrije kao i političku posvećenost stvaranju radnih sistema (Chertok 2010).

Sledstveno tome, neposredno nakon Drugog svetskog rata atomska bomba nalazila se u fokusu spoljene i unutrašnje politike SAD-a. „Atomska bomba je istovremeno simbolizovala i moć nauke i uništenje. I mada su neki naučnici, radeći unutar nacionalne državne bezbednosti, osećali da su sputani, institucionalna moć nauke je cvetala“ (Wolf 2013: 21).[23] Imajući u vidu izuzetan naučni, industrijski i tehnički uspeh na projektu

[1] https://www.osce.org/mc/39516

Menhetn, tamošnji kreatori politike su sumnjali da će bilo koja država uspeti da bude konkurencija „čudesima i užasima“ američke nauke. Američka vojska i političari, 1949. godine suočeni sa činjenicom da i SSSR ima atomsku bombu, ponovo su došli do zaključka da u cilju zaštite treba da se okrenu visokotehnološkom naoružanju, a ne diplomatiji. Nakon što je američki predsednik Truman objavio da SAD tragaju za termonuklearnim oružjem trka u naoružanju između ova dve države zvanično je počela (Wolf 2013). Nijedna evropska država, čak ni Francuska ni Engleska, nisu mogle da se porede sa SAD i SSSR kada je u pitanju uloga vojske u razvoju i primeni fizike (Kragh 1999).

FNRJ U KONTEKSTU HLADNOG RATA I POČECI JUGOSLOVENSKOG NUKLEARNOG PROGRAMA

Istoričar Hobsbaum (2002) posmatra period između 1947. i 1951. godine kao najburniji tokom Hladnog rata. U ovom razdoblju SAD je vodila agresivnu antikomunističku borbu. Sa druge strane SSSR je bio suočen sa pojavom prvih pukotina u svom bloku. Naime, 1948. godine, izbila je međunarodna kriza (Žanin Čalić 2013), tokom koje je Federativna narodna republika Jugoslavija (FNRJ) pod vođstvom Josipa Broza Tita napustila blok predvođen Sovjetskim savezom (Hobsbaum 2002). U Jugoistočnoj Evropi Jugoslavija se isticala kao samostalni centar komunističke moći što nije odgovaralo antikomunistički nastrojenom britanskom premijeru Čerčilu, ali ni komunističkom vođi Sovjetskog saveza Staljinu. Ovo drugo je za rezultat imalo da 28. juna. 1948. godine KPJ bude isključena iz Kominforma pod sumnjom da uvodi kapitalizam (Žanin Čalić 2013). U rezoluciji Informbiroa Jugoslavija se, između ostalog, optužuje i za nacionalističke tendencije[4] (Rezolucija Informacionog biroa komunističkih partija o stanju u Komunističkoj partiji Jugoslavije, 28. juna 1948).

U tom smislu zanimljivo je pomenuti razgovor između našeg istaknutog fizičara Pavla Savića, koji je radio u Institutu za fizičke probleme Sovjetske akademije nauka, čiji je direktor bio poznati naučnik Pjotr Kapica (Пётр Леони́дович Капи́ца), i Josipa Broza Tita, za vreme Titove diplomatske posete SSSR-u u proleće 1946. godine. Prilikom tog susreta Tito je rekao Saviću „Vrati se u zemlju, gradićemo i mi institut“ (Savić, 1978: 306). U jesen iste godine Savić se vratio u Jugoslaviju gde je po partijskoj dužnosti prihvatio da bude prorektor Beogradskog univerziteta. „Kada je došla 1948. godina nije bilo više mogućnosti za vraćanje u Sovjetski savez“ (Savić 1978: 306)[5].

Te 1948. godine uredbom Vlade FNRJ osnovana je Uprava za koordinaciju rada naučnih instituta sa ciljem (koji iz naziva nije lako dokučiv) da pokrene aktivnosti u vezi sa realizacijom najambicioznijeg programa u jugoslovenskoj nauci: razvoj nuklearne tehnologije. Za prvog direktora imenovan je Batrić Jovanović, dotadašnji pomoćnik saveznog ministra za obojenu metalurgiju (Spasić 2013). U oktobru 1952. godine Uprava se seli na novu adresu, a na osnovu nove uredbe menja svoj naziv u Uprava za rudarska istraživanja i rudarske studije. Odlukom Saveznog izvršnog veća (Službeni list FNRJ 18/1953) iz 1953. godine Uprava menja naziv u Zavod za geološko-rudarska i tehnološka istraživanja. Za direktora zavoda imenovan je dpl. hem. Miladin Radulović-Krcun, kasnije direktor Direkcije za nuklearne sirovine pri Saveznoj komisiji za nuklearnu energiju (Spasić 2013). Prolazeći kroz još nekoliko promena imena i formata, konačno januara 1966. godine Institut za tehnologiju nuklearnih i drugih mineralnih sirovina (ITNMS) dobija naziv koji nosi i danas.

1948. godine i Pavle Savić je po odluci Savezne vlade Jugoslavije pristupio izgradnji Instituta za fiziku u Vinči koji je 1950. godine dobio ime „Institut za ispitivanje

[2] Pre rata godišnje ulaganje u nauku od strane (američke) države je iznosilo oko pedeset miliona dolara (novac je pre svega bio namenjen za zdravstvo i poljoprivredu), no do 1950. godine država je za nauku na godišnjem nivou izdvajala više od jedne milijarde dolara (Wolf 2013).

[3] U SAD-u fizika je toliko bila povezana sa vojskom da su neki fizičari bili su strahu da fizika ne postane grana vojske. Filip Morison (Philip Morrison), fizičar angažovan na Menhetn projektu, već 1946. godine izražava zabrinutost zbog militarizacije fizike, ali i razumevanje za kompleksan položaj fizičara (Za više detalja videti Kragh 1999: 297).

[4] Uloga koja se daje državi, kao bitnom elementu marksističko-lenjinističke strategije, makar ona bila i „proleterska“ i nominalno internacionalistički orijentisana, predstavlja važnu metu mnogih kritika koje su sa leva upućene ovoj ideologiji. Segment tih kritika odnosi se i na to da je svaka državna forma, bez obzira na proklamovanu ideologiju, inherentno nacionalistička (Rocker 1997).

[5] Prema Saviću (1978) Kapica je verovao da će SSSR pomoći u poduhvatu pravljenja Instituta u Jugoslaviji. Savić je čak sastavio spisak materijala i aparature koje SSSR treba da da Jugoslaviji, no situacija nije ispalo kako su dvojica fizičara očekivala. Kapica je kasnije po Staljinovoj naredbi poslat u devetogodišnju internaciju (Savić 1978).

strukture materije“, a 1953. godine „Institut Boris Kidrič“[6] (Bondžić 2016). Danas je Institut za nuklearne nauke „Vinča“ institut od nacionalnog značaja za Republiku Srbiju. U izgradnji instituta Saviću je, pored državnih organa, pomagao njegov prijatelj, nuklearni fizičar iz Francuske, Robert Valen, a među prvim saradnicima Savić pominje i profesora Aleksandra Milojevića, koji je donosio materijal i aparaturu za prvu laboratoriju iz Nemačke (Savić 1978). U nabavci prvih instrumenata i opreme za laboratorije pomogao je i profesor Dragoljub Jovanović (Bondžić 2016).

> „Prva mašina za nuklearne reakcije bio je kaskadni akcelerator od milion i po elektronvolti, kupljen kod Erlikena u Švajcarskoj. Prvi kadar regrutovao sam među svojim đacima, kojih je bilo preko hiljadu: fizičara, fizikohemičara, hemičara. Svi su oni slušali atomistiku kod mene na Univerzitetu....Pokrenuli smo Bilten Instituta u Vinči koji sam uređivao....Preko toga Biltena su nas veoma brzo upoznali naučni krugovi izvan naše zemlje, tako da je naša ekipa na prvoj i drugoj međunarodnoj konferenciji za mirnodopsku primenu nuklearne energije u Ženevi nailazila na prijem sa velikim respektom“ [Savić 1978: 307].

Zahvaljujući Savićevom neumornom radu naučna zajednica je prvi put imala naučnu instituciju sa akceleratorima, reaktorima, anlizatorima jona, masenim spektometrima, plazmenim topovima kao i znanje o savremenoj atomistici, biologiji, elektronici, zaštiti od zračenja itd. (Senćanski 1986). „U „maloj“ Vinči, koja je iz dana u dan postajala sve veća, vrilo je kao u košnici, radilo se i danju i noću. Svetla se nisu gasila u biblioteci, u kojoj ni noću nije bilo slobodnih mesta za učenje. Nicale su nove zgrade, gradile se mašine...I nad svim tim poslovima, počev od nabavke hrane pa sve do pronalaženja neophodne, naučne opreme u ratom razorenoj Evropi, bdeo je profesor Savić“ (Senćanski 1986: 58).

Prema Bondžiću (2016), jugoslovenski politički vrh je u tri navrata od naučnika tražio da počnu da se bave razvojem nuklearnog oružja. Istraživanja pokazuju da je Saviću krajem 1950. godine obelodanjeno da partijski vrh insistira na pravljenju atomske bombe (do tada to nigde nije bilo eksplicirano). S obzirom na situaciju u kojoj se Jugoslavija našla posle raskida sa SSSR-om – u strahu od napada od strane SSSR-a (koji 1949. godine i sam dobija atomsku bombu) ali i ostalih država Informbiroa i nesigurna da li će pomoć od strane zapadnih kapitalističkih država uslediti - jasno je zašto je državno rukovodstvo Jugoslavije izlaz iz ove loše vojno-bezbednosne situacije videlo u projektu pravljenja nuklearnog oružja. Istaknuti partijski funkcioner Milovan Đilas tu logiku formuliše na sledeći način: „Ja sam za reč Lenjina: Među vukovima ja urličem. Dok smo okruženi vucima treba se braniti i imati najmoćnija oružja“ (Đilas prema Bondžić 2016: 105).

Pored toga jasno je da bi atomska bomba igrala veliku ulogu za održavanje moći trenutnog državnog rukovodstva Jugoslavije, uz nesumnjiv međunarodni prestiž koji posedovanje atomske bombe donosi. Pavle Savić je suptilno izbegavao otvoreno suprotstavljanje državnim rukovodiocima, nekad i hraneći njihove ambicije u vezi sa atomskom bombom, što je verovatno i dovelo do toga da njegovi stavovi ponekad budu protivrečni, ali sve ukazuje na to da on nikada nije ozbiljno prionuo na zadatak pravljenja oružja, iako je bio svestan da je i sam Institut „Boris Kidrič“ osnovan u te svrhe (Bondžić 2016).

Aleksandar Ranković, Edvard Kardelj i Milovan Đilas su poslali Slobodana Nakićenovića i Stevana Dedijera da kontrolišu Pavla Savića i pomognu (naročito Dedijer) oko pravljenja atomske bombe. Istraživački izvori ukazuju i na razilaženje u pogledima partijskog rukovodstva, koje je želelo bombu, i Savićevog viđenja uloge Instituta (i reaktora), prvenstveno u obuci kadrova, kako bismo u fundamentalnim, nuklearnim naukama bili ravnopravni sa ostatkom razvijenog sveta. Indikacije za ovakav Savićev stav možemo naći i u Izveštaju Uprave za koordinaciju rada naučnih instituta za 1948. godinu gde Savić naglašava „da je Institut u Vinči samo školska ustanova za izgradnju kadra i da se tu ne namerava izgrađivati nikakav krupniji objekat iz oblasti atomske energije izuzevši čisto školske objekte“ (AJ, 836, KMJ-II-6-a/4 prema Bondžić 2016: 106).

Ubrzo je i Dedijer počeo da zastupa shvatanja slična Savićevim. Nakon Staljinove smrti, krajem maja 1953. godine, u ime Instituta nuklearnih nauka Pavle Savić, Stevan Dedijer i Robert Valen sastavljaju *dopis* „O dva bitna uslova za razvitak atomske energije kod nas“ koji dostavljaju „Kabinetu Maršala i drugovima Kardelju,

[6] Institut je ime dobio po državnom i partijskom rukovodiocu Borisu Kidriču, koji je preminuo te iste godine, predsedniku privrednog saveta Jugoslavije koji je imao važnu ulogu i pružao punu podršku pri osnivanju i razvoju Instituta (Bondžić 2016).

Rankoviću i Vukmanoviću“. Na samom početku autori potvrđuju da su aktivnosti u vezi sa atomskom energijom kod nas započete sa ciljem proizvodnje atomskog oružja, kao i za korišćenje u privredne svrhe. U nastavku ukazuju na problem malih količina urana u zemlji, nedovoljnu snagu privrede, kritikuju slabu upućenost političkih i privrednih rukovodioca u pitanja razvoja nuklearne energije, kao i konspirativnost nametnutu stručnjacima, za koju ocenjuju da sprečava dobijanje neophodnih informacija o realnim mogućnostima zemlje.

> „Orijentišemo se na izgradnju jednog reaktora koji treba da bude instrument za naučna i tehnička istraživanja neophodna za razvoj atomske energije uopšte, ukoliko u zemlji postoje uslovi za ovo. Ukoliko ovih uslova nema onda građenje reaktora ne dolazi u obzir i mi se orijentišemo na pripremu minimalnog kadra sposobnog za eksploataciju uređaja za atomsku energiju, ukoliko u budućnosti međunarodna razmena omogući da dođemo do takvih uređaja. U slučaju realizacije reaktora naš Institut bi davao naučnu koncepciju i osnovne tehničke parametre, a naše rudarstvo, industrija i spoljna trgovina imali bi da reše svakako oko 95% svih materijalnih potreba“ [dopis prema Bondžić 2016: 108].

Prvi put se desilo da su se naučnici kritički osvrnuli na nuklearni program i upozorili rukovodstvo na ograničenja tog programa. Takođe, pored toga što su ukazali na štetnost „konspiracije“ naučnici su i zahtevali njeno ublažavanje tvrdeći da čak ni SAD ne skriva organizaciju metoda prospekcije kao ni nalazišta urana. Savić, Valen i Dedijer navode primer za ovo. Jaka konspiracija je bila jedan od razloga koji je sprečavao da se utvrdi koliko procenata urana se nalazi u nekoj rudi i time reši naučni problem koji je trajao tri godine. Na tom problemu se se radilo na više strana, ali zbog konspiracije to su činili ljudi izolovani jedni od drugih. Kada je konačno omogućena razmena iskustava problem je rešen u roku od mesec dana.

> „Na osnovu ovoga predlažemo da se za sada bar za ograničeni broj naučnika iz našeg Instituta, izvrši totalna dekonspiracija o organizaciji, metodama, rezultatima i investicijama na području prospekcije urana, u cilju poboljšanja brzine i kvaliteta ovog rada, koji je condito sine qua non za dalji rad na području atomske energije kod nas“ [*dopis* prema Bondžić 2016: 110]

Kasnije se ovakva praksa ponavljala. Prema Bondžiću (2016) ne postoji direktan odgovor rukovodilaca na *dopis* naučnika, ali može se reći da su dela sledećih godina sasvim dovoljna da bismo uvideli efekat. Nakon što je Đilas pao sa vlasti 1954. godine Stevan Dedijer, je prešao da radi u Institutu „Ruđer Bošković“ u Zagrebu. Robert Valen se vratio u Francusku. Na čelo Instituta, bez naučnih kvalifikacija, postavljen je diplomata i ekonomista Vojko Pavičić. Kardelj, Ranković i Vukmanović su bili zaduženi da oblikuju nuklearnu politiku zemlje, dok je na Institutu u Vinči od autora *dopisa* ostao samo Pavle Savić (Bondžić 2016). Naučnici iz Vinče su se usavršavali na istraživačkom reaktoru u Kjeleru u Norveškoj. Među prvim našim naučnicima sa zapaženijim rezultatima iz oblasti reaktorske fizike treba pomenuti profesora Elektrotehničkog fakulteta u Beogradu Dragoslava Popovića, čije je objavljivanje rada o preseku fisije uranovog izotopa bio senzacija, jer je u pitanju bila do tada nikada javno objavljena informacija važna za proizvodnju nuklearnog oružja (Hymans 2012).

Komisija za pomoć u naučnim istraživanjima održala je sastanak u junu 1954. godine kome su prisustvovali Pavle Savić, Svetozar Vukmanović Tempo, Anton Peterlin, Ivan Supek, Slobodan Nakićenović, Vojko Pavičić, Miladin Radulović, Marko Čančarević, i Milan Osredkar. Na sastanku je vođena i diskusija o izveštajima o radu instituta. Ukratko - navedeno je da je uočen napredak u radu i prvenstveno je stavljen fokus na značaj nuklearne energije i pripreme za njeno korišćenje. Takođe, uočena je i potreba za osamostaljivanjem instituta u budućnosti, kao i potreba za orijentacijom na domaće izvore u ekonomskom smislu. Na sastanku je potvrđeno i da će Komisija finansirati samo radove iz oblasti nuklearnih nauka. Drugim rečima „napori na nuklearnim istraživanjima pod državnim kontrolom i usmerenjem“ su se nastavila. Na sastanku je pomento i kako se Institut u Ljubljani usmerava ka nuklearnim naukama, kao i da Institut u Zagrebu treba da se u većoj meri koncentriše na problematiku iz oblasti nuklearnih nauka. U kasnijem periodu, od 1955. godine, ciljevi su bili usmereni na polje „privredne i mirnodopske primene nuklearne energije“, ali i na prikriveno polje „eventualne proizvodnje atomskog oružja“, „pod strogom kontrolom države i UDB-e“ (Bondžić 2016: 114). Savezno izvršno veće SFRJ formira 1955. godine Saveznu komisiju za nuklearnu energiju (SKNE) kojoj je u zadatak stavljeno

da kao savezni organ „programira, rukovodi i koordinira sve aktivnosti u oblasti nuklearnih nauka i nuklearnih tehnologija kao i u oblasti zaštite od jonizujućeg zračenja“ (Perović-Nešković 2000: 32). Prvi predsednik Komisije bio je državni sekretar za unutrašnju politiku Aleksandar Ranković (Bondžić 2016). Pre osnivanja SKNE država je direktno finansirala institute iz budžetskih sredstava, a sada je to rađeno posredstvom SKNE. Među prvim zadacima SKNE bio je i izbor i priprema za konstruisanje, izgradnju i puštanje u pogon nuklearnog reaktora. Smrću Staljina 1953. godine spor između Jugoslavije i SSSR-a kreće u pravcu razrešenja. 1955. godine Jugoslavija kupuje od SSSR teškovodni reaktor (RA), koji kreće sa radom 1959. godine. Nekoliko meseci pre toga u rad je pušten „nulti“ reaktor (RB), „i tako je ostvarena prva lančana reakcija fisije na Balkanu“ (Ristić 2000: 28). Može se reći da od 1955. godine počinje period procvata nuklearne energije kod nas.

Prema Nakićenoviću (1961) za Jugoslaviju, kao socijalističku zemlju, nauka, tehnologija i obrazovanje bili su veoma visoko pozicionirani na listi prioriteta. Samim tim je i očekivana silina kojom je državna politika usmerila čitavo društvo prema razvoju naučnih i obrazovnih institucija u ratom razorenoj, osiromašenoj, nerazvijenoj državi, do tada prevashodno orijentisanoj na poljoprivrednu proizvodnju. „Osnovna svrha socijalističkog društva ogleda se u nastojanju da se ljudski život učini što bolji i što srećniji“ (Nakićenović 1961: 4). Bez ulaganja u tehnologiju i nauku ovo nije moguće postići, jer nauka i tehnologija predstavljaju sredstva za ostvarenje ovog cilja. Na kraju karajeva ni naučna socijalistička misao ne bi postojala bez „epohalnih naučnih otkrića i progresa u nauci i tehnologiji“ (Nakićenović 1961: 4).

> „Treba uočiti da je Jugoslavija na vreme postala svesna potencijalne uloge i važnosti koja nova postignuća u nauci i tehnologiji mogu igrati u ekonomskom razvoju zemlje. Zato je, ubrzo nakon rata, Jugoslavija inicirala rad u polju nuklearne energije“ [Nakićenović 1961: 9].

ZAKLJUČAK

Ideološke karakteristike sistema, kao noseći uzrok insistiranja na razvoju nuklearne energije, treba posmatrati u kontekstu geopolitičke pozicije Jugoslavije. Ako se prepozna njen položaj u jeku Hladnog rata, nakon raskida sa SSSR-om, jasno je zašto je jugoslovenski državni vrh toliko insistirao na razvoju nuklearnog programa. On je to radio ne samo, kako se u kasnijoj zvaničnoj retorici navodi, u mirnodopske svrhe, već pretežno u vojne svrhe. Imajući u vidu period Hladnog rata, i činjenicu da su dva bloka raspolagala nuklearnim oružjem, i sve vreme radila na njegovom usavršavanju, jasno je da je Jugoslavija u nuklearnom naoružavanju, pored nacionalne bezbednosti, videla i perspektivu nezavisnosti i mogućnost da prema svom nahođenju kroji sopstvenu politiku.

Čini se stoga da sama državna forma, a ne ideologija, u real-političkim odnosima predstavlja uzrok fokusa sistema na određene segmente naučnog rada. U prilog tome govori i činjenica da su i liberalno-demokratski sistemi težili razvoju nuklearnog programa, ulažući svoje resurse prvenstveno u tom smeru, baš kao i Jugoslavija i SSSR.

Ipak, treba imati u vidu da je u osnovi ubrzanih modernizacijskih procesa, koji su nerazdvojni od razvoja nauke i tehnologije, u tadašnjom jugoslovenskom društvu bila neka od varijacija socijalističkih ideologija. Može se stoga zaključiti da, kada je u pitanju Jugoslavija, prvo marksističko-lenjinističku, a zatim samoupravnu socijalističku ideologiju, treba posmatrati kao idejne pretpostavke koje su omogućile postavljanje sistema na strukturne osnove koje su omogućile pokretanje nuklearnog programa.

ZAHVALNICA

Rad je nastao u okviru projekta Teorija i praksa nauke u društvu: multidisciplinarne, obrazovne i međugeneracijske perspektive (registarski broj 179048) koji finansira Ministarstvo prosvete, nauke i tehnološkog razvoja Republike Srbije.

ABSTRACT

Our intention is to present basic outlines of the beginnings of Yugoslav nuclear program. In the paper we examine specifics of the Cold war context, as well as the role and application of science, notably nuclear physics, in that period. The paper is analyzing geopolitical position of FPRY after break with USSR in 1948. and the focus of the Yugoslav political leadership on the development of the nuclear program, while reviewing basic information on the institutes in which this program was developed. In this context dynamics of the relations between representatives of the government and scientists, and importance of those relations for the Yugoslav nuclear program is depicted.

Keywords - FPRY; Cold War; Nuclear Program

Preliminary review of the beginnings of the Yugoslav nuclear program

Uporedna analiza uticaja gama i X zračenja na karakteristike modela gasnog odvodnika prenapona u impulsnom režimu rada

Boris Lončar, Dušan Nikezić, Katarina Karadžić, Luka Rubinjoni i Andrija Janković

***Apstrakt*—Cilj ovog rada je da se ispita eksperimentalno uticaj gama i X zračenja na karakteristike fizičkog modela gasnog odvodnika prenapona za tri materijala elektroda pri tri brzine impulse. Dobijeni rezultati su pokazali da i gama i X zraci dovode do privremenog poboljšanja karakteristika gasnih odvodnika prenapona. Najbolji rezultati se postižu upotrebom elektroda od aluminijuma, pri najbržim impulsima.**

***Ključne reči*—Gasni odvodnik prenapona, histogram, gama zraci, X zraci.**

I. Uvod

Gasni odvodnici prenapona su nelinearni elementi, koji se isključivo koriste za zaštitu od prenapona. Sastoje se od dve ili tri elektrode, koje su zatopljene u keramičko ili stakleno kućište. Oni predstavljaju dvoelektrodnu ili troelektrodnu simetričnu konfiguraciju sa gasnom izolacijom. Kao izolacioni medijum se koristi plemeniti gas (najčešće argon, a može i neon, kripton ili ksenon) ili smeša plemenitih gasova na pritisku od 0,1 kPa do 70 kPa. Troelektrodni gasni odvodnici predstavljaju dva gasna odvodnika u istom balonu, u čijoj unutrašnjosti je plemeniti gas ili smeša plemenitih gasova. Rastojanje između elektroda je reda milimetra ili delova miilimetra [1,2]. Elektrode su tako postavljene da obezbeđuju postojanje pseudohomogenog električnog polja.

II. Pregled dosadašnjih rezultata

Rezultati dosadašnjih ispitivanja pokazuju da su gasni odvodnici prenapona najbolji prenaponski zaštitni elementi u polju radioaktivnog zračenja i stoga se oni mnogo češće koriste u tu svrhu od drugih elemenata za zaštitu od prenapona (prenaponske diode, varistori, kondenzatori) [3,4,5]. Ispitivan je i uticaj gama i X zračenja na karakteristike komercijalnih gasnih odvodnika prenapona [6]. Proučavan je i uticaj materijala elektroda, načina obrade elektrodnih površina, vrste gasa, pritiska i međuelektrodnog rastojanja na pretprobojnu struju komercijalnih odvodnika u polju gama i X zračenja [7,8]. Istraživan je i uticaj materijala elektroda i pritiska na karakteristike modela gasnog odvodnika prenapona u polju gama [9] i X zračenja [10] u jednosmernom režimu rada i uticaj gama i X zračenja na brzinu odziva modela gasnog odvodnika prenapona u impulsnom režimu [11]. Konačno, proučavana je i radijaciona otpornost modela gasnog odvodnika prenapona u polju neutronskog zračenja [12].

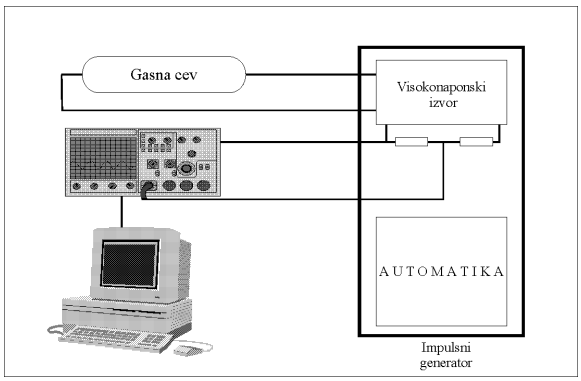
III. Eksperiment

Instrumentacija korišćena u eksperimentalnim ispitivanjima sastojala se od sledećih osnovnih delova:
1) gasno-vakuumska komora; 2) merač pritiska SPEEDIVAC; 3) čelična boca sa argonom pod pritiskom; 4) vakuum pumpa EDWARDS 5; 5) impulsni test generator Haefely tip P6T VF-tel 202671 sa priborom; 6) osciloskop Tektronix TDS 220 SNB036675; 7) izolacioni transformator i 8) koaksijalni kablovi i priključci. Blok šema opreme za eksperimentalna ispitivanja prikazana je na slici 1.

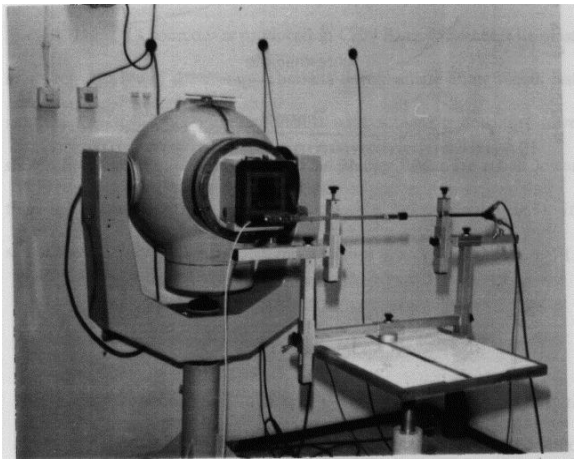


Sl. 1. Blok šema opreme za eksperimentalna ispitivanja

U cilju ispitivanja radijacione otpornosti modela gasnog odvodnika prenapona u radu su korišćeni sledeći izvori zračenja: 1) izvor gama zraka kobalt-60 u polju uređaja IRPIK-B; 2) izvor X zraka u polju dozimetrijskog generatora PHILIPS MG-320.

Izvor gama zraka kobalt-60 nalazi se u uređaju gama polja IRPIK-B koji je prikazan na slici 2 i nalazi se u Metrološko-dozimetrijskoj laboratoriji Instituta za nuklearne nauke Vinča. Ovaj uređaj se sastoji od kontejnera za smeštaj i čuvanje izvora i zračnika. Kontejner je tako postavljen da se uticaj

zračenja iz njega može zanemariti. Debljina zidova zračnika je takva da se intenzitet primarnog zračenja smanjuje hiljadu puta. Oblikovanje snopa se vrši kolimatorom, pri čemu je ugao kolimacije promenljiv. Ovaj uređaj služi za kalibraciju dozimetrijske instrumentacije. Maksimalna dimenzija polja na rastojanju od 1 m je 30 cm x 30 cm. Uzima se da je srednja energija gama fotona E = 1,225 MeV, jer se u spektru izdvajaju dve linije gama fotona, čije su energije 1,331 MeV i 1,173 MeV. Jačina apsorbovane doze gama zračenja u vazduhu iznosila je 96 cGy/h, 960 cGy/h i 1920 cGy/h, respektivno. Jačina ekspozicije iznosila je 7,17 x 10^{-6} C/kgs, 7,17 x 10^{-5} C/kgs i 1,43 x 10^{-4} C/kgs, respektivno.



Sl. 2. Uređaj za realizaciju polja gama zraka IRPIK B

Ispitivanja uticaja X zraka na karakteristike modela gasnog odvodnika prenapona vršena su u polju X zraka dozimetrijskog generatora PHILIPS MG-320, koji je prikazan na slici 3 i koji se nalazi u Metrološko-dozimetrijskoj laboratoriji Instituta za nuklearne nauke Vinča. Istraživanja su vršena u kalibrisanim poljima pri naponima X cevi od 60 kV, 150 kV i 300 kV, respektivno, kojima odgovaraju struje cevi od 15 mA, 10 mA i 10 mA, respektivno. Jačina ekspozicione doze X zraka iznosila je 2,83 x 10^{-6} C/kg s, 5,89 x 10^{-6} C/kg s i 3,46 x 10^{-6} C/kg s.

Sl. 3. Uređaj za realizaciju polja X zraka PHILIPS MG-32

Ispitivanja gasnih odvodnika prenapona vršena su prema sledećoj proceduri: 1) formiranje modela gasnog odvodnika prenapona. Pod tim se podrazumeva izbor odgovarajućeg materijala od koga su napravljene elektrode, smeštanje elektroda u gasno-vakuumsku komoru i podešavanje rastojanja između elektroda; 2) povezivanje formiranog modela (gasne cevi) u gasno - vakuumski sistem, pomoću odgovarajućih ventila, sa vakuumskom pumpom sa jedne strane i dovodom gasa iz čelične boce sa komprimovanim gasom sa druge strane, kao i povezivanje sa meračem pritiska; 3) vakuumiranje sistema, koje podrazumeva uspostavljenje stabilnog pritiska pomoću ventila ka vakuum pumpi i igličastih ventila, koji služe za doziranje pritiska. Pritisak mora biti stabilan, tj. njegova vrednost se ne sme menjati tokom eksperimenta; 4) pozicioniranje gasne komore na određenu jačinu doze; 5) povezivanje modela gasnog odvodnik u električno kolo prema šemi predstavljenoj na slici 1; 6) kondicioniranje elektrodnog sistema, tj. izazivanje serije proboja sa pauzama od 30 s između njih, što omogućava ponovljivost mernih rezultata, odnosno pouzdanost merenja; 7) merenje vrednosti impulsnog probojnog napona i njihovo očitavanje na osciloskopu (po pedeset vrednosti za svaku brzinu impulsa i konkretnu elektrodnu konfiguraciju); 8) promena položaja radne tačke modela gasnog odvodnika i ponavljanje postupka merenja. To podrazumeva promenu parametara gasno-vakuumske komore (materijala elektroda, jačine doze).

Uticaj γ i X zraka na karakteristike modela gasnog odvodnika prenapona ispitivan je za tri materijala elektroda i to: aluminijum, čelik i mesing i pri tri brzine impulsa i to: 1,2/50 μs, 10/700 μs i 100/700 μs.

IV. Rezultati merenja i diskusija rezultata

Dobijeni eksperimentalni rezultati u polju gama zraka za aluminijumske, čelične i mesingane elektrode prikazani su u tabelama 1 – 3, respektivno, a u polju X zraka u tabelama 4 – 6, respektivno.

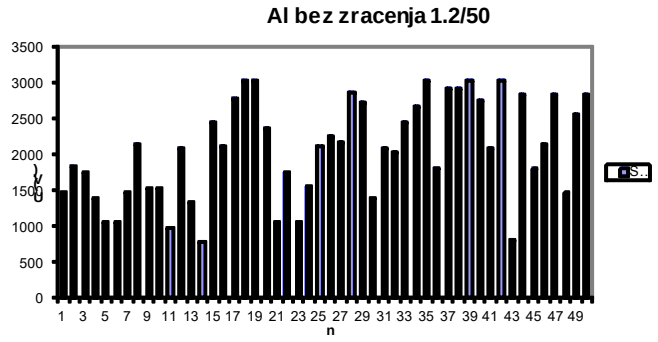
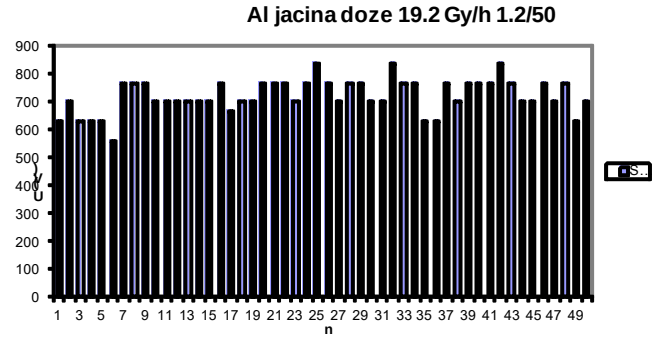
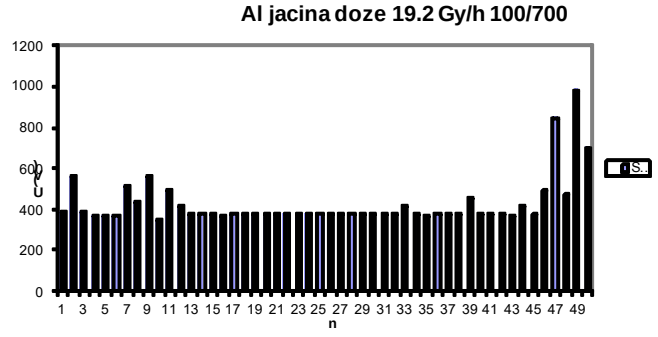
Hronološki nizovi vrednosti probojnog napona za aluminijumske elektrode bez zračenja i pri najvećoj primenjenoj jačini doze gama zračenja od 19,2 Gy/h, pri brzini impulsa 1,2/50 μs, prikazani su na slikama 4 i 5, respektivno, a u slučaju aluminijumskih elektroda pri najvećoj jačini gama doze i najsporijem impulsu 100/700 μs na slici 6.



Sl. 4. Hronološki niz vrednosti probojnog napona za Al elektrode bez zračenja pri impulsu 1,2/50

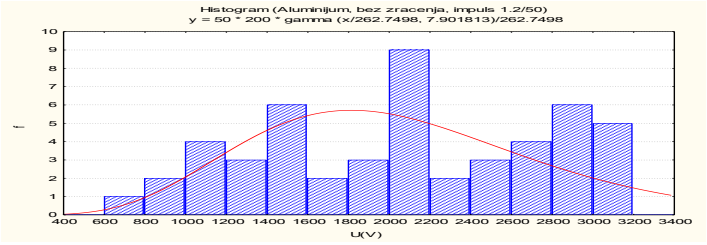


Sl. 5. Hronološki niz vrednosti probojnog napona za Al elektrode pri jačini doze gama zraka od 19,2 Gy/h pri impulsu 1,2/50

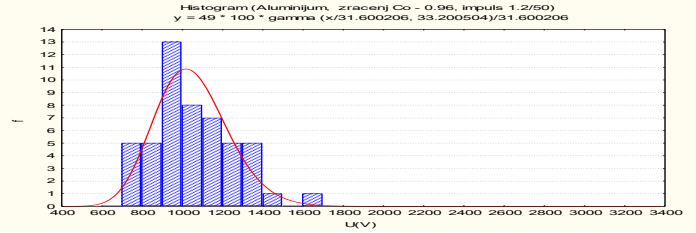


Sl. 6. Hronološki niz vrednosti probojnog napona za Al elektrode pri jačini doze gama zraka od 19, 2 Gy/h pri impulsu 100/700

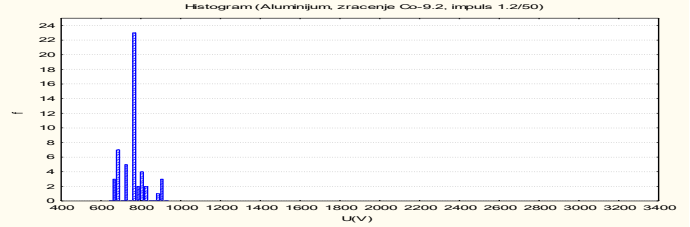
Histogrami vrednosti probojnog napona za aluminijumske elektrode bez zračenja i u polju gama zraka pri jačinama doza od 0,96 Gy/h, 9,6 Gy/h i 19,2 Gy/h, prikazani su na slikama 7 – 10, respektivno. Histogram koji odgovara hronološkom nizu prikazanom na slici 6 dat je na slici 11. Histogram vrednosti probojnog napona u polju gama zraka Co pri jačini doze od 9,6 Gy/h i brzini impulsa 1,2/50 μs u slučaju čeličnih, odnosno mesinganih elektroda prikazani su na slikama 12 i 13, respektivno.



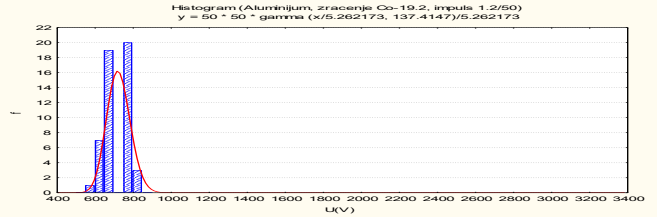
Sl. 7. Histogram vrednosti probojnog napona za Al elektrode bez zračenja pri brzini impulsa 1,2/50



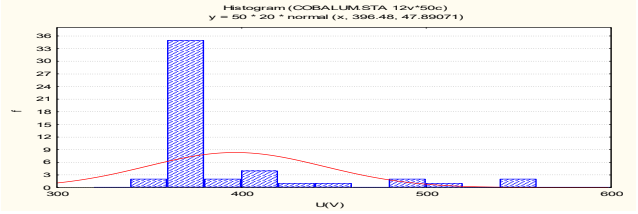
Sl. 8. Histogram vrednosti probojnog napona za Al elektrode u polju gama zraka pri jačini doze 0,96 Gy/h i brzini impulsa 1,2/50



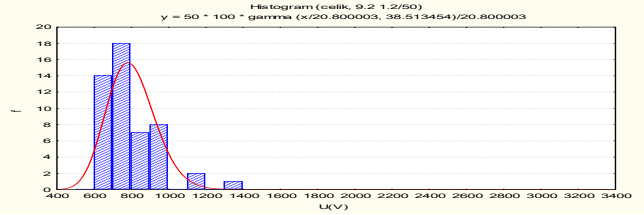
Sl. 9. Histogram vrednosti probojnog napona za Al elektrode u polju gama zraka pri jačini doze 9,6 Gy/h i brzini impulsa 1,2/50



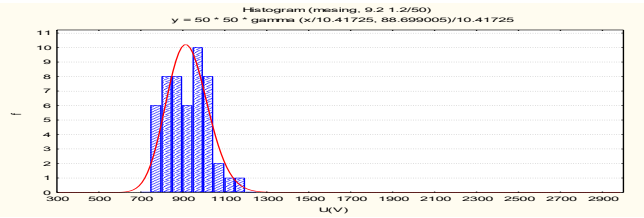
Sl. 10. Histogram vrednosti probojnog napona za Al elektrode u polju gama zraka pri jačini doze 19,2 Gy/h i brzini impulsa 1,2/50



Sl. 11. Histogram vrednosti probojnog napona za Al elektrode u polju gama zraka pri jačini doze 19,2 Gy/h i brzini impulsa 100/700



Sl. 12. Histogram vrednosti probojnog napona za čelične elektrode u polju gama zraka pri jačini doze 9,6 Gy/h i brzini impulsa 1,2/50



Sl. 13. Histogram vrednosti probojnog napona za mesingane elektrode u polju gama zraka pri jačini doze 9,6 Gy/h i brzini impulsa 1,2/50

Na osnovu dobijenih rezultata možemo zaključiti sledeće:

1) Gama zraci dovode do smanjivanja standardnog odstupanja. Dakle, ono dovodi do poboljšanja karakteristika odvodnika. Dobijeni efekti su najviše izraženi kod elektroda od aluminijuma, a najmanje kod čeličnih elektroda.

2) I u slučaju X zraka se najbolji rezultati postižu prilikom upotrebe aluminijumskih, a najlošiji pri upotrebi čeličnih elektroda.

3) Najmanje rasipanje vrednosti probojnog napona je pri najbržim impulsima 1,2/50 μs, a najveće pri najsporijim impulsima 100/700 μs.

Sve navedene promene su reverzibilne i odvodnici nakon prestanka dejstva zračenja ponovo imaju iste karakteristike, kao pre dejstva zračenja (dinamička radijaciona otpornost). Dakle, možemo zaključiti da je u gama polju veoma preporučljiva upotreba modela odvodnika sa elektrodama od aluminijuma i da ovo zračenje dovodi do privremenog poboljšanja karakteristika odvodnika. Pritom se najbolji rezultati postižu pri brzinama impulsa od 1,2/50 μs. I u polju X zraka najbolji rezultati se postižu primenom aluminijumskih elektroda pri impulsima 1,2/50 μs, samo što ono dovodi do neznatnog poboljšanja karakteristika modela gasnog odvodnika prenapona.

V. Zaključak

U ovom radu su prikazani eksperimentalni rezultati ispitivanja karakteristika modela gasnog odvodnika prenapona u polju gama i X zraka u impulsnom režimu rada za tri različita materijala elektroda. Pokazano je da se najveća brzina odziva odvodnika u polja gama i X zraka postiže primenom aluminijumskih elektroda pri najsporijim impulsima.

Abstract

The aim of this paper is to experimentally examine the influence of gamma and X radiation on the gas filled surge arresters physical model characteristics in pulse regime for three materials of electrode and three different pulse. The obtained results showed that gamma and X radiation temporally improved characteristic of gas filled surge arresters. The best results is obtained for aluminium electrode and the fastest pulse.

Comparative analysis of the influence of gamma and X radiation on the gas filled surge arresters model characteristics in pulse regime

Robot Task Extraction and Replication from Raw Video Using Reinforcement Learning

Milivoje Majstorović, Zaviša Gordić, Kosta Jovanović

***Abstract*— This paper presents the underlying concept behind an industrial robot replicating a task demonstrated by a human. The task is extracted from the raw sample video in order to obtain the overall goal. The data is prepared for reward function extraction, after which state-action space is obtained in order to choose most suitable movement. To complete the cycle, the optimal policy for achieving the task is obtained and the task replication is evaluated. The initial tests are performed on a ball throwing motion task without an active gripping element with a set target for the ball – a basketball hoop.**

***Index Terms*—Industrial robotics; Reinforcement learning; Machine learning;**

I. Introduction

Facilitating robot programming and making it more intuitive for the human user is an ongoing and constantly evolving effort towards wider adoption of robotics. With regards to industrial robotics, it is targeted towards enabling faster reprogramming and increased adaptability required by the SMEs and Industry 4.0 in general.

However, analysis and breakdown of a human executed task is a complex and tedious task. Moreover, translating it to an industrial robot movement introduces additional multivariable challenges. For a vast majority of automation problems, the initial goal is to replicate an operator's articulated action, which is easily executed by a human, although complex to break down as a model for robot control. This is where the human demonstration examination and replication comes in handy. Today, some industrial robots already have kinesthetic teaching. In essence, it is a form of supervised learning where it is possible to manipulate the robot by hand, and then store the external path coordinates, which enable the robot to replicate the performed movement. Programming by demonstration [1] is focused on analyzing human actions and action sequences which can be obtained by interacting with a wide range of sensors, while on the other hand monitoring robot execution of the given task is represented as a programming sequence.

The vast majority of industrial robots which are used in an automation production are usually programmed in a static, artificial environment, where the robot has to follow a pre-planned route and to rely on the previous sequence, precise placement, without any deviations and environmental noises. By considering human demonstration footage as input for robot control, object path modeling and robot motion planning are not necessary for the given approach.

In order to demonstrate a concept of an agent observing its environment and adapting after some level of interaction with the environment an exemplary scenario of making a basketball shot was conducted, relying on programming by demonstration. [2]

The second section explains the environment as well as equipment which were used to perform the initial experiments.

The third section explains how the robot tasks are extracted from video material, and two different methods related to the identification of the object of interest.

The architecture of the system needed for reinforcement learning is explained in the fourth section, along with the description of its constituents.

The conclusion is provided in the fifth section, together with some thoughts for future work.

II. Environment Setup

The main component of the system is a 6-axis industrial robot, Denso VP-6242. Additional components are RGB and an RGB-D camera which is used for different aspects of the implementation test. The end-effector mounted on the robot manipulator is a passive 3D printed head cavity which loosely fits the ball in place. A basketball hoop is presented on the right as a target for the algorithm. The environment setup is depicted in figure 1, where the frame of the demonstration video sample was captured.

Figure 1. Demonstration of the task. The task is extracted from the motion performed by a human.

RGB and RGB-D cameras are taken into consideration. Video quality of the RGB camera is 1920 x 1080, 30fps, 16:9 aspect ratio, while the RGB-D camera is a Microsoft Kinect 1, with an RGB resolution of 640 x 480, 30fps and depth resolution of 320 x 240, with a minimum distance of

Milivoje Majstorović is with the School of Electrical Engineering, Signals and Systems Department, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: majstormapp@gmail.com).

Zaviša Gordić is a research associate at the School of Electrical Engineering, Signals and Systems Department, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: zavisa@etf.rs).

Kosta Jovanović is an assistant professor at the School of Electrical Engineering, Signals and Systems Department, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: kostaj@etf.rs).

40cm and a maximum distance of 4.5m. The aforementioned cameras enable two different scenarios.

The first scenario involves using only the RGB camera. The RGB camera enables a 2D setup in which 3 mutually parallel robot axis, are controlled. In this scenario, the hoop position modification is limited by the throwing range of the robot and restricted to the plane orthogonal to the controlled axis of the robot.

The second scenario is based on RGB-D camera, which obtains a 3D point cloud and therefore enables moving the target wherever the robot had theoretical throwing reach. However, in order to achieve that, control of a greater number of robot's axis is needed, increasing the complexity.

For initial implementation tests and proof of concept, it was opted to use only the RGB camera due to its larger resolution and simplicity of the scenario implementation.

Communication with the robot is established by TCP/IP protocol between the robot controller (server side) and a PC running a Linux Virtual Machine (client side). On the client side, a Python script is running which feeds the output data to the robot control in terms of joint positions, velocity and acceleration. Both cameras are directly communicating with the PC where the script is obtaining each frame during the task execution.

III. TASK EXTRACTION

The first phase of an approach to the programming by demonstration task is to translate the demonstration into something meaningful to the machines. This phase is applicable for various tasks, may it be a door opening [3], autonomous driving [4] or pouring a liquid in a cup [5]. In essence, it means that the task should be extracted from all irrelevant background activities and clearly defined. For the particular example, the position of the center of the ball and the hoop on the image is important, since the trajectory of the ball, its distance and/or relative position to the hoop can be used to formulate the task. On the other side, the human arm throwing the ball and all the background is irrelevant.

In order to obtain any reasonable data from raw video footage, it is first needed to extract relevant object information. To this end, two possible approaches were chosen.

The first approach relies on defining an object of interest by analyzing the given environment in order to extract the relevant data.

The second approach uses an off-the-shelf pre-trained model for object detection [6][7] in order to extract the trajectory which the object of interest had.

For the first approach, in order to extract the object of interest, it is first needed to evaluate some of its features and establish thresholds for detecting the object against the rest of the environment. Initially, it was expected to focus on color difference as well as shape difference. Therefore, the emphasis was on defining the HSV range of lower and upper values of the object, thus excluding the complex surrounding and providing a mask for the object of interest. Additional image processing was performed for removing any residual blobs or noise, by using dilation and erosion on the defined mask. After post-processing, it was needed to extract contours from the frame and focus on values related to the largest contour. These values were further used to define a minimum threshold for the contour to be considered, which corresponds to the object of interest. For every frame, x and y values of the detected object in terms of centroid were appended. Appended values from multiple successive frames were interpolated and used for defining a path of interest for replication. The resulting frame is depicted in figure 2, where the interpolated trajectory is colored in red.

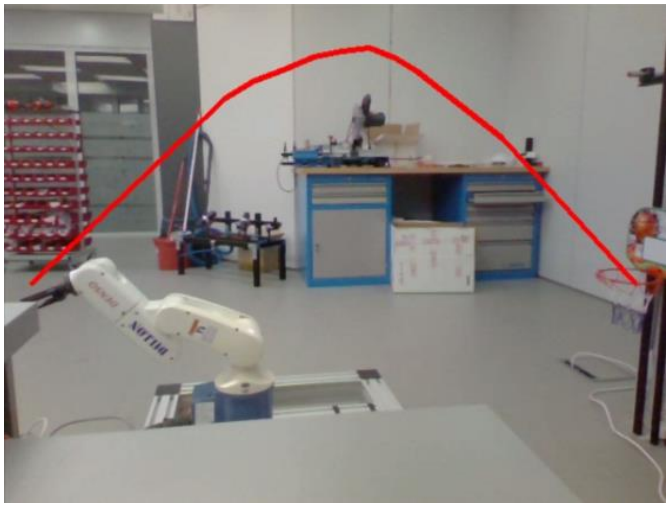

Figure 2. Task extraction by defining a feature to be monitored

The second approach would be to skip the desired object feature definition and rely on a pre-trained model of a sports ball classification. One of those models is YOLO – You Only Look Once. Convolutional Neural Networks are a common starting point in object detection, thus it is reasonable to expect the same to be used in YOLO. It consists of a three-step approach: resizing the image, running the image through a single convolutional neural network and outputting the classification result based on the confidence level threshold of the model. The initial model is trained on the ImageNet 1000-class dataset [8] which also has different kinds of sports balls in its training set. In order to generalize the data and lower the time needed for computation around 80 classes which can be detected were defined and presented with a confidence level. In order to extract the task, the same principle of tracking the ball classified object by centroid was used. The trajectory of the given object was used to form a reward function for providing the agent feedback from real-time object detection. Described method is depicted in figure 3 with corresponding confidence level of detection.

Figure 3. Task extraction by defining a feature to be monitored

Additional information which could be extracted using RGB-D camera is a point cloud, where it is possible to join the localized object in the RGB frame with the same localization of the depth matrix.

Taking everything into consideration, task extraction and reward function engineering are focused on determining object position and where it is relative to the target object. The target object is located based on the backboard square and established prior to the initial training. In future training sets, it will be tracked in real-time in order to adapt to the modifications of the hoop position.

IV. Task Replication

Obtaining the environmental feedback and establishing a robust task extraction sequence is a primary task for feeding the data to a reinforcement learning algorithm. Reinforcement learning presents a type of machine learning method in which the agent receives a reward with delay to evaluate its previous action. Typical reinforcement learning method consists of an Agent which makes a given action which has an impact on the Environment. , in turn, generates an updated Reward value and State upon which the Agent will react with a new Action.

In presented setup Action represents all of the possible movements, in other words, joint values. The state is presented as a current frame captured by the RGB or RGB-D camera. The reward function is constructed based on the difference of the current position of the ball relative to the target trajectory.

Reinforcement learning model can rely on the transition probability where the agent will likely know how to enter a specific state given the current state and action. Opposite to the aforementioned algorithm, model-free algorithm updates parameters based on trial-and-error, as it is the case with Q-learning [8] or deep Q networks (DQN). In order to achieve the continuous control of the Agent and update the robot joint positions, it is needed to refer to an actor-critic model-free algorithm, the algorithm is based on the deep deterministic policy gradient (DDPG) [9], whose architecture is shown in figure 4

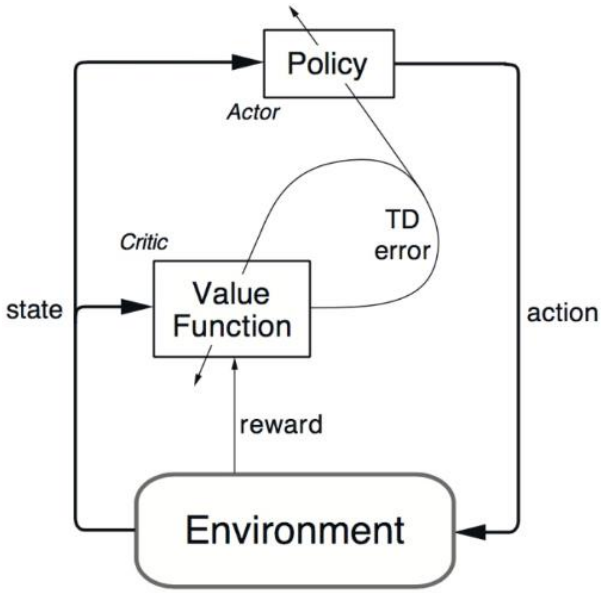

Figure 4. DDPG actor-critic architecture

Initial robot control consists of controlling end positions of 3 robot joints, J2, J3 and J5, which had an impact on the throwing movement. Velocity and acceleration were constant. While learning the policy initial problem was the deceleration of the robot while achieving the specified point. In order to achieve a continuous motion, robot joint actions have to be merged and interpolated in order to minimize the deceleration of the robot when achieving a desired position of the joints. Reward function was constructed to provide additional extreme value for achieving the centroid of the ball in close proximity of few pixels to the center of the basketball board. Figure 5 depicts trajectory obtained from a human demonstration video and it is presented in red, while the robot replication action is shown in blue.

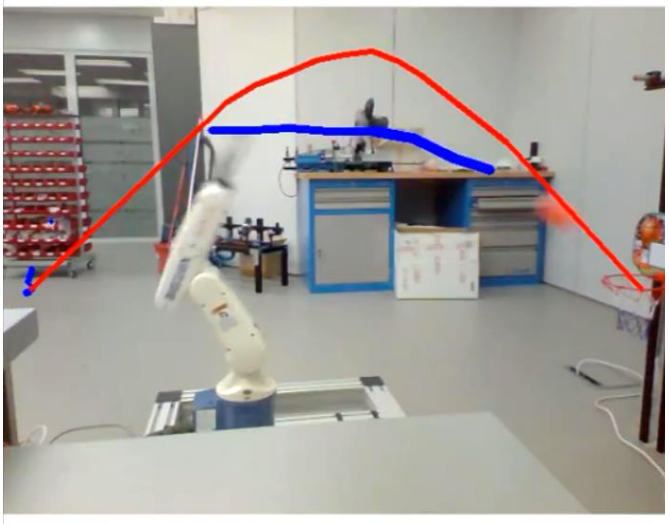

Figure 5. Robot action (blue) and target path (red)

The discrepancy between the given paths was impacted by the fact that the acceleration, deceleration, and velocity were constant. Although an active gripping element can introduce an additional variable and inconsistency, the catapult ejection of the ball is somewhat an unpredictable event. Therefore, it is not possible to maintain the control of the ejection, which was a problem in the region where the

ball had the position update without any connection to the Actor.

With the implementation of the RGB-D camera, we will introduce the control of all 6 joints and train the model on different positions of the hoop in order to establish a sequence-based target movement. While expanding to all joints it is of utmost importance to introduce the velocity, acceleration, and deceleration to the action vector, as the policy couldn't be fully optimized due to the fact that the robot wasn't able to replicate the exact same movement of the human demonstrator.

V. Conclusion

Complex tasks are increasingly being conducted by industrial robots and thus the programming has become more demanding as well as intended to be shorter. Programming by demonstration and imitation learning has been a potential solution for numerous applications. Additional hardware could accelerate the process and achieve better results. Additionally, real-time object detection with a larger class dataset could improve the environmental setup and better map the ball trajectory as well as the target position update. While training and obtaining an action-state space, there are potential problems of achieving an irregular policy although with the achieved goal, for example when gripping a ball model can be trained to exploit the camera angle and appear to be successful without touching the ball.

With the given approach of throwing an object, it is possible to achieve a larger robot reach and not to restrict the work area of the robot. Additional research of grasping different objects could establish a more robust and complete solution as well as more versatile and consistent results.

Further development of the models for programming by demonstration can simplify the overall system implementation of a complex task and provide a more human-like approach and movement for the robot.

Underactuated Finger Design for Flexible Grasping in Robotic Assembly

Lazar Matijašević, *PhD Student*, Petar B. Petrović, *Full Professor*

***Abstract*—At present-day manufacturing and assembly lines, fairly simple mechanism grippers are used. On the other hand, growing demand for customized products that are mass produced, require flexible, multipurpose grippers that are capable of grasping complex objects of different sizes and shapes. In order for robotic hand to be industry acceptable it needs to be robust, easy to control and most importantly it needs to be affordable price-wise. With that in mind concept of multifingered underactuated robotic hand appears as a good candidate to be optimal, general purpose solution. Underactuation as a concept allows robotic hands to grip arbitrary shaped objects without the need for complex control and sensory systems. Also, with less actuators than degrees of freedom multifingered underactuated robotic hand is more affordable and from robot arm carrying capacity standpoint, actuators with less weight allows robotic systems to move faster or to carry heavier loads. For this research linkage driven underactuated mechanisms are chosen because of their rigidity and that trait makes control system more reliable and easier to make thus making whole robotic system more robust and reliable. This paper presents some aspects of design and grasping force analysis of three degrees of freedom (3-DoF) underactuated robotic finger with linkage driven mechanism for CMSysLab Robotic Hand.**

I. Introduction

In industry setting, grasping of various objects in a well-structured or unstructured environment present complex tasks that are still performed by human operators even if environment is dangerous. The new production paradigm of mass customization and extensive needs for application of robotic technology in domain of Small and Medium Enterprises (SME), imposes demands for highly flexible, multipurpose gripers that are capable of precise and reliable grasping complex objects of different sizes and shapes, including in hand manipulation. In order to accommodate demands of mass customization and market push for ubiquitous use of robotic technology in SME operations, both robotic arms and robotic hands that approach performances of humans in terms of dexterity and adaptation capabilities must be developed, [1].

Robotic hands that can, to some degree, mimic human hand capabilities are using principle of complete actuation. One example of fully-actuated robotic hand is Shadow Dexterous Hand [2]. These fully-actuated robotic hands have some disadvantages like: space needed to put all actuators in, increased weight of such hand, complexity of control system needed to operate properly and biggest one, from application point of view, is high price of these hands.

On the other hand, prototypes are made that involve a smaller number of actuators than degrees of freedom. This approach, called underactuation is implemented through the use of passive elements like mechanical limits and springs leading to a mechanical adaptation of the finger to the shape of the object to be grasped.

In case of robotic grasping, underactuation allows the robotic hand to adjust itself to a wide range of shapes, including irregularly shaped objects, without the need for complex control strategies, sensory systems for feedback and replaceable mechanical parts. These underactuated robotic hand systems don't need complex control systems to operate, also have smaller mass and on top of that they are less expensive than fully actuated robotic hands and can even compare to regular grippers when it comes to price. These traits makes them a good choice when considering development of more flexible griping systems to use in industry.

Underactuation in robotic hands leads to some intriguing properties. Underactuated robotic hands cannot always ensure full whole-hand grasping. Distribution of the forces onto the different phalanges is predetermined by the mechanical design of the hand and in some configurations phalanges may not be able to actually exert any force. This uncontrollable force distribution can also lead to unstable grasps: a continuous closing motion of the actuator tending to eject the object [3] as shown on Fig.1.

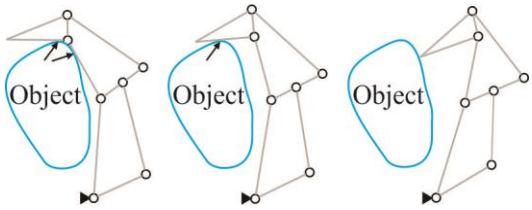

Fig. 1. Unstable grasp of object.

Designing and building underactuated robotic finger that can adapt to any object but can never actually grasp it is futile and to avoid that it is important to do a force analysis of that robotic finger.

In this paper, a new design of the robotic hand, i.e., the CMSysLab Hand, will be presented, focusing to its building block, an uderactuated finger, and within this scope it will be shown how to calculate force that each phalange exerts on object grasped. That information is important in understanding and prevention of above mentioned phenomenon of grasp degeneration and ejection of object.

II. General Analytical Model

In this chapter, a method for obtaining information about force capabilities of robotic n-DoF fingers will be presented. This method is based on approach presented in [4] and [5]. This method will allow one to completely describe the relationship between the input torque of the finger actuator and the contact forces distribution on the phalanges.

For purpose of describing the proposed method, object of grasping will be considered fixed in space and friction will be ignored. Fixing object in space make proposed model predictable and allow for only one finger to be evaluated without the influence of another finger or moving object.

The neglecting friction by itself is very restrictive, but this assumption makes mathematical model relaxed and allows for primary aim of this paper which is to study the capability of the finger, and only finger, to exert contact force on the fixed object. In this stage of our research, our goal is to determine how is actuating torque transmitted through the kinematical chain of the finger and to determine its impact and impact of passive springs on contact force that is exerted on object. Obviously, above mentioned friction properties of contact between object and finger, as well as friction in joints of the finger have tremendous impact on grasping stability, and it will be part of second stage of our research. Friction properties of system are highly unpredictable and including those in this stage of research brings high level of uncertainty to the mathematical model. The significance of such model is questionable without proper experimental results and therefore it will be done with experimental setup that is in finishing stages of design.

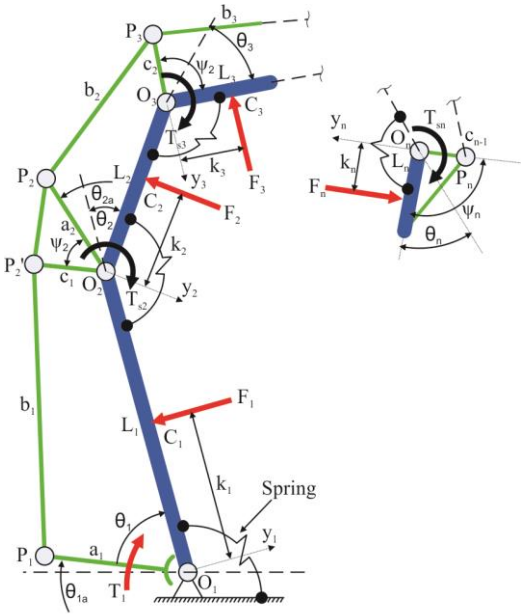

Fig. 2. Representation of n-DoF finger.

An underactuated robotic finger with *n* phalanges is illustrated in Fig. 2. The input torque from actuator is applied to the first joint of the finger, and it is transmitted to the phalanges through four-bar linkages (FBL).

Adding the springs to the joints results with fully adaptive finger with compliant joints. Passive elements are used to cinematically constrain the finger, and to ensure that finger will adapt to the shape of object being grasped.

The following parameters are presented on Fig. 2:

- L_i - the length of the i^{th} phalanx,
- a_i - the length of the first driving bar of the i^{th} FBL,
- b_i - the length of the i^{th} underactuated bar,
- c_i - the length of the second driving bar of the i^{th} FBL,
- θ_i - the rotating angle of the i^{th} phalanx,
- ψ_i - the angle between O_iP_i' and O_iP_i,
- T_1 - the torque of the actuator at the first joint,
- T_{si} - the spring torque of the i^{th} joint,
- F_i - the contact force of the i^{th} phalanx,
- k_i - position of contact point on the i^{th} phalanx.

In order to determine the distributions of the contact forces that depend on the contact point location and the joint torques inserted by springs, it is necessary to perform a quasi-static modeling of the finger. Equating the input and the output virtual powers of the finger, it yields:

$$T^T \omega_a = F^T v \tag{1}$$

where T represents the input torque vector from the actuator and springs, ω_a is the corresponding velocity vector, F is the contact force vector, and v is the projected velocity vector of the contact points:

$$T = \begin{bmatrix} T_1 \\ T_{s2} = -K_2\Delta\theta_2 \\ T_{s3} = -K_3\Delta\theta_3 \\ \dots \\ T_{sn} = -K_n\Delta\theta_n \end{bmatrix},\ \omega_n = \begin{bmatrix} \dot\theta_{1a} \\ \dot\theta_{2a} \\ \dot\theta_{3a} \\ \dots \\ \dot\theta_n \end{bmatrix},\ F = \begin{bmatrix} F_1 \\ F_2 \\ F_3 \\ \dots \\ F_n \end{bmatrix},\ v = \begin{bmatrix} v_{yc1} \\ v_{yc2} \\ v_{yc3} \\ \dots \\ v_{ycn} \end{bmatrix}, \tag{2}$$

where K_i is the stiffness of the torsional spring in joint O_i, and $\Delta\theta$ is the displacement between the current and initial angles of the joint O_i

Projected velocities can be expressed as a product of a Jacobian matrix J_T and the derivative vector of the phalanx joint coordinates, $\theta = [\theta_1, \theta_2, \theta_3, \dots, \theta_n]^T$:

$$v = J_T\dot\theta. \tag{3}$$

The Jacobian matrix J_T, of the projected velocities, can be obtained in a lower triangular form:

$$J_T = \begin{bmatrix} k_1 & 0 & 0 & \dots & 0 \\ \alpha_{12} & k_2 & 0 & \dots & 0 \\ \alpha_{13} & \alpha_{23} & k_3 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ \alpha_{1n} & \alpha_{2n} & \alpha_{3n} & \dots & k_n \end{bmatrix};\ \alpha_{ii} = k_i. \tag{4}$$

Matrix member α_{ij} can be calculated:

$$\alpha_{ij} = k_j + \sum_{k=i}^{j-1} L_k \cos\left(\sum_{m=k+1}^{j} \theta_m\right);\ i < j. \tag{5}$$

By using differential calculus, it is possible to relate the vector to the derivatives of the phalanx joint coordinates defined previously with an actuation Jacobian matrix J_a:

$$\dot\theta = J_a\,\omega_a. \tag{6}$$

In case of underactuated finger model, the four-bar linkage mechanism is used to transmit the actuator torque to each phalanx.

Principle of transmission provides the angular velocity ratio of four-bar linkage that is known as Kennedy's Theorem [6], which states that the three instantaneous centers of rotation shared by three rigid bodies in relative planar motion to another (whether or not connected) all lie on the same straight line.

Considering i^{th} four-bar linkage $O_iP_iP'_{i+1}O_{i+1}$:

$$\dot{\theta}_i = \dot{\theta}_{ia} + \dot{\theta}_{i+1a}\frac{c_i\left(L_i\sin\left(\theta_{i+1a}-\psi_{i+1}\right)-a_i\sin\left(\theta_i-\theta_{ia}+\theta_{i+1a}-\psi_{i+1}\right)\right)}{a_i\left(L_i\sin\left(\theta_i-\theta_{ia}\right)+c_i\sin\left(\theta_i-\theta_{ia}+\theta_{i+1a}-\psi_{i+1}\right)\right)}.$$

Considering last four-bar linkage $O_{n-1}P_{n-1}P_nO'_n$:

$$\dot{\theta}_{n-1} = \dot{\theta}_{n-1a} + \dot{\theta}_n\frac{c_{n-1}\left(L_{n-1}\sin\left(\theta_n-\psi_n\right)-a_{n-1}\sin\left(\theta_{n-1}-\theta_{n-1a}+\theta_n-\psi_n\right)\right)}{a_{n-1}\left(L_{n-1}\sin\left(\theta_{n-1}-\theta_{n-1a}\right)+c_{n-1}\sin\left(\theta_{n-1}-\theta_{n-1a}+\theta_n-\psi_n\right)\right)}.$$

Equation (7) is obtained by substituting equations for $\dot{\theta}_i$ and $\dot{\theta}_{n-1}$ into (6).

$$\begin{bmatrix}\dot{\theta}_1\\ \dot{\theta}_2\\ \dot{\theta}_3\\ \cdots\\ \dot{\theta}_n\end{bmatrix} = \begin{bmatrix}1 & X_1 & 0 & \cdots & 0\\ 0 & 1 & X_2 & \cdots & 0\\ \cdots & \cdots & \cdots & \cdots & \cdots\\ 0 & 0 & 0 & \cdots & X_{n-1}\\ 0 & 0 & 0 & \cdots & 1\end{bmatrix}\begin{bmatrix}\dot{\theta}_{1a}\\ \dot{\theta}_{2a}\\ \dot{\theta}_{3a}\\ \cdots\\ \dot{\theta}_{na}\end{bmatrix}, \quad (7)$$

where

$$X_i = \frac{c_i\left(L_i\sin\left(\theta_{i+1a}-\psi_{i+1}\right)-a_i\sin\left(\theta_i-\theta_{ia}+\theta_{i+1a}-\psi_{i+1}\right)\right)}{a_i\left(L_i\sin\left(\theta_i-\theta_{ia}\right)+c_i\sin\left(\theta_i-\theta_{ia}+\theta_{i+1a}-\psi_{i+1}\right)\right)}, \quad (8)$$

$$X_{n-1} = \frac{c_{n-1}\left(L_{n-1}\sin\left(\theta_n-\psi_n\right)-a_{n-1}\sin\left(\theta_{n-1}-\theta_{n-1a}+\theta_n-\psi_n\right)\right)}{a_{n-1}\left(L_{n-1}\sin\left(\theta_{n-1}-\theta_{n-1a}\right)+c_{n-1}\sin\left(\theta_{n-1}-\theta_{n-1a}+\theta_n-\psi_n\right)\right)}. \quad (9)$$

Function X_i is function that describes the transmition of actuator torque to the i^{th} phalanx.

Equation (10) that provides a practical relationship between the actuator torques and contact forces is derived from (1), (3) and (6):

$$F = J_T^{-T}J_a^{-T}T \quad (10)$$

This equation is only valid in case when $k_1k_2k_3\ldots k_n \neq 0$, which is the condition of singularity for matrix J_T. Matrix J_a cannot be singular, but, the finger may perform contact with the object in case that number of phalanges in contact with object is fewer than n. This assumption results in a singularity of the matrix J_T, so that (10) is not applicable.

III. KINETOSTATIC FORCE DISTRIBUTION MODEL

In order for a less-than-n phalanx grasp to be stable, every phalanx in contact with the object should have a strictly positive corresponding force. In grasping process, the contact appear not only with all phalanges, but also with fewer than n phalanges.

The corresponding generated forces for phalanges which are not in contact with the object should be zero, because that forces can also be seen as the external forces needed to counter the actuation torque. However, calculation of contact forces in case of fewer-than-n phalanges touching by object by using Equation (10) can be a problem because of the singularity of the matrix J_T.

This problem can be solved by proposing a general method to determine the distributions of contact forces in all cases of gripper behaviors in object grasping. In order to do that, it is assumed that the stability of the grasp must be satisfied in all cases.

From Equations (10) it is obtained:

$$J_T^TF = J_a^{-T}T, \quad (11)$$

where the component $J_a^{-T}T$ on the right side is the torque vector $\tau = [\tau_1, \tau_2, \ldots, \tau_n]^T$ at all joints of the finger relating to the actuator, spring torques and functions of torque transmission between actuator and phalanges, which is described by following equation:

$$\begin{bmatrix}\tau_1\\ \tau_2\\ \tau_3\\ \cdots\\ \tau_n\end{bmatrix} = J_a^{-T}T = \begin{bmatrix}1 & X_1 & 0 & \cdots & 0\\ 0 & 1 & X_2 & \cdots & 0\\ \cdots & \cdots & \cdots & \cdots & \cdots\\ 0 & 0 & 0 & \cdots & X_{n-1}\\ 0 & 0 & 0 & \cdots & 1\end{bmatrix}^{-T}\begin{bmatrix}T_1\\ T_{s2}\\ T_{s3}\\ \cdots\\ T_{sn}\end{bmatrix} \quad (12a)$$

which leads to:

$$\begin{bmatrix}\tau_1\\ \tau_2\\ \tau_3\\ \cdots\\ \tau_n\end{bmatrix} = \begin{bmatrix}T_1\\ T_{s2}-X_1T_1\\ T_{s3}-X_2T_{s2}+X_1X_2T_1\\ \cdots\\ T_{sn}+\sum_{j=1}^{n-1}\left[(-1)^{n-j}\prod_{i=j}^{n-1}X_iT_{si}\right]\end{bmatrix}, T_{s1}\equiv T_1. \quad (12)$$

The left part of (11) can be expressed as:

$$J_T^TF = \begin{bmatrix}k_1 & 0 & 0 & \cdots & 0\\ \alpha_{12} & k_2 & 0 & \cdots & 0\\ \alpha_{13} & \alpha_{23} & k_3 & \cdots & 0\\ \cdots & \cdots & \cdots & \cdots & \cdots\\ \alpha_{1n} & \alpha_{2n} & \alpha_{3n} & \cdots & k_n\end{bmatrix}^T\begin{bmatrix}F_1\\ F_2\\ F_3\\ \cdots\\ F_n\end{bmatrix}. \quad (13)$$

By substituting Equations (12) and (13) in (11), it follows:

$$\begin{bmatrix}\tau_1\\ \tau_2\\ \tau_3\\ \cdots\\ \tau_n\end{bmatrix} = \begin{bmatrix}k_1 & 0 & 0 & \cdots & 0\\ \alpha_{12} & k_2 & 0 & \cdots & 0\\ \alpha_{13} & \alpha_{23} & k_3 & \cdots & 0\\ \cdots & \cdots & \cdots & \cdots & \cdots\\ \alpha_{1n} & \alpha_{2n} & \alpha_{3n} & \cdots & k_n\end{bmatrix}^T\begin{bmatrix}F_1\\ F_2\\ F_3\\ \cdots\\ F_n\end{bmatrix}. \quad (14)$$

This equation shows that the torque τ_i at the i^{th} joint of the finger is calculated with respect to the contact forces vector F and parameters α_{ij}, as shown in following equation:

$$\sum_{j=i}^{n}\alpha_{ij}F_j = \tau_i, \quad \alpha_{ii} = k_i. \quad (15)$$

In case when number of phalanges in contact with object is fewer than n (e.g., when the i^{th} phalanx is not touching the object), the parameters α_{ij} in (15) are not relevant and F_i is zero. This means that (15) does not meet this condition, so it is not considered when computing the torque τ_i in case when the i^{th} phalanx is not touching the object. In order to calculate the contact forces vector F in (14), except for F_i, the following process must be used:

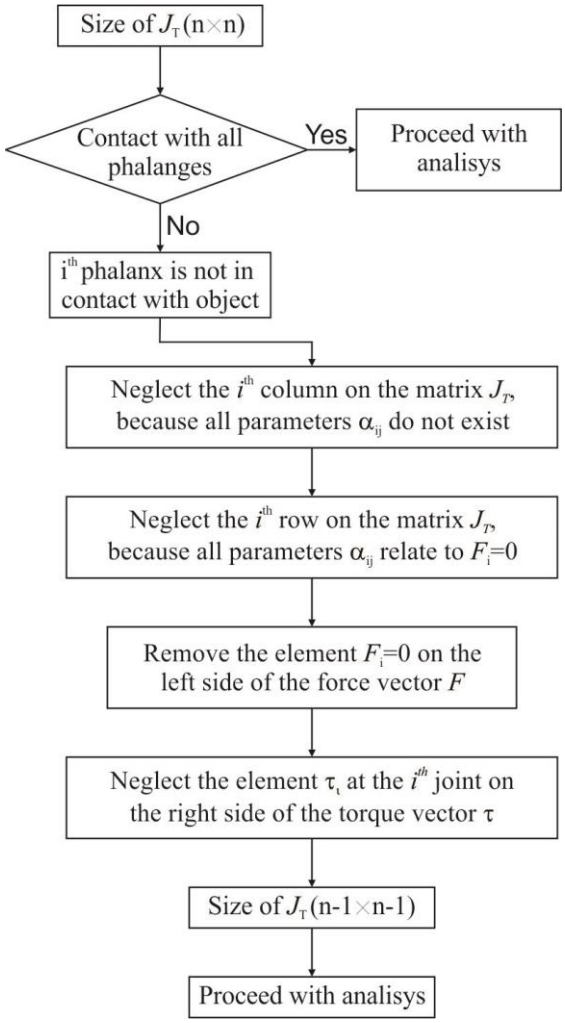

Fig. 3. Algorithm for calculating force parameters in case when not all phalanges are in contact with object.

After neglecting the i^{th} column and i^{th} row, dimension of the matrix J_T is reduced by $n-1\times n-1$, while it is guaranteed that matrix J_T will not be singular. Consequently, Equation (14) can be used in order to calculate the contact forces, except for force F_i on the i^{th} phalanx. The same process is also used in case when more than one phalanx is not in contact with the object.

IV. CMSysLab Hand finger design

Aim of this research is to develop multifingered underactuated hand for use in industry setting for tasks of extremely diversified robotic assembly and enable ubiquitous use in industry, in particular SME compatibility. For this purpose we have entered in development of the underactuated robotic finger that uses sets of linkages to transmit torque from actuator to phalanges. CMSysLab Hand finger is designed in such a manner that it allows easy installation of various sensors and building various configurations of the multifingered hands, including reconfigurable hands, making it optimal building block for various research purposes. Underactuated robotic finger design for CMSysLab Hand has three phalanges and therefore 3-DoF.

Parameters of finger for CMSysLab robotic hand are based on actual proportions of finger of human hand. The set of parameters presented in Table 1 is taking into account the mechanical joint limits, which are key elements in the design of underactuated fingers, when considering stability issues, because they limit the shape adaptation to reasonable configurations.

TABLE I
PARAMETERS OF CMSYSLAB UNDERACTUATED FINGER

a_1 [mm]	30	a_2 [mm]	23
b_1 [mm]	60.5	b_2 [mm]	37
c_1 [mm]	15	c_2 [mm]	14
L_1 [mm]	64.5	ψ_2 [°]	52
L_2 [mm]	37.5	ψ_3 [°]	90
L_3 [mm]	34.5		

Geometric and contact force parameters of underactuated 3-DoF finger are described in Fig. 4.

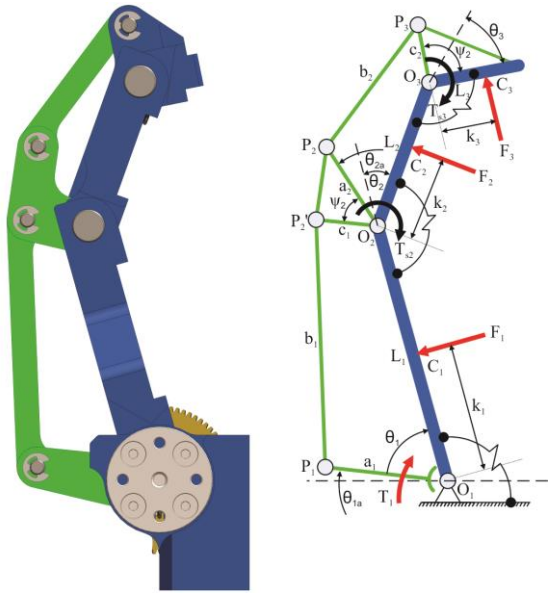

Fig. 4. Geometric and force parameters of underactuated 3-DoF finger.

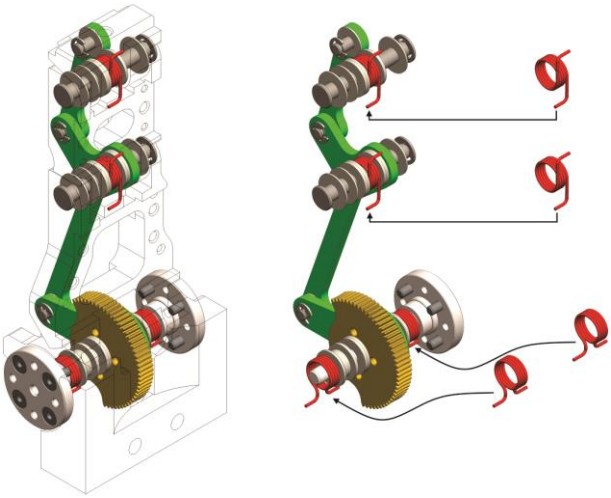

Fig. 5. Mechanical structure of underactuated 3-DoF finger.

The behavior of the finger is mostly determined by its geometry. Depending on the geometric parameters of the

mechanism, it is possible to obtain the final stability of the grasp. In structure of the finger, shown on Fig. 5, mechanical limit is used, which allows a pre-loading of the spring , shown with red color, to prevent any undesirable motion of the medial and distal phalanges, due to its own weight and/or inertial effects, as well to prevent hyperflexion of the finger. In Fig. 6 workspace as well as pre-forming stages of such finger are shown.

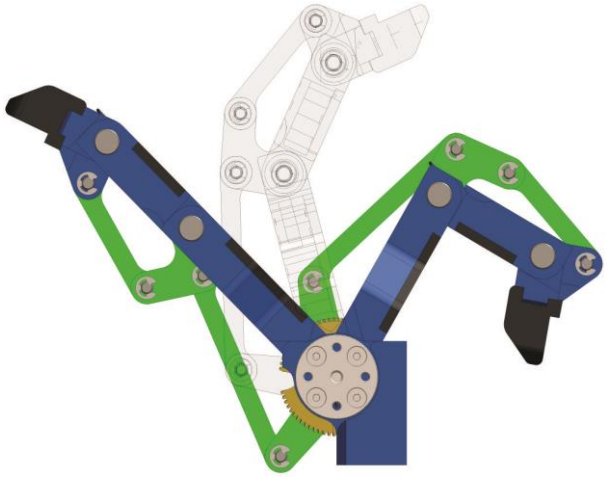

Fig. 6. Workspace of underactuated 3-DoF finger.

V. CONTACT FORCE ANALYSIS

In case of the underactuated finger with 3-DoF, (10) holds if and only if $k_1 k_2 k_3 \neq 0$, which represents the condition of singularity for the matrix J_T, as shown in Fig. 5. There are however other cases, where finger can contact the object when one or two phalanges of the finger are not touching the object, which is shown in Fig. 7, 8,9 and 10.

In order to calculate the contact forces F_1, F_2 and F_3 on the grasping object, it is necessary to separate four cases of possible behaviors between the finger and the object during grasping process.

Case 1: All three phalanges of the finger are in contact with the object, so $k_1 k_2 k_3 \neq 0$, as shown in Fig. 7.

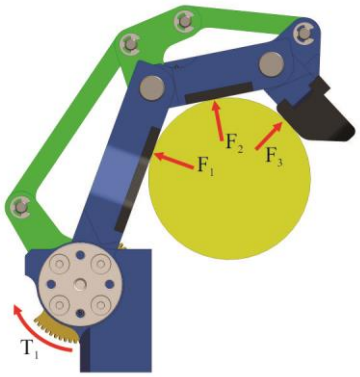

Fig. 7. Representation of 3-DoF robotic finger in case were all phalanges are in contact with grasped object.

The relationship between the actuator torques and contact forces can be derived from (14):

$$\begin{bmatrix} k_1 & k_2 + L_1C_2 & k_3 + L_1C_{23} + L_2C_3 \\ 0 & k_2 & k_3 + L_2C_3 \\ 0 & 0 & k_3 \end{bmatrix} \begin{bmatrix} F_1 \\ F_2 \\ F_3 \end{bmatrix} = \begin{bmatrix} T_1 \\ T_{s2} - X_1T_1 \\ T_{s3} - X_2T_{s2} + X_1X_2T_1 \end{bmatrix}. \quad (16)$$

From previous equation, the three contact forces F_1, F_2 and F_3 can be computed by using Equations (17), (18) and (19), respectively:

$$F_1 = \frac{T_1}{k_1} - \frac{(k_2 + L_1C_2)(T_{s2} - X_1T_1)}{k_1k_2} - \frac{(k_3 + L_1C_{23} + L_2C_3)(T_{s3} - X_2T_{s2} + X_1X_2T_1)}{k_1k_3} + \frac{(k_2 + L_1C_2)(k_3 + L_2C_3)(T_{s3} - X_2T_{s2} + X_1X_2T_1)}{k_1k_2k_3} \quad (17)$$

$$F_2 = \frac{T_{s2} - X_1T_1}{k_2} - \frac{(k_3 + L_2C_3)(T_{s3} - X_2T_{s2} + X_1X_2T_1)}{k_2k_3} \quad (18)$$

$$F_3 = \frac{T_{s3} - X_2T_{s2} + X_1X_2T_1}{k_3} \quad (19)$$

Case 2: The proximal and distal phalanges are in contact with the object, which means that parameter k_2 does not exist, while force F_2 is zero, as illustrated in Fig. 8.

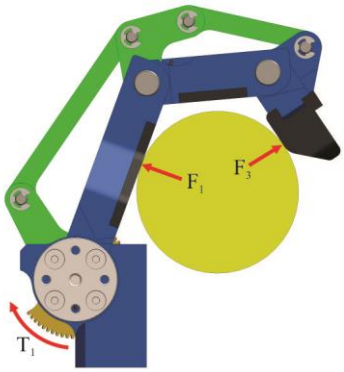

Fig. 8. Representation of 3-DoF robotic finger in case were proximal and distal phalanges are in contact with grasped object.

In Equation (16), the second column and second row in the matrix J_T relating to the medial phalanx are removed, as well as the force F_2 and the torque $\tau_2 = T_{s2} - X_1T_1$ in the vectors F and τ. After removal of aforementioned elements, (16) obtains the following form:

$$\begin{bmatrix} k_1 & k_3 + L_1C_{23} + L_2C_3 \\ 0 & k_3 \end{bmatrix} \begin{bmatrix} F_1 \\ F_3 \end{bmatrix} = \begin{bmatrix} T_1 \\ T_{s3} - X_2T_{s2} + X_1X_2T_1 \end{bmatrix}, \quad (20)$$

where forces F_1 and F_3 are calculated using (21) and (19), respectively:

$$F_1 = \frac{T_1}{k_1} - \frac{(k_3 + L_1C_{23} + L_2C_3)(T_{s3} - X_2T_{s2} + X_1X_2T_1)}{k_1k_3}. \quad (21)$$

Case 3: The medial and distal phalanges are in contact with the object, which means that parameter k_1 does not exist, while force F_1 is zero, as illustrated in Fig. 9.

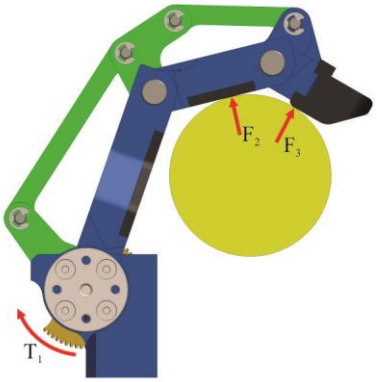

Fig. 9. Representation of 3-DoF robotic finger in case were medial and distal phalanges are in contact with grasped object.

In Equation (16), the first column and first row in the matrix J_T relating to the proximal phalanx are removed. Also, the elements F_1 and τ_1 in the force vector F and torque vector τ are removed. Then (16) becomes:

$$\begin{bmatrix} k_2 & k_3 + L_2C_3 \\ 0 & k_3 \end{bmatrix} \begin{bmatrix} F_2 \\ F_3 \end{bmatrix} = \begin{bmatrix} T_{s2} - X_1T_1 \\ T_{s3} - X_2T_{s2} + X_1X_2T_1 \end{bmatrix}, \quad (22)$$

where F_2 and F_3 are calculated by using (18) and (19), respectively.

Case 4: Only the distal phalanx is in contact with the object, which means that parameters k_1 and k_2 do not exist, while elements F_1 and F_2 of force vector F are zero, as illustrated in Fig. 10.

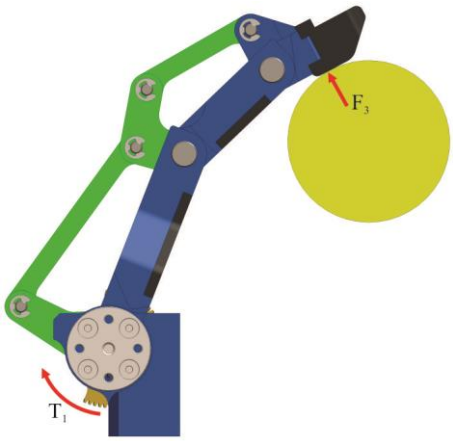

Fig. 10. Representation of 3-DoF robotic finger in case were only distal phalanx is in contact with grasped object.

In Equation (16), the first and second column and row in the matrix J_T relating to the proximal and medial phalanges are removed, as well as the elements F_1 and F_2 of the force vector F, and element τ_2 of the torque vector τ. Then, Equation (16) becomes:

$$k_3F_3 = T_{s3} - X_2T_{s2} + X_1X_2T_1, \quad (23)$$

where F_3 is calculated by using Equation (19).

VI. Conclusion

In this paper, a method for obtaining information of the force acting upon phalanges was presented. This kind of force analysis is important so that researchers and designers of underactuated robotic hands can design proper underactuated finger that has stable grasp of object. These hands have to be robust enough and to have stable grasp if they were to be used in industry setting.

As part of future research this proposed mathematical model for analysis of force distribution on phalanges is going to be supplemented with actual experimental results from experiments with first two finger underactuated CMSysLab Hand.

Future work on CMSysLab Hand will also include simulation of this hand in various softwares and authentication of results through experiments. Design of CMSysLab Hand allows the hand to be equipped with different sensory systems so that experiments can be done.

Future research also must include optimization of four-bar linkages and calculation and optimization of springs that are used to counter inertial effects due to phalanges own weight and friction.

End-Effector Cartesian Stiffness Optimization: Sequential Quadratic Programming Approach

Nikola Knežević, Branko Lukić, Kosta Jovanović, Tadej Petrič and Leon Žlajpah

***Abstract*—Control of end-effector stiffness (or the whole mechanical impedance) is still a critical open issue in physical human-robot interaction. This paper presents an optimization approach for shaping the Cartesian stiffness of a robot end-effector. This research targets collaborative robots with intrinsic compliance - serial elastic actuators. Although robots with serial elastic actuators have constant joint stiffness, kinematic redundancy for a specific task (null-space) could be used for robot reconfiguration and shaping Cartesian stiffness matrix while still keeping the end-effector Cartesian position unchanged. The method proposed in this paper is Sequential Least SQuares Programming (SLSQP) algorithm, which presents an expansion of the quadratic programming algorithm for nonlinear functions with constraints. The method is tested in simulations for 4 DOF planar robot. Results are presented for control of the end-effector Cartesian stiffness initially along one axis, and then control of stiffness along both axis planarly - shaping the main diagonal of the end-effector Cartesian stiffness matrix.**

Parameterized Occupancy Grid as a Base for Perception Applications in ROS Environment

Stevan Stević, Marko Krnjetin, Nenad Četić and Nives Kaprocki

***Abstract*—Method to accomplish autonomous driving can be roughly described by three main capabilities of such vehicle, which are sensing, computing and actuation. Computing as a main component consists of number of different algorithms grouped by their functionalities such as: perception of environment, path planning and following, etc. These functions arose from well-studied approaches and architectures that proved best for self-driven vehicles. Larger community, mostly because of the commercial nature of the subject, does not know more in-depth details of computing platforms and libraries. *Autoware* is a *Robot Operating System (ROS*) based platform that aims to simplify and optimize the development and prototyping of the autonomous systems and features by providing modules and functionalities of autonomous driving to open-source community. In this paper, we extended the perception module of *Autoware* by implementing occupancy grid as generalized and parametrized *ROS* package that can be used as a base for preprocessing in variety of real-time autonomous applications. We also implemented *Proof of Concept* (*PoC*) applications applying *Test Driven Development (TDD)* and *Clean Code* programming principles in context of cutting-edge *Agile* Automotive software development processes. Performances have been evaluated on embedded NVIDIA Xavier SoC and high-end laptops.**

***Index Terms*—automotive; autonomous driving; ROS; Autoware; occupancy grids; Adaptive AUTOSAR; Agile;**

I. Introduction

Self-driven vehicles are having great impact on current society and will do so, on even larger scale, in the following decade. Original Equipment Manufacturers (OEMs) together with the hardware and software suppliers are creating alliances in order to bring fifth level of autonomous driving, where the vehicle is in complete control without the need for human interactions or even control interfaces. Collaboration between OEMs is very unusual in automotive industry because so far they have been competing against each other to profit as much as possible. This is conditioned by the fact, that vehicles at fifth level are becoming complex robotics systems that require multidisciplinary knowledge and skills from different fields to create such machines. One of the most important partnerships – AUTOSAR [1], is working on *Adaptive Platform* [2], which aims to provide standardized foundation for further development of autonomous driving. Pursuit of this requirement is also making changes in cities and roads infrastructure, industries, laws and lifestyle of society to provide support for deployment of these systems in their full potential. These major changes can be justified by the ultimate goal of the autonomous vehicles. The goal is to create safe driving environment, both for pedestrians and passengers, with reduced traffic accidents and death rate.

Looking at autonomous vehicle as a robot system we can dived it in three major segments: sensing, computing and actuation, as depicted in Figure 1. Challenges as the DARPA Grand Challenge [3] with papers that were published from competing teams [4], [5], [6] were they explained similar approaches, have confirmed that autonomous vehicles can achieve autonomous movement with this workflow.

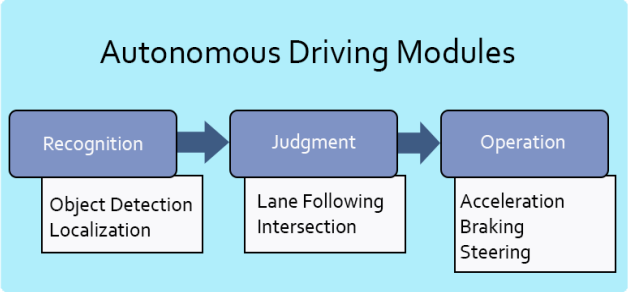

Figure 1. Workflow and examples of autonomous driving modules

Sensing implies usage of large number of sensors like cameras, LiDARs and RADARs for vehicles to be able to gather environmental data and act upon current situation and surroundings. This data is provided to computing modules, which are further divided to scene recognition, path planning, and vehicle control algorithms. Creating reliable image of surroundings in dynamic environment consists of precise simultaneous localization and mapping (SLAM) and detection and tracking of moving objects (DATMO). Many algorithms in this phase use occupancy grids as a preprocessing base for their functionalities. Occupancy grid is a multidimensional random field that maintains stochastic estimates of occupancy state of the cells in a spatial lattice as first introduced and explained by Elfes [7]. Advantages in their usage is reflected by similarities with humans in how environment is perceived,

Stevan Stević is with the RT-RK Institute for Computer Based Systems, Novi Sad and Faculty of Technical Sciences, University of Novi Sad, Serbia (e-mail: stevan.stevic@rt-rk.com).

Marko Krnjetin is with the RT-RK Institute for Computer Based Systems, Novi Sad, Serbia (e-mail: marko.krnjetin@rt-rk.com).

Nenad Četić is with the RT-RK Institute for Computer Based Systems, Novi Sad, Serbia (e-mail: nenad.cetic@rt-rk.com).

Nives Kaprocki is with the RT-RK Institute for Computer Based Systems, Novi Sad and Faculty of Technical Sciences, University of Novi Sad, Serbia (e-mail: nives.kaprocki@rt-rk.com).

better differentiation between moving and static objects, and accurate, real-time representation of dynamic surroundings, also suitable for noisy sensors.

This is followed by decision-making and path planning module where great engineering efforts are made to create more efficient algorithms like [8]. From rule-based and pattern recognition algorithms, to the latest which are relying extensively on artificial intelligence.

Achieving autonomous driving by connecting described components creates large code-base that grows exponentially in complexity. OEMs want to retain good practices that have secured a high level of quality and ultimate software products for years. Through the implementation of the ASPICE standard, and alongside practices like TDD and Clean Code, this requirement is fulfilled. Despite that, in order to meet the challenges posed by the market, they had to adapt software development processes by adopting cutting-edge trends such as scaled agile frameworks and their most influential implementations: LeSS and SAFe in contrast to classical V-model.

In this paper, we implemented simple yet effective library that creates occupancy grids. Library is implemented as a ROS package that can be utilized in different ways with creating nodes that will provide grid data or integrating it with custom nodes already applied in specific applications. In section II, we elaborated papers that have influenced the idea for this paper. Section III presents the solution and explains used software stack. Finally, in last section in order to evaluate usage of this library on embedded platforms in Autoware environment we implemented simple PoC applications and deployed them on embedded SoCs to perform measurements of performance in the real systems.

II. Related Work

Scene recognition manages data fusion from multiple sensors and tends to provide credible information in order for vehicle to be aware of its location and detailed surroundings.

Extensive academic work has been done in terms of vehicle localization and mapping - SLAM. One such solution [9] describes how the map-aided algorithms and classical methods like iterative closest point (IPC) and usage of global navigation satellite systems (GNSS) can be improved with occupancy grids. They solve localization problems imposed by highly dynamic, crowded urban environments and obstacles like trees or buildings that can that interfere with GPS signals.

In [10] and [11] experiments were conducted to explain how to track boundaries using occupancy grids and LiDAR data instead of classical Hough transform or Radon transformation for road segments. Tracking of boundaries plays a crucial role in computational modules to follow. Knowledge of obstacle position is needed when determining logical boundary that represents area through which vehicle can move for creation of local waypoints within path planning modules. Furthermore, this can be used for detection of other vehicles or unexpected obstacles like a running animals or humans crossing the road off the pedestrian crossing.

Free space detection is one of the features required in autonomous parking applications. Interesting research [12] presented how fusion of occupancy grid, created from camera and LiDAR sensors, together with static cameras on parking lot, can be utilized in order to detect parked vehicles and even track movement of pedestrians. Combined with information on free space, autonomous vehicle can park without incidents. Similar solution [13] also addressed detection of parked vehicles but using a different approach. This approach was based on increasingly used classifiers and feed from camera on moving vehicles Preparation work has been done with the test drives and extraction of parked vehicles from frames to create labeled data sets for training of deep convolutional networks.

Artificial intelligence was subject of another work [14] where they have gone a step further and combined occupancy grids and deep convolutional networks to detect and act on moving vehicles.

Discussed papers and many others -, have a wide range of applications and all of them are designed with occupancy grids as preprocessing solution for further implementation of their specific functionalities. We wanted to implement simple generic solution that can be reused in such applications, depending on the nature of approach, to avoid unnecessary waste of effort on re-implementation of same functionality. However, in order for this to be useful, platform that provides comfortable changes in sets of computational algorithms and their communication is imposed indirectly.

Platforms for autonomous driving similar to Autoware also exist, some of them being open-source oriented like Apollo [15] and proprietary ones like NVIDADriveWorks [16]. Adaptive AUTOSAR, however, will probably be the most implemented platform and found in most production-ready vehicles. Platform is oriented towards computational power and connectivity needed to deploy self-driven vehicles. Service oriented architecture makes it very similar to ROS and Autoware and one of the reasons we decided to use these platforms. These platforms are even utilized by OEMs and growing number of robotic projects.

III. Solution

In previous section, we stated the reasons for our decision to use ROS and Autoware. In order to understand their advantages properly, first part of this section covers brief introduction of these concepts. Second part explains the steps of occupancy grids package processing and connection with the rest of the system.

A. Robot Operating System - ROS

Robot Operating System [17] is flexible middleware designed to control robotic systems. Before idea of systems like this, people working on robotic projects often had to reinvent the wheel and implement all components of the system from scratch. ROS provided a way for these kinds of projects to have horizontal architecture. Benefits from

horizontal module organization are seen in code reusability, more efforts spent on optimization and extending of existing layers and focus is on development of new features. Layers are roughly divided in hardware abstraction, middleware and application layers. Furthermore, ROS relies on existing OS and provides structured communication layer for inter-process communication as a main feature. Acts like a *peer-to-peer* distributed system using publisher and subscriber model, as well as service-oriented communication. ROS Master node is main component of the system, responsible for registration and subscriptions of new nodes. Drawback introduced with this principle is the single point of failure, but it is handled in ROS 2 as well as support for real-time systems.

Node in ROS vocabulary represents a single process. Every node has a specific role in the system and communicates with other nodes by broadcasting data on advertised topics, by consuming from subscribed topics or both. ROS offers multilingual client libraries that provide easy integration of nodes with the system. This way, core functionality of most of the nodes is not bound to this middleware and can be reused in other environments, which created flexible and robust platform.

Inter-process communication is done through ROS communication tools - topics, services and actions. These tools have varying types depending on type of data they describe. Types are described using Interface Description Language (IDL), out of which actual code for different language bindings is generated to support multiformity of messages.

Ecosystem represented by ROS, which includes tools, capabilities and large community, created a basis for open-source autonomous platform like Autoware.

B. Autoware

Autoware [18] is an ROS-based open-source platform for autonomous driving developed by Nagoya Institute [19]. Platform architecture is designed to be able to support three main functionalities of self-driven vehicles discussed before. Set of implemented sensor drivers and algorithm nodes made this middleware well suited for urban driving. Necessary functions like 3-D map generation, localization, object recognition and vehicle control are all provided within this platform. Other driving areas can also be supported by easily expanding the functionalities of the platform.

Furthermore, platform is utilizing well-known open source libraries and frameworks like OpenCV or CUDA, which gives us the ability to harness their power with relative ease, and implement complex algorithms and functionalities.

C. Occupancy Grid Package

During the recent years, the occupancy grid framework that was out of the scope because of high resource demands, started to find its use in perception applications. Cause for this change is found in increased computing power and memory limits on embedded platforms introduced with the use of SoCs.

Objects in grids are logical representation of environment that imposes the space affected to be split and that every field carries information about probability of object in that field. This can be utilized in different applications, but they all need different parameters in order to harvest the full benefits.

We implemented ROS package that takes input parameters like dimensions and center of the grid and size of a single cell to create function specific occupancy lattice. In addition, source of the data for the processing can be configured by specifying the correct ROS topic. Library processes data in point cloud format. Point cloud represents a set of data points in space, scanned and produced by lasers, which are LiDARs in this case. Special Point Cloud Library (PCL) [20] is used by the package to optimize processing of these 2D/3D point clouds.

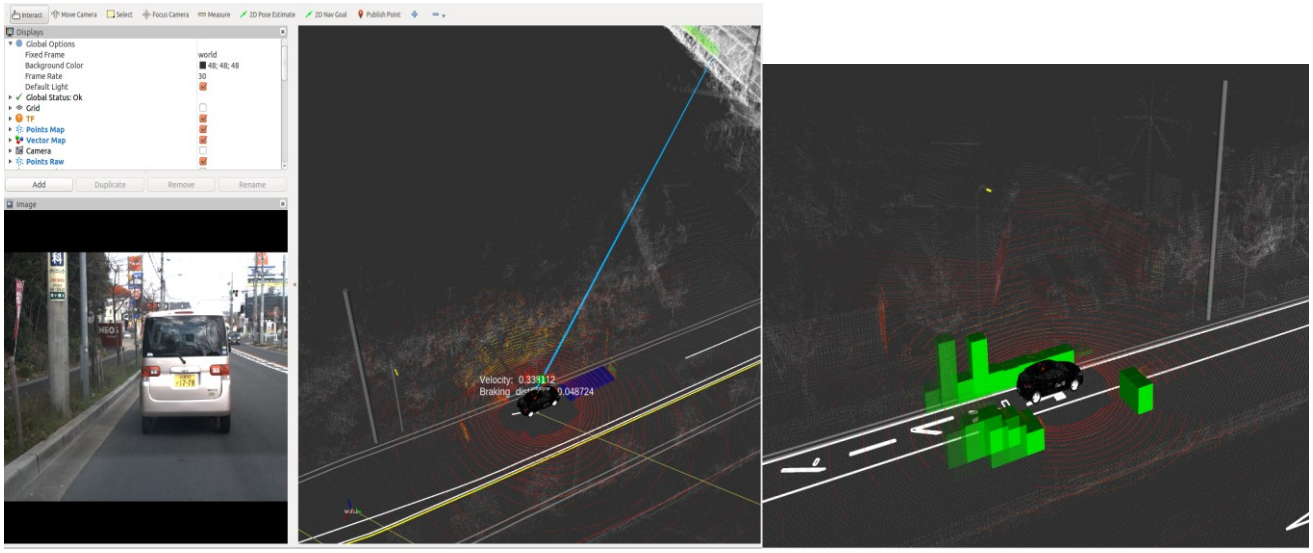
After obtaining data for processing, coordinate transformation of point cloud is required. Center of the recorded point cloud is represented by LiDARs placement, which can be on different parts of the vehicle depending on purpose and area aimed to cover. In order for fusion algorithms to provide realistic model of surroundings, the data processed, has to have uniform coordinate system for correct calculations. This base coordinate frame is also configurable and transforamtion is performed to put the points in given coordinate system.

Computing of probabilistic value for every cell can be resource consuming depending on LiDAR precision, so in order to prevent this from happening point cloud is filtered to region of interest (ROI) which is constructed based on given parameters. Creating ROI consist of two parts which are reduction of point cloud to fit the dimensions of the grid and extraction of ground points. Reducing size was effectively implemented with the usage of previously mentioned PCL that offers range conditions. Conditions were set on all three dimensions to create pass filters. Next step is extraction of ground points as they can affect the accuracy of detection. We used two-step filtering [21] with angle and distance-based filters. This way besides extracting the valid points, we also provided information of ground points, and this could be effectively used for free-space detection.

Preprocessed cloud is the input for the next phase where occupancy grid is created. Probability of objet found in a cell is expressed as a sum of points affected by the cell with the possibility of defining the threshold. We used vector to store the sum of the points and represented cells as vector indexes. Indices are simply calculated after diving current point positions with the cell size. To avoid negative indices whole matrix is displaced to positive range. At the end of processing library can provide occupancy grid structured as a vector carrying information about point occupation in every cell with displaced center and information about ground points. In next section with utilized this data through proof of concept applications.

IV. Evaluation

In order to properly evaluate library grid package in context of automotive development we utilized continuous integration tools in combination with TDD methodology to implement demonstrative ROS nodes working in Autoware environment. Applications also enabled us to execute performance measurements. As LiDARs work on 10MHz - 100 MHz we



a) b)

Figure 2. a) Stopping distance node that uses occupancy grid with center displaced from vehicle's rear axis to detect obstacles
b) Visualization of occupancy grid in context of SLAM

excluded this factor and defined measurements as end-to-end time required to process point cloud messages from rosbag to useful data like probabilistic value of detected object or free space, which is represented by extracted ground points.

Rosbag is a file used to log timestamped messages from all topics and it can be used to reply the scenarios for analysis and debugging. We used open-source visualization tool RViz while implementing perception applications as this tool provides offline visualization of the sensor data from rosbag file while other nodes can process the data as if they are part of the experimental system.

Two applications seen in Figure 2 are implemented to test the library. For the stopping distance application, we implemented the separate node that would publish the grid data. Application was subscribed to the topic advertised by created node and implemented calculations of distance required to stop. Simplified logic is based on vehicle velocity and provided data of object probability in front. Other application was set in context of SLAM and integrated library in the node itself. Both of them published different kind of markers also seen in Figure 2 in order to visualize and informally validate the process in RViz.

During the development as stressed before we wanted to create complete automotive environment, which requires usage of continuous integration tools, high code coverage, traceability and other parts of the automotive processes. Usage of Docker containers with Jenkins as a CI tool and Autoware environment enabled us to illustrate part of the real automotive development workflow on small-scale project.

The goal of these measurements was to gain sense of effectiveness of the library in real embedded automotive hardware as realistic as possible. Furthermore, to illustrate power of today's SoCs, defined measurements were conducted on NVIDIA Drive PX embedded platform with 2xXavier SoCs. In contrast to this, high-end laptop with i7-7500U processor, 16GB of RAM and GeForce 940MX dedicated GPU was used for comparison. Average measurement results are displayed in Figure 3. As expected, with faster execution on embedded platform, we can understand why, the resource consuming autonomous driving can be achieved with current technology.

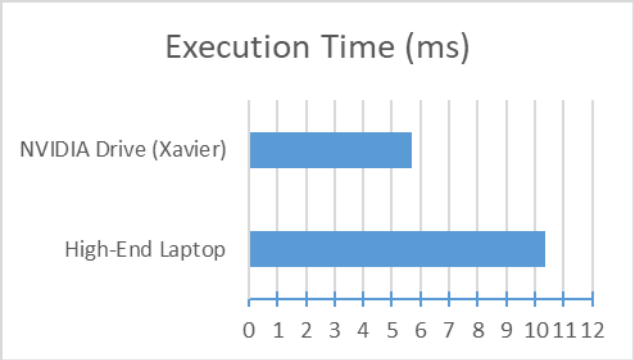


Figure 3. Average execution time of occupancy grid library on different platforms

V. Conclusion

Main goal of this paper and research has been to reflect current trends and problems of the automotive industry. Implementation of different sorts of algorithms is just one aspect of the autonomous driving, but many neglect importance of conducting all work and experiments under demanding automotive processes and principles. Ultimate reason for their existence, when correctly realized, is to facilitate development and minimize human error in the

process in order to deploy safe and secure products to the market. In this paper, we used good practices of automotive development, by using TDD methodology found suitable usage of CI tools, and covered part of the evaluation process. Furthermore, we briefly mention new agile processes that are coming to automotive industry and aim to merge best of classical and agile frameworks.

However, focus was to illustrate importance of modular autonomous platforms that is why we used ROS and Autoware platform to implement simple occupancy grid library wrapped in a ROS package. Occupancy grid carry probabilistic information of object presence in their scope, which makes them suitable both for mapping and detection. Implementing them as part of Autoware makes them usable in many perception applications, which are part of scene recognition module.

Finally, we evaluated this simple occupancy grid module by implementing pair of perception applications and measured times needed in order to obtain valid occupancy grid.

Simulation of humanoid movements of the NAO robot using the Virtual Robot Experimentation Platform V-REP

Slađan Kantar, *School of Computing, University Union,* Miloš D Jovanović, *Institute Mihajlo Pupin, University of Belgrade*

***Abstract*— This paper is based on the use of a free virtual robot experimentation platform (V-REP) in order to design and test humanoid movements of the NAO robot. The simulation platform contains a complete NAO-robot model with integrated sensors. The document lists the necessary configurations of the environment to simulate the behavior defined in the tabular document. In addition, several scenes have been implemented, in various ways, to illustrate the platform's capabilities used for simulation. All examples are freely available to readers.**

***Key words*— Simulators, V-REP, Humanoid robot, NAO robot**

I. INTRODUCTION

Robotics, as a multidisciplinary field, has been introduced to all levels of education in the last few years. Automation, informatics, electronics, mechanics, physics and mathematics are just some of the sciences which learned in robotics. It is precisely this fact that makes robotics very versatile from a pedagogical perspective. Also, the scope of this field allows the experiments within it to be performed at very simple levels (simple motion, rotation, data input from sensors) as well as at much more complex ones (much more demanding experiments such as simultaneous localization and mapping (SLAM), navigation with image processing and the like). [1]

Until just a few years ago, the word robot was associated with a large and costly machine, which in many cases had to be connected to a computer with cables. This was one of the main reasons why robots stayed away from classrooms. Today, it is very easy to make a small mobile robot with cheap actuators, sensors, motors and built-in systems. Currently, mobile robots are used in many courses in the fields of IT, automation, mechanical engineering and mechatronics.

In most research areas, simulators are very important tools for testing the theorems, ideas, designs, before implementing a real experiment. In the field of robotics, simulators are even more important given that advanced robots are still expensive and there is no possibility that all students can perform their experiments on one device simultaneously. Currently, there is a great number of simulators for different robotics fields, and they all give very good results. Some of the most used ones are: ARGoS, Webots, Gazebo, RFCSIM, and V-REP. [2-8]

The V-REP simulator is one of the most used simulators. This simulator is a versatile, scalable tool for creating 3D simulations in a relatively short period.

The V-REP simulator contains an integrated development environment (IDE) based on a distributed and scripted architecture: each object within a unique simulation can include a script related to it; all scripts are executed simultaneously. The V-REP simulator comes with a large number of examples, models of robots, sensors, actuators for creating a virtual world and interacting with it. Also, the tool allows the creation of new, specific models.

This paper describes a simple simulation of the movement of the NAO robot using the V-REP simulator. The rest of the paper is organized as follows: Section 2 gives a better insight into the used simulator (V-REP); Section 3 describes a humanoid NAO robot; Section 4 shows the design, implementation, and results of the study; Section 5 gives the main conclusions and suggestions for further research.

II. THE V-REP SIMULATOR

The Virtual Robot Experimenting Platform (V-REP), which is the literal translation of the full name of this tool, is a versatile and scalable environment for the simple development of 3D simulations. The simulator was created in 2010 and has been experiencing tremendous growth in the last few years. Today, this tool is one of the most used simulators in education in the field of robotics (the manufacturer offers a free license for education purposes). [9]

The V-REP contains an integrated development environment (Figure 1) based on a distributive control of architecture: each object/model can be individually controlled using a script, an accessory (plugin), a robotic operating system (ROS) node, a remote API client, or some other utility tool. Controllers can be written in different languages such as Java, Lua, Matlab, Octave or Urbi.

The V-REP comes with a large number of examples, a robot models [10], a sensor, actuators for creating a virtual world and interacting with it in real time. Figure 1 shows one of the examples: a Nao robot with two cameras and images of the surroundings which the cameras read.

Milos D Jovanovic – Institute Mihajlo Pupin, Volgina 15, 11000 Belgrade, Serbia (e-mail: milos.jovanovic@pupin.rs).

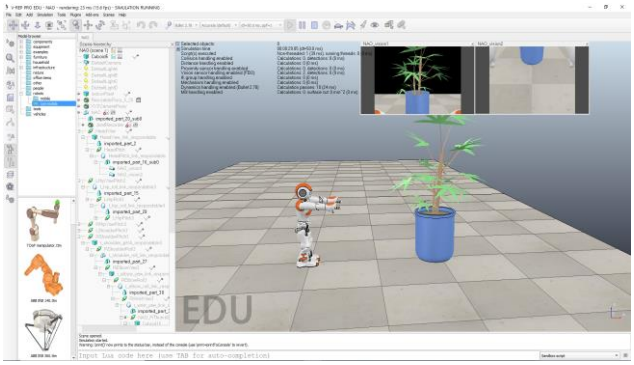

Fig. 1. The layout of the integrated development environment of the V-REP. The figure shows a scene including a NAO robot and an arbitrary object. In this figure, we can also see information that are registered by sensors (cameras) on the NAO robot.

As the NAO robot is one of the more famous humanoid robots, the V-REP platform, in its factory version, contains the model of this robot. Considering this advantage, the simulation for the NAO robot was designed and developed exactly by this simulator. The following section describes the model details.

III. THE NAO ROBOT

NAO robot is a programmable, humanoid robot 58 cm high, developed by the French company Aldebaran Robotics in 2006 (Figure 2). The NAO robot has the ability to move, to see with visual sensor, and to hear with audio sensors integrated into it. In addition to the above-mentioned features, it can talk. Until a few years ago, the NAO robot was highly known in the field of education. It has been officially used in more than 70 countries. [11]

Fig. 2. The look of the NAO robot. The figure shows two robots where several degrees of freedom can be detected

A. *Key components of the NAO robot*

Nao is a small humanoid robot with a simple combination of hardware and software [12-13]: sensors, motors and the NAOqi operating system which includes a software for controlling. The NAO robot has several key components:

- the NAO robot has a body with as many as 25 degrees of freedom. The key elements are electric motors and actuators (figure 3).
- the NAO robot contains a network of sensors consisting of two cameras, four directional microphones, a sonar remote sensor, two IR emitters and receivers, one inertial board, nine touch sensors and eight pressure sensors.
- the NAO robot has several communication devices, including a voice synthesis, LED lights, and two HiFi speakers. As such, the NAO robot can hear, talk and blink with the lights.
- the main processor unit is the INTEL Atom 1.6 GHz CPU, which is localized inside the head and run by the Linux kernel.
- the NAO robot also has a second processor in its torso.
- the NAO robot is run by a 48.6 Wh battery which allows the NAO robot up to 1.5 hours of fully independent autonomy.

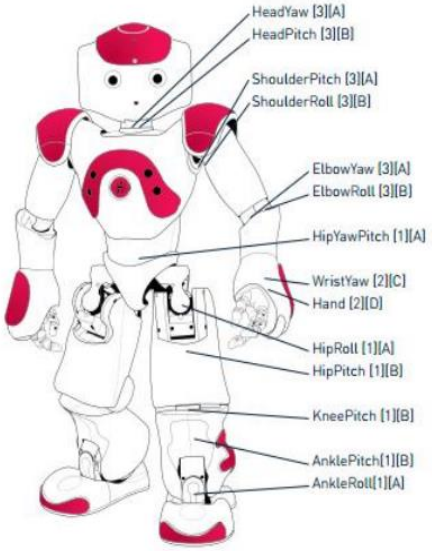

Fig. 3. Joints for NAO robot

B. *The NAO robot model in the V-REP simulator*

The NAO robot model, within the V-REP simulator, contains all the sensors and actuators of the real robot listed in the previous chapter. The model also contains an example of the use of the robot. The example shows a simple robot walk along a closed square path within a scene. From the example, one can clearly see how each of the degrees of freedom is manipulated.

IV. IMPLEMENTATION AND RESULTS OF THE STUDY

The basis of each model within the V-REP environment consists of Joints and Paths that can be assigned to each of the angles. Paths provide for defining of the complex movements of each object.

Also, the basic model of the NAO robot comes with a predefined script for scene recording, as well as the generated

sequence of the joints' positions that allow the robot to walk. By defining the paths, or by associating them with the joints, it is possible to define arbitrary movements, and the position of the joints can be saved in a text document.

Since most existing simulators allow the user to export the state of each of the degrees of freedom at certain time points, the aim of this paper was to implement a library for simulating the movement of the NAO robot defined in the text file. This is exactly what will enable us to run a previously defined simulation in another simulator or on some other way. [14-24]

A. *The appearance of the file with the positions of the joints*

Each line inside the tabular document contains information on each of the degrees of freedom. An example of a tabular document is shown in Figure 4. [32]

Time	RHipYawPitch	LHipYawPitch	RSho
0	0	0	
1.64	-0.366584	-0.366584	
3.12	-0.253067	-0.253067	
4.28	-0.340507	-0.340507	
5.92	-0.0551819	-0.0551819	
6.76	-0.0551819	-0.0551819	
7.52	-0.0551819	-0.0551819	

Fig. 4. Appearance of the file containing the sequence of behavior of the NAO robot. In the picture, we see some of the degrees of freedom defined in Figure 3.

As the NAO robot model within the V-REP environment comes with a predefined script for recording the condition of the joints, the file itself can be made using the simulator itself. The simulations performed in this work are exported from the scenes defined in the Choreography tool, made by the NAO robot manufacturer, which is unfortunately not free.

Note that, at the initial moment, each of the degrees of freedom has an initial value of 0. At that point, the robot has an upright position (Figure 5).

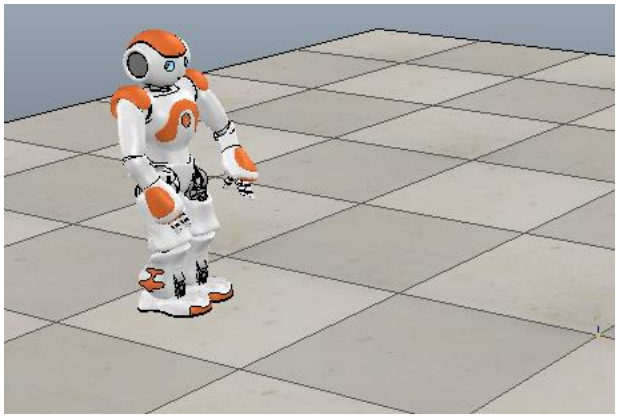

Fig. 5. The initial position of the NAO robot at the moment of t = 0

B. *Creating a file within the V-REP environment*

Within the V-REP simulator, the model of each robot consists of joints and sensors arranged in a tree-structure for easier manipulation. In addition to the existing elements, manually defined paths can be added within such a structure. Paths are added by inserting "Path" objects, or by connecting them to some of the joints.

There are two predefined paths, circular and rectilinear, but the tool allows the creation of complex paths by defining arbitrary points.

An example of a circular path assigned to the neck of the NAO robot is shown in Figure 6.

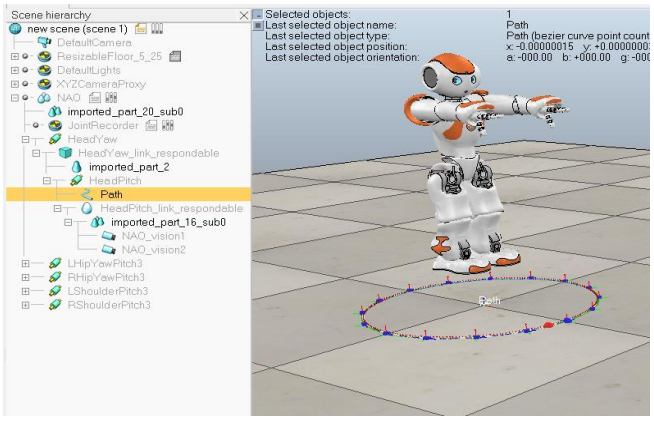

Fig.6 The circular pathway assigned to the joint of the neck of the NAO robot. Within the tree structure we see the Path object, in the hierarchy positioned as a Child to the joint that we want to manipulate.

C. *Process of sequence execution*

Controlling the model within the environment is performed by the scripts written in the LUA programming language. For the purposes of this paper, a script for loading the positions of the joints was written, and their execution. The process of executing the sequences defined in the file is in Figure 7.

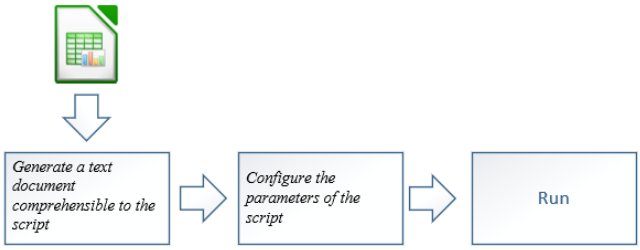

Fig. 7. The step diagram required to perform the simulation defined in the tabular document.

D. *Generating a text document comprehensible to the script*

The main reason for the existence of a tabular document is that it is easy for a man to manipulate it. The LUA programming language does not support simple management of tabular documents; a script is written in the Python programming language, which transfers the tabular document into a plain text document, where each cell is in a new row. With this simple script, available on the GitHub page [26], we

create a text file that is understandable to the NAO robot model within the V-REP simulator.

E. Configuring the parameters of the script within the simulation and starting the simulation

The script defined within the scene, as an argument, receives a path to the file that contains information about the position of the joints, and executes the movements defined therein. Right before starting the simulation, it is necessary to change the *filePath* parameter so that it has a value of the path to the generated file [27]. After setting the path, the simulation is ready to start. [28]

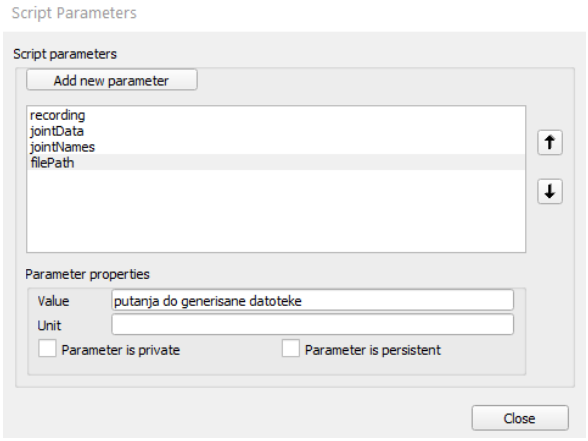

Fig. 8. An example of the window for changing the script parameters.

F. Case studies - waving and push-ups of the NAO robot

For the purposes of this paper, two humanoid movements were implemented: the waving of the NAO robot (Figure 9) [29-31] and push-ups of the NAO robot (Figure 10). [31-33]

Waving is one of the simplest movements of the NAO robot. The basis of this study is the movement of two joints, left shoulder and left elbow, with minimal movement of all other joints in order to gain effectiveness.

The NAO robot waving sequence is generated manually by changing the movement degree for low values. It was noted that this approach to generating the sequence was very slow, and it is almost impossible to generate sequences of more complex behavior by this method.

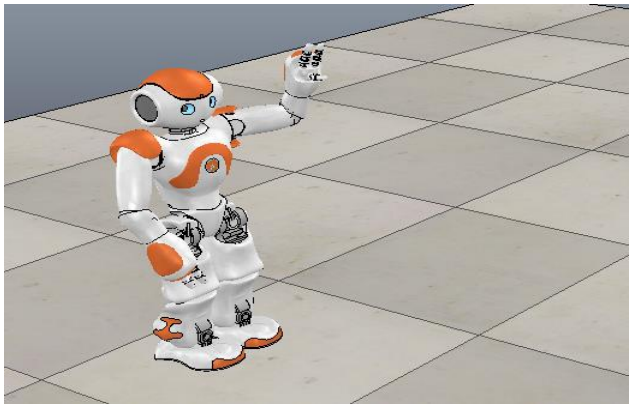

Fig. 9. An example of greeting (waving) of the NAO robot

Making the NAO robot do push-ups is a more complex study. The entire scene consists of several parts: getting into the push up position, doing push-ups, return to the starting position.

The sequence used for this study is extracted from the scene implemented within the Choreography tool. Choreography is one of the most popular simulation tools for NAO robots, so it is possible to find a large number of ready-made simulations on the Internet.

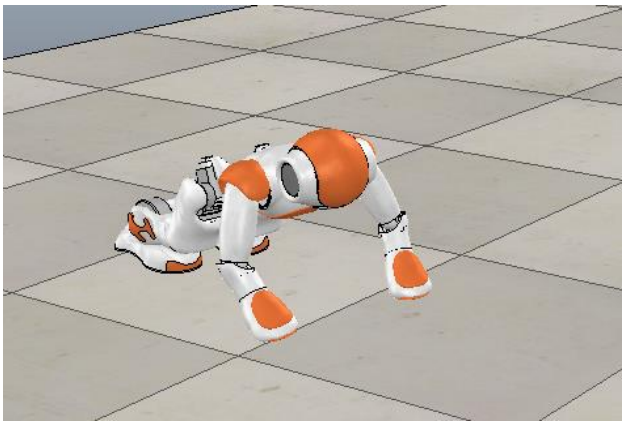

Fig. 10. An example of a NAO robot doing push-ups.

After starting the scene within the Choreography simulator, one can see the great advantages of the V-REP simulator. An example of how the identical simulation within the Choreography simulator looks is shown in Figure 10.

The greatest advantage is given to the influence of gravity, which within the V-REP environment gives a more realistic view of the real behavior of the NAO robot (the difference can be seen in Figures 10 and 11)

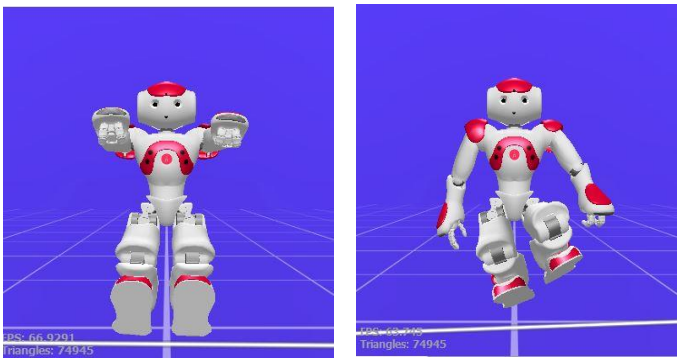

Fig. 11. An example of a NAO robot doing push-ups within the Choreography environment

V. CONCLUSION

In this paper, examples of NAO robot simulation using the V-REP simulator are presented. The examples show simple waving and simulation of push-ups on the original NAO robot model, which comes with the V-REP platform.

As a result of the development of this simulation, tools

were created that enable execution by defining behavior within a tabular document. By following these steps, it is possible to run many simulations without changing the code within the V-REP scene.

As a further research, the plan is to start one of the simulations created in the V-REP simulator on a real robot, and detect the observed differences.

Benefits of residual networks in reinforcement learning using V-rep simulator

Aleksandar Pluškoski, Igor Ciganović and Miloš D. Jovanović

***Abstract*—There are two major problems in the reinforcement learning. One is the stability of the training algorithm. The other is the limited accessibility of the real world training. Reinforcement learning algorithms are notoriously unstable while training because of the very complex loss functions. Residual networks offer smoother gradient descent and thus more stability while training. The other problem is the practicality of the real world training. The reinforcement learning is used for planning and problem solving. While game-like environments are enough for the proof of concept algorithm benchmarks, practical implementation usually requires highly specialized and usually very expensive equipment. It is not practical to have the agent train on the equipment that can easily be damaged. Also the speed and the parallelizability of the physical robots are the additional limiting factors. All these limitations can be addressed by using the simulator. However, setting up the simulator to be used with the external reinforcement learning agent is not a simple task. The solution presented in this paper illustrates the process of setting up the V-rep simulator and presents the results of testing the residual network versus the simple convolutional network.**

***Index Terms*— Artificial intelligence; AI; neural network; reinforcement learning; simulation; v-rep; convolutional network; residual network**

I. Introduction

Reinforcement learning is the process of mapping states to actions. The problem that the agent is trying to solve is usually modelled as a Markov decision process. The goal of the reinforcement learning algorithm is to learn the transitions between the states, as described in [1]. Said states represent the input to the agent and are usually observed through some sensor device. The output is the action that the agent should take to achieve some predetermined goal.

The process of learning is modelled on how we learn by trial and error. The idea is that the agent should try many different solutions and observe the feedback, in a form of a predetermined reward, from the environment. Using that feedback the algorithm should try to find optimal solution by reinforcing the good behaviour and discouraging the bad [1].

Environments with finite amount of states and transitions could be solved using simple tabular methods. When the observation and action spaces are continual the only solution is to introduce the deep reinforcement learning. In deep reinforcement learning instead of a table, the neural network is used to approximate the function that maps points in the observation space to the points in the action space.

In contrast to supervised and unsupervised learning where the agent receives the feedback after every execution, the reinforcement learning agent can execute many steps before any, positive or negative, reward is observed. Reward engineering is the whole distinct field of study in itself and the details are beyond the scope of this paper. After observing the reward the algorithm propagates that reward backwards through time steps. The reward and the state – action pairs are then used as an input for the gradient descent algorithm used to train the neural network.

The new problem which exists in the reinforcement learning but not in the other fields of machine learning, defined in the [2], is the problem of balancing exploration and exploitation. The agent should try to maximize the reward but at the same time it should try to explore and find better solution.

Taking into account sparsity of the reward, complexity of the learning method, possible partial observability and stochasticity of the environment and other problems, it is easy to conclude that the reinforcement learning algorithms can be very unstable. This is described in [3] and a possible solution is presented. In practice that means that the results are often not repeatable. Running the same setup multiple times often yields different results. Often the training gets stuck in local optima or just fails to find any solution.

Many different approaches to partially solve this problem have been implemented, like in [3, 4, 5]. The solution presented in this paper tries to improve on the stability of the training process by making the neural network itself more stable during the training.

It had been shown in [6] that residual neural networks offer more stability during the training and improve capacity of the neural network by allowing much greater depth. The benchmark of using the residual neural network versus classical convolutional neural network in the reinforcement learning algorithm is presented in this paper.

Since the reinforcement learning is used to solve planning problems, it is logical to apply it to the field of robotics. Also it is easy to conclude that trial and error experimentation on the expensive and complex robotic systems is not acceptable. Because of that different tools in the form of simulators have been developed. Although these tools have been much improved in the recent years, it is still not trivial to set up the simulation for the particular problem. This is described in greater detail in [7].

Based on the surveys of different simulators [8, 9] it was decided that the Coppelia Robotics V-REP [10] simulator is to be used for the solution presented in this paper. The important factor that was taken into consideration was the existence of the Python bindings. Since the simulator will

have to be controlled from the external framework. An illustration of the aforementioned simulator can be seen in the Fig. 1.

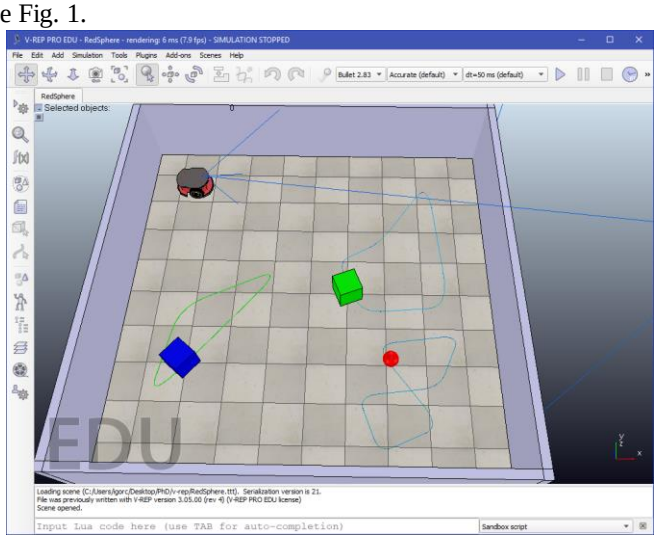

Fig. 1. Overview of the simulator main window.

II. Related work

Stephen James in his Ph.D. dissertation, "3D Simulated Robot Manipulation Using Deep Reinforcement Learning" [7], describes the use of the V-REP simulator with the reinforcement learning algorithm. The algorithm in question is the deep Q learning algorithm. The paper shows, among other things, the effects of the sparse reward on the training process.

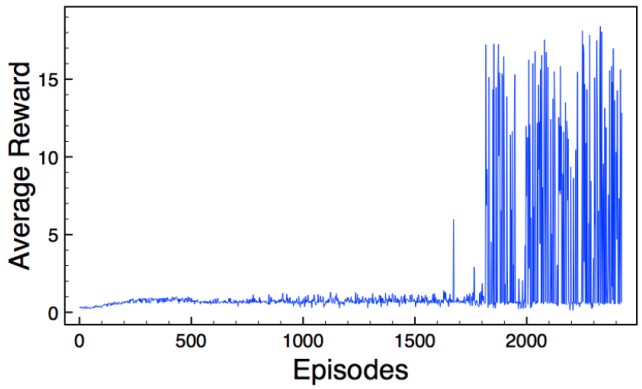

Fig. 2. Average reward by episode in the deep Q learning algorithm. (Taken from [7].)

It can clearly be seen in the Fig. 2 that it takes a lot of time for the agent to find the solution and to start optimizing it. The Fig. 2 shows that only after nearly 1800 episodes the agent finds the expected solution. Taking into account that one episode is the complete simulation run it is easy to conclude that the time needed to find the solution can be a limiting factor. Considering that each simulation run can last up to couple of minutes. The paper further states that the performance and delay of the V-REP simulator proved to be the limiting factor. Hence it was decided that the custom simulation was to be developed in the Unity 3D engine.

Although the paper states that the Python bindings were used to control the V-REP simulator it does not go into great detail in describing how this was used. The solution in this paper tries to detail the setup of the simulator of the use with the reinforcement learning algorithm.

The team from OpenAI led by John Schulman developed the proximal policy optimization algorithm [5] to try to address the issue of the training stability of the reinforcement learning algorithms. In their paper they show that the clipping of the gradients during the gradient descent can have beneficial effects on the stability of the training process. Because reinforcement learning approximates the target of the gradient descent, based on the observed reward, the direction of the target can vary significantly between the iterations. By clipping the gradients a much smoother trajectory can be achieved. Also because the steps taken during the gradient descend are much smaller, samples can be used multiple times. This also gives the better sample efficiency of the algorithm.

The team from Microsoft led by Kaiming He in their paper "Deep Residual Learning for Image Recognition" [6] present the solution to the vanishing gradient problem when training very deep neural networks. The gradient becomes smaller with every layer it passes during the back propagation. After certain number of layers the gradient becomes almost zero and the network becomes impossible to train. To address this issue afore mentioned paper introduces the residual network.

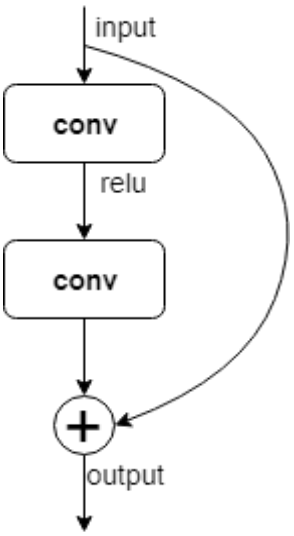

Fig. 3. Diagram of the residual block.

The idea is to divide the convolutional network into blocks. Each block consists of couple of convolutional layers. But the difference is that each block also has its input connected directly to the output as illustrated in the Fig. 3. By building the network like this, the gradients have a way to flow to the deeper layers. On the other hand, all the convolutional layers are still present and the capacity of the network is preserved.

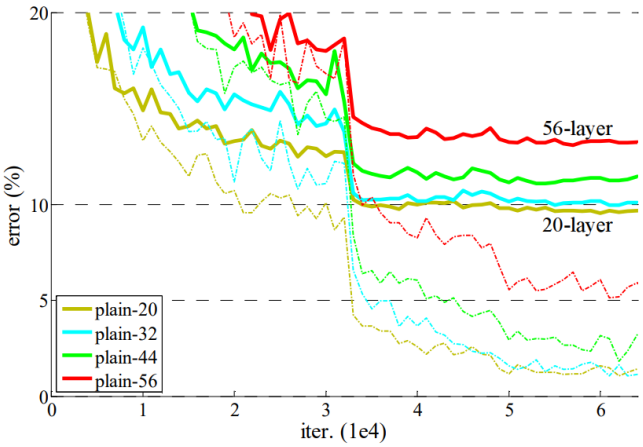

Fig. 4. Convolutional network CIFAR-10 training (dashed lines) and testing (solid lines) error. (Taken from [6].)

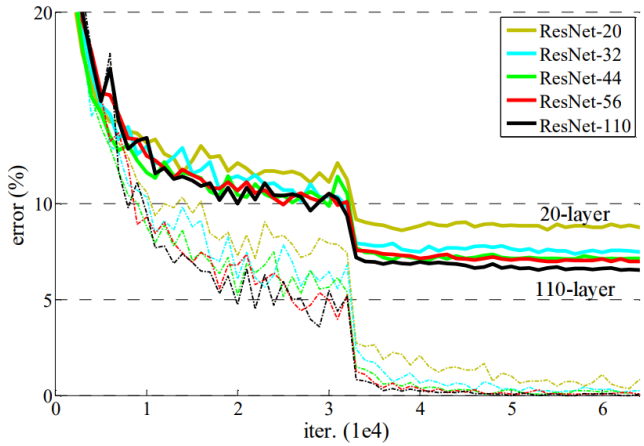

Fig. 5. Residual network CIFAR-10 training (dashed lines) and testing (solid lines) error. (Taken from [6].)

The difference in the learning capacity and the achieved accuracy is illustrated in the Fig. 4 and 5. It can be seen that after around 20 layers of network depth regular convolutional networks start losing accuracy with increased number of layers. In contrast residual networks continue increasing capacity with added depth. Although with the diminished returns after around 56 layers. Suggesting that in order to achieve further improvements the network architecture should be revised.

III. Simulator Setup

When designing the environment for the use with the reinforcement learning algorithm, the inner workings of the algorithm should be considered. Usually the agent will be developed using third party library (i.e. TensorFlow). Because of that the simulator should allow the communication with the external applications. Also, many more efficient algorithms allow for the parallel execution of the replicated agents. Because of the way the reinforcement learning algorithms separate experience recording and learning tasks and the former is much faster than the latter, the simulator should allow for the simulation to be paused and resumed.

In particular the simulator should allow external application to run and stop the simulation, read the data from the environment (sensors and environment variables), write to the actuators and control the execution of the simulation step by step.

Coppelia Robotics V-REP simulator covers all the functionality that was needed for the experiment presented in this paper. They provide the Python bindings for the communication with the external applications. There is no need for any setup on the side of the simulator. All the settings can be provided through Python bindings and the command line parameters. However the V-REP simulator can be used to build the simulation. Although objects in the simulation can be instantiated from the Python code, it is preferable to use the graphical interface to design the scene.

On the other end, the Python language was decided to be used for the solution presented in this paper. Coppelia Robotics provides the library with Python bindings. Three files are needed to be copied to the project working directory. Namely "remoteApi.dll", "vrepConst.py" and "vrep.py" which can all be found in the V-REP installation directory.

Everything else is done through code. Considering how reinforcement learning algorithms run multiple parallel actor tasks, it was decided that it was necessary to have the functionality to start, stop and reset the simulator from the algorithm. The idea being that the learning algorithm should be able to spawn as many workers as needed and control them to collect the experiences (data points). Using Python "sub-process" library it is possible to execute console commands to run the simulator with the command line arguments. Namely "-h" flag that makes the V-REP run headless (without rendering the window) and "-gREMOTEAPISERVERSERVICE_<PORT>_FALSE_TRUE" flag that sets the desired port for the TCP communication, enables or disables remote debugging and triggers. Since it is expected that multiple instances of the simulator will be running in parallel, each of them needs a unique TCP port to communicate with the agent. Also the path to the file containing the simulation scene should be provided and it will be loaded automatically when the simulator process starts. By running the simulator in this way it is possible to run multiple instances locally or remotely even with different simulation scenes.

After the simulator has been started the agent needs to establish a TCP connection to the server running inside the simulator. The Python bindings provide this functionality. Namely the function "simxStart" establishes the connection to the provided IP address at the provided port. After the connection has been made the simulation should be configured to run in the synchronous mode using the "simxSynchronous" function. This allows the external application to run the simulation one step at the time. This is done using the "simxSynchronousTrigger" function, which when called, progresses the simulation to the next step. Then the application can start executing the simulation by calling the "simxStartSimulation" function.

When the simulation is over, the application should first call "simxStopSimulation" function to stop executing the simulation, and only then "simxFinish" to disconnect the TCP connection. After the simulation is closed the process running the simulation should be terminated. During the experiment presented in this paper it was determined that the best way to implement simulation reset functionality is to stop the simulation, terminate the process and start it again.

When the simulation is running it is possible to get the handles to all the objects in the simulation scene, which can then be used to read and write all the relevant variables in the simulation. Detailed explanation of controlling the objects (robots in this example) in the simulation is beyond the scope of this paper. However during the experimentation it was determined that when reading or writing simulation variables "simx_opmode_oneshot" operation mode should be used even though the documentation does not suggest doing this [10], because the other modes either include blocking calls or buffering of the values. Since the simulation is running one step at the time there is no need neither for blocking nor for buffering.

IV. Residual Network Benchmark

With the simulator set up, it was possible to start implementing the intelligent agent for controlling the robot in the scene. The first step is almost always designing the

neural network. Since the reinforcement learning does not have the wide spread practical use because of the training instability, majority of the solutions are proofs of concepts for the learning algorithms. Almost all of them use very simple neural networks because the capacity of the network is not of the great importance. However it has been shown that using the deeper networks can have beneficial effect on transferring the learning between the tasks as described in [4]. As it was stated earlier [6], using the residual neural networks allows for the training of deeper architectures and offers better training stability.

The idea behind this paper was to benchmark the stability of training residual neural network in comparison to the classical convolutional neural network. Since the experiment should test only the stability of the network devoid of the influence of the algorithm, it was decided that simpler (and more stable) supervised learning algorithm should be used.

The human operator would control the robot and the issued commands together with the readings from the sensors on the robot would be recorded. These would then be used as training data for the supervised learning algorithm. Details of this methodology can be found in the paper [11] "Autonomous car driving - one possible implementation using machine learning algorithm".

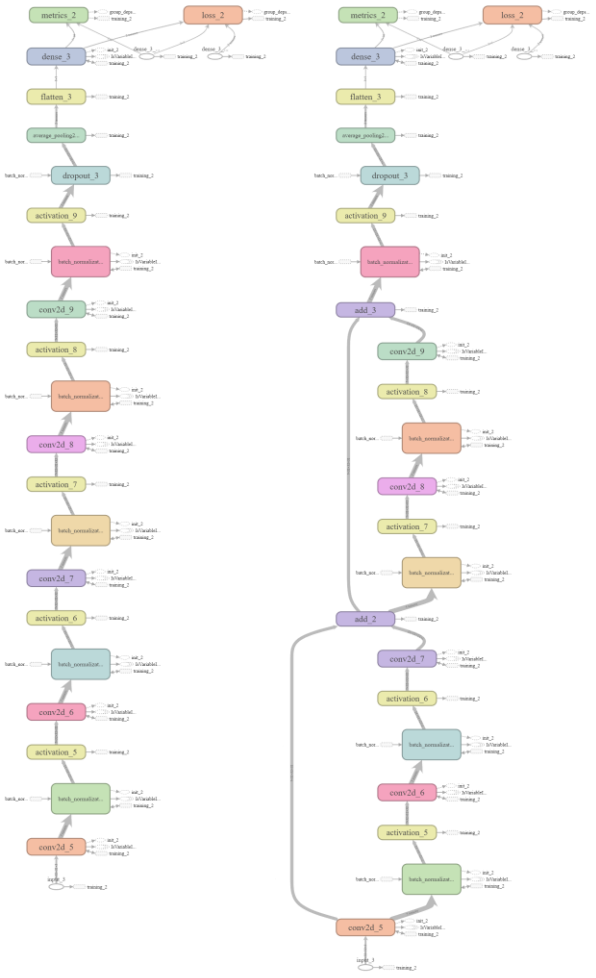

Fig. 6. Diagram of convolutional (left) and residual (right) neural networks 2 residual blocks deep.

With the data collected, two neural networks were constructed, the only difference between them being that one had the skip connections of the residual architecture, illustrated in the Fig. 6. The networks were first trained without the residual blocks to test the validity of the architecture. Then the residual blocks were added one by one and after each step the networks were trained and results recorded. Each residual block consisted of two batch normalization layers and two convolutional layers. In addition to those layers the residual network also had the input of each block connected directly to the output of that block. The testing was done up until 12 blocks, giving 25 convolutional layers in total. During the testing it was decided that going beyond 12 residual blocks was impractical due to hardware limitations.

The training was done with the same dataset and the same number of iterations (epochs) each time. Taking into consideration that the true potential of the residual architecture is in training the networks with more than 50 layers, it can be seen in Fig. 7 and Fig. 8 that the difference exists even with shallower networks.

The experiment was repeated four times. Two times on the local machine and two times on the Google Colaboratory platform [12] to avoid the effects of hardware limitations on the testing results. The results were then averaged for both platforms.

Fig. 7. Values of the loss on the testing dataset.

The Fig. 7 shows the expected decline in the loss value with the increase of the network depth. Also it can be observed that the rate of decline is considerably smoother for the residual network than the convolutional one. This can be seen in particular with the network depths of 5 and 6 where the convolutional network simply failed to converge to an optimal solution. The results shown in the Fig. 7 were obtained on the testing dataset (from the standard 20:20:60 testing: validation: training division of the dataset) after the networks were trained.

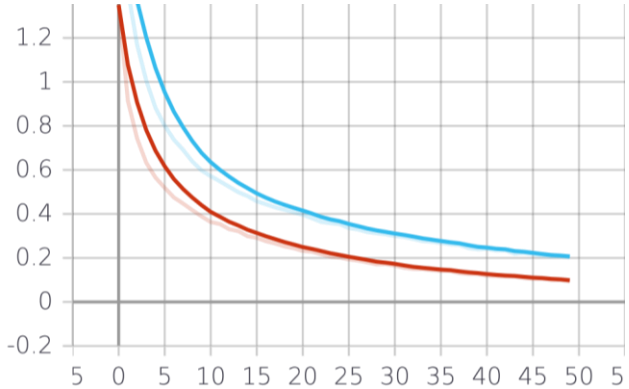

Fig. 8. Values of the loss on the training dataset recorded every time step for the convolutional (blue) and residual (red) networks with the depth of 12 residual blocks.

The Fig. 8 and Fig. 9 show the results of the loss metric on the training and validation dataset respectively on the per epoch basis. It can be seen that the residual network (drawn in red in both charts) converges faster, much more steadily and to a lover optimal value.

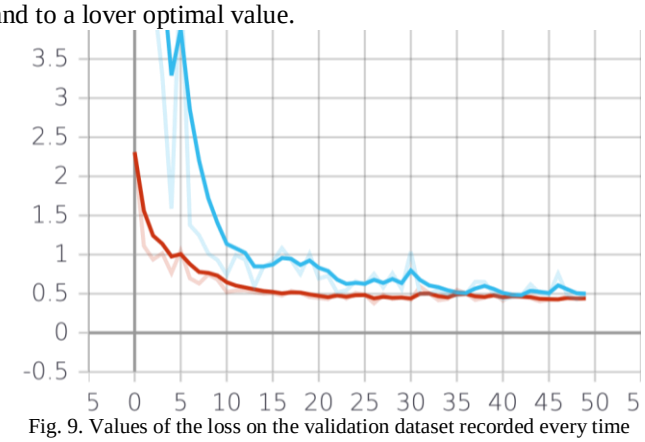

Fig. 9. Values of the loss on the validation dataset recorded every time step for the convolutional (blue) and residual (red) networks with the depth of 12 residual blocks

To calculate the loss value the categorical crossentropy function was used. It is a standard classification loss function. It is used when there is more than 2 categories. The formula for calculating categorical crossentropy is

$$H = -\frac{1}{N}\sum_{i=1}^{N}\sum_{c=1}^{C} 1_{y_i \in C_c} \log p[y_i \in C_c].$$

Where N is the number of samples in the dataset, C is the number of classes, $1_{y_i \in C_c}$ is 1 if the i-th sample belongs to the c-th class or 0 otherwise and p is the predicted probability of i-th sample belonging to the c-th class.

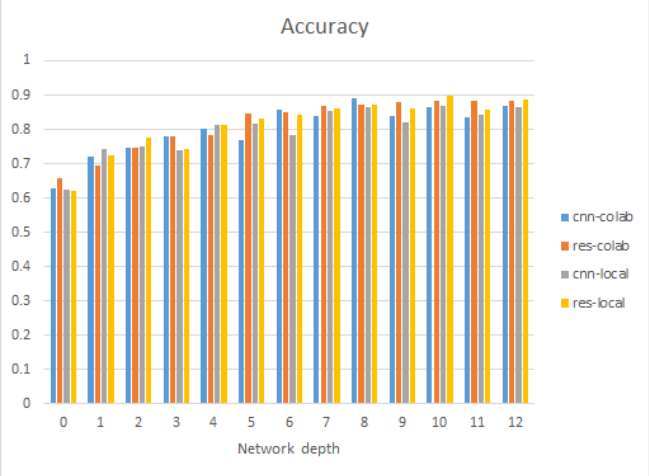

Fig. 10. Values of the accuracy on the testing dataset.

The Fig. 10 shows the achieved accuracy on the testing dataset. The numbers here show the expected correspondence with the loss values shown in the Fig. 7. Again the examples with the depth of 5 and 6 blocks show the unexpectedly low values. The Fig. 10. also clearly shows that for the simple classification tasks with networks of up to 25 layers deep there is no great benefit in using the residual networks. Which agrees with the results in the "Deep Residual Learning for Image Recognition" paper [6]. However better stability is achieved which does have beneficial effects on the stability of the reinforcement learning algorithms.

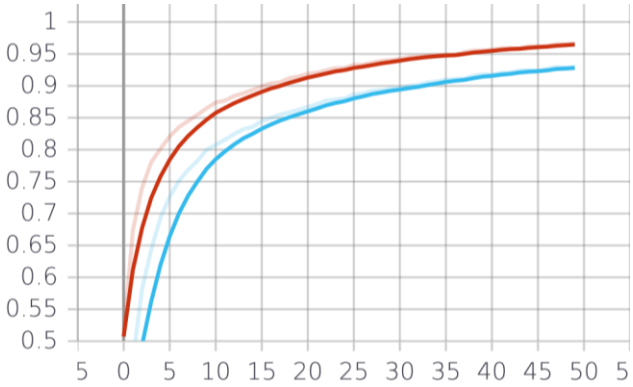

Fig. 11. Values of the accuracy on the training dataset recorded every time step for the convolutional (blue) and residual (red) networks with the depth of 12 residual blocks.

The Fig. 11 and 12 again, expectedly, show faster and more stable convergence to the higher values.

The accuracy metric shown in the Fig. 10, Fig. 11 and Fig. 12 is the categorical accuracy. It is calculated as a simple percentage of accurate classifications averaged across classes. Again, it is the most commonly used metric for the classification tasks when multiple classes exist.

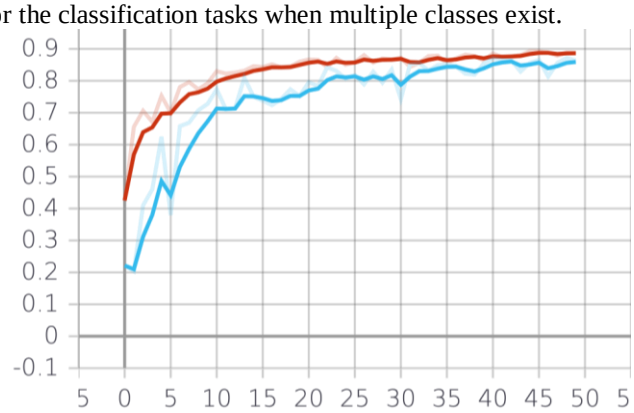

Fig. 12. Values of the accuracy on the validation dataset recorded every time step for the convolutional (blue) and residual (red) networks with the depth of 12 residual blocks.

V. CONCLUSION

It is a matter of time before the reinforcement learning sees more widespread practical use. But for that to happen the algorithms have to mature and become more stable and therefore more predictable, but so do the network architectures. As it was shown in this paper it can be achieved by using the residual neural network instead of the classical convolutional network. This should alleviate some instability form the reinforcement learning process and make it somewhat more stable and repeatable.

Also the majority of the more widely used simulators are currently not designed or very well documented for the use with the reinforcement learning agents. New simulators are being developed particularly for this use and the existing ones are being modified, but currently there is still a lot more work to be done. However, a lot of simple environments, usually in the form of the game console emulators, exist. But those are only usable for the proof of concept benchmarks while designing the algorithms.

ACKNOWLEDGMENT

ROS as a Rapid Prototyping Platform for LIDAR Based Stopping Distance Monitor

Marko Dragojević, Momčilo Krunić, Ninoslav Jovanov and Nemanja Lukić

***Abstract*—Automotive industry is on the rise in last couple of years, and it's most notable goal is producing fully autonomous vehicles. To achieve this goal, complex software systems are introduced. Development of such systems can be very costly, and possible mistakes made in early stages of system design can be hard to amend. That's why different prototyping methods are used to solve potential problems in early stages of development. Different rapid prototyping platforms are used to achieve this. In this paper we will present one prototype solution for obstacle detection application which uses LiDAR to sense vehicle's environment and perform those detections, and also take appropriate actions to warn driver about possible collision. Technologies used for this solution involve, C++ as a language of choice, ROS and Autoware as a framework and GTest/ROStest which are utilized for verification and validation.**

***Index Terms*— Autonomous vehicles; Autoware; ROS; LiDAR; Rapid prototyping; Adaptive AUTOSAR;**

I. Introduction

Autonomous vehicles are slowly but steadily becoming reality. Automotive industry is working towards achieving this goal from day to day. Autonomous vehicles will drastically reduce number of accidents, but also improve quality of life and social welfare in near future. Diverse alliances (such as AAM (Alliance of Automobile Manufactureres) or AUTOSAR Consortium), made of OEMs (Original Equipment Manufacturers), electronics and semiconductors suppliers and technology suppliers, are formed in order to achieve this goal. Autonomous vehicles are exceedingly complex fusions of software systems, electrical systems and mechanical systems. Complexity of software systems begins to grow exponentially with recent introduction of autonomous vehicles. That is why special attention is given to software domain of a modern vehicle. Development of such complex software systems is severely expensive, and mistakes made in early design phases of software systems can prove to be quite difficult to amend. To avoid such mistakes, prototyping takes significant part in automotive software's lifecycle. To make transition from prototype software to actual automotive grade software, different type of prototyping platforms are used. Majority of such platforms are proprietary. Furthermore, different companies have their own prototyping platforms, which makes potential cooperation of different companies complicated. Open source prototyping platforms could potentially solve this problem. One such platform is used as a base for this solution. Autoware [1] is ROS (Robot operating systems) [2] based rapid prototyping platform. It's abundant set of features can be used to produce different kinds of application level software for autonomous vehicles. Furthermore, Autoware platform has interfaces provided to application software similar to those in Adaptive AUTOSAR [3] platform, which presents new platform for Autonomous vehicles and is successor of Classic AUTOSAR platform used in traditional automotive software applications. Despite those similarities, these two platform have their differences where main one is that Autoware is open-source based platform, while Adaptive platform is strictly proprietary and OEM specific, even though platform's specifications are made public by AUTOSAR consortium. Additionally Adaptive platform covers some additional functionalities, which are not present in Autoware, such as execution management and vehicle's diagnostics. In addition to that, underlying implementations may differ severely as Adaptive platform specifies different underlying communicational protocols than ones used in Autoware platform.

Prototype application presented in this paper is used for obstacle detection based on data acquired from LiDAR scans and vehicle stopping distance monitoring based on current vehicle's velocity and distance to detected obstacle.

The rest of this paper is organized as follows: Section 2 describes Autoware platform and related work. Section 3 presents the detail of implemented application. Section 4 describes measurements of applications performances, and comparison to some other similar applications. Section 5 concludes this paper and introduces some possible future works.

II. Related work

Autonomous vehicles as complex systems can be abstracted into sensing, computing and actuation modules. Sensing devices such as LiDARs and cameras allow vehicle to acquire data, which is later used to percept it's environment. Actuation modules handle actual vehicle controls, typically steering wheel and pedals (throttle, break). Computation modules represent the actual "brain" of the vehicle and it

usually involves submodules used for perception of the vehicle's environment, submodules used for planning, and submodules used for decision making based on data acquired from sensing modules. Autoware software model is shown in Figure 1.

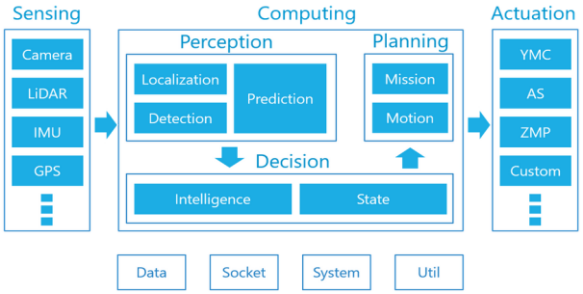

Figure 1. Autoware software stack

Autoware provides this rich set of modules and it can be utilized as an admirable framework for development of autonomous driving applications. Sensors record environmental information, and that information serve as an input to the computing modules. Artificial intelligence plays significant role in perception of vehicle's environment in form of object detection algorithms. Decision portion of the data flow usually takes the form of state machine. And planning portion uses information about detected objects and information acquired form decision making cluster and utilizes it to plan the optimal actions that needs to be executed. More detailed description of Autoware platform can be found in [4].

As already mentioned, Autoware prototyping platform is based on ROS which is a framework for developing robot based applications. ROS is designed to provide means for developing of modular applications in distributed manner. In ROS software is abstracted as nodes and topics. Nodes represent software components that provide some kind of functionality (e.g. Processing LiDAR data to generate 3D map of given environment). Topics, on the other hand serve as a communicational interfaces, which allows nodes to exchange messages. This communicational paradigm is known as Publisher/Subscriber design. When a node publishes message on certain topic, all nodes that are subscribed to that topic get notified about existence of a new message, and the data stored in message becomes available to them. Similar communicational pattern is also used in Adaptive AUTOSAR platform and that is why Autoware, as ROS based platform, could prove to be excellent candidate for prototyping applications, which will later be integrated into Adaptive software stack. ROS also provides rich set of visualization tools such as RViz and data driven simulation tool ROSBAG, which gives user possibility to record and playback ROS traffic on specified topics that was previously recorded. Autoware also utilizes abundant set of well known open-source libraries for different kind of processing. Point Cloud Library (PCL) [5] that is used for processing LiDAR scans and 3D mapping. Beside this, computer vision library for image processing, OpenCV [6] is also used. Furthermore, deep learning frameworks are also utilized e.g. Caffe [7]. Notable part of calculations performed during processing relies heavily on GPU computation frameworks such as CUDA [8] which is developed by NVIDIA.

Utilizing this rich set of software packages provided by Autoware, our prototype application is developed. By using Autoware we ensure certain compatibility of our prototype application with future application as a part of Adaptive AUTOSAR stack. Application should enrich functionality of Autoware platform with additional module that is capable of monitoring vehicle stopping distance based on its velocity and warn or even take an action if there is LiDAR detection in the region of interest. In case of this solution, region of interest represents the lane in front of the vehicle. LiDAR is chosen as a main sensing tool because of it's advantages over cameras, which underperform in extreme conditions, such as situations when weather is poor. To the best of our knowledge, such functionality is not provided in current Autoware stack. This solution could be combined with existing solutions, such as ACC (Adaptive Cruise Control) [9] or FCD (Forward Collision Detection) [10] [11]. Additionally, one existing solution [12] tackles similar problem, which involves pedestrians detection based on inputs from multiple sensors and AEB (Autonomous Emergency Braking) actions. In addition to LiDAR based obstacle detection and emergency brake actions, [13] tackles additional complex problem of time delays which are present in communicational link of teleoperated vehicles. Unlike these solutions, our current solution does not takes those additional actions into account but instead focuses on stopping distance monitoring and providing appropriate warnings. Additionally, outputs from our application could be used as one of the inputs to other systems which can take breaking actions.

III. SOLUTION

In order to provide functionality of stopping distance monitoring, information about vehicle's velocity and LiDAR data acquired from Autoware environment is processed. Top level architecture of solution is shown in Figure 2.

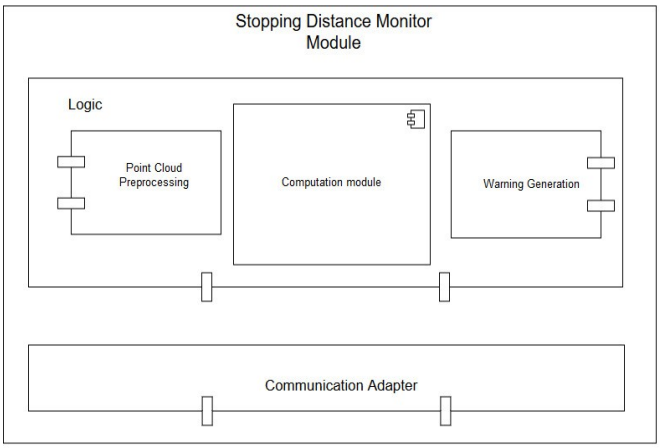

Figure 2. Stopping Distance Module

Proposed solution is organized in several submodules, where each of them provides certain type of functionality. This kind of organization grants us modularity, and loose coupling of our components, which makes it easier to modify each of the submodules, if such action is needed. As this solution is actually a prototype of Adaptive AUTOSAR application, modifications of submodules shall be necessary, when final specification of Adaptive AUTOSAR platform becomes available.

Communication Adapter submodule represents a abstraction of communicational module which allows this application to communicate with its environment. In this case, environment implies to other ROS nodes within Autoware platform, where these nodes provide different kinds of inputs for our application (node), such as point cloud data and vehicle speed estimation. Application can use functionally of Communication Adapter to acquire mentioned data and other relevant information, without actually relying on any of the ROS specific functionalities. In order to use this application in Adaptive AUTOSAR context, only submodule which should be modified is Communication Adapter, with the rest of application unchanged.

After point cloud data is acquired, it's passed to the Point Cloud Preprocessing submodule. Point Cloud Preprocessor will then filter acquired point cloud data, to isolate ROI (Region of interest) and remove other needless detections. Such preprocessing is done by utilizing PCL. By reducing size of point cloud, we relieve computation submodule of additional intense processing. Also, Point Cloud Preprocessor module isolates usage of PCL, so if PCL is not available as a part of Adaptive AUTOSAR platform or different point cloud processing library needs to be used, only this submodule should be modified.

Computation submodule does the work of finding the nearest cluster of points within the preprocessed point cloud, which represents the actual ROI and marks that cluster as a detected obstacle. Organizing detected points in clusters is done with placing each of the detected points into appropriate cells of logical grid, which corresponds to the ROI. After all points from ROI are assigned to the appropriate cell, each cell's point count is checked and if it passes certain threshold, location of that cell is considered as a location of detected obstacle. Furthermore, this submodule keeps track of current vehicle speed, which it acquires from other ROS nodes within Autoware platform, through the Communication Adapter as a medium. Latest received value of vehicle is used to calculate stopping distance in addition to vehicle's maximum deceleration, which is specified as a parameter and distance from the vehicle to the nearest grid cell with point count that surpasses the threshold.

Calculated stopping distance is passed to the Warning Generation submodule, which generates visualization markers which are passed to the ROS visualization tool. Generated markers contain information about free space in front of the vehicle, and the actual length of the stopping distance. If distance to detected obstacle is smaller then calculated stopping distance, warning is generated. Warning Generation submodule utilizes functionality Communication Adapter submodule, to send those generated markers to it's environment. In current prototyping phase of application development, only visualization markers are generated, but in later more matured versions of application as a part of Adaptive stack, this submodule could be modified to generate different types of warnings, or event request adequate actions.

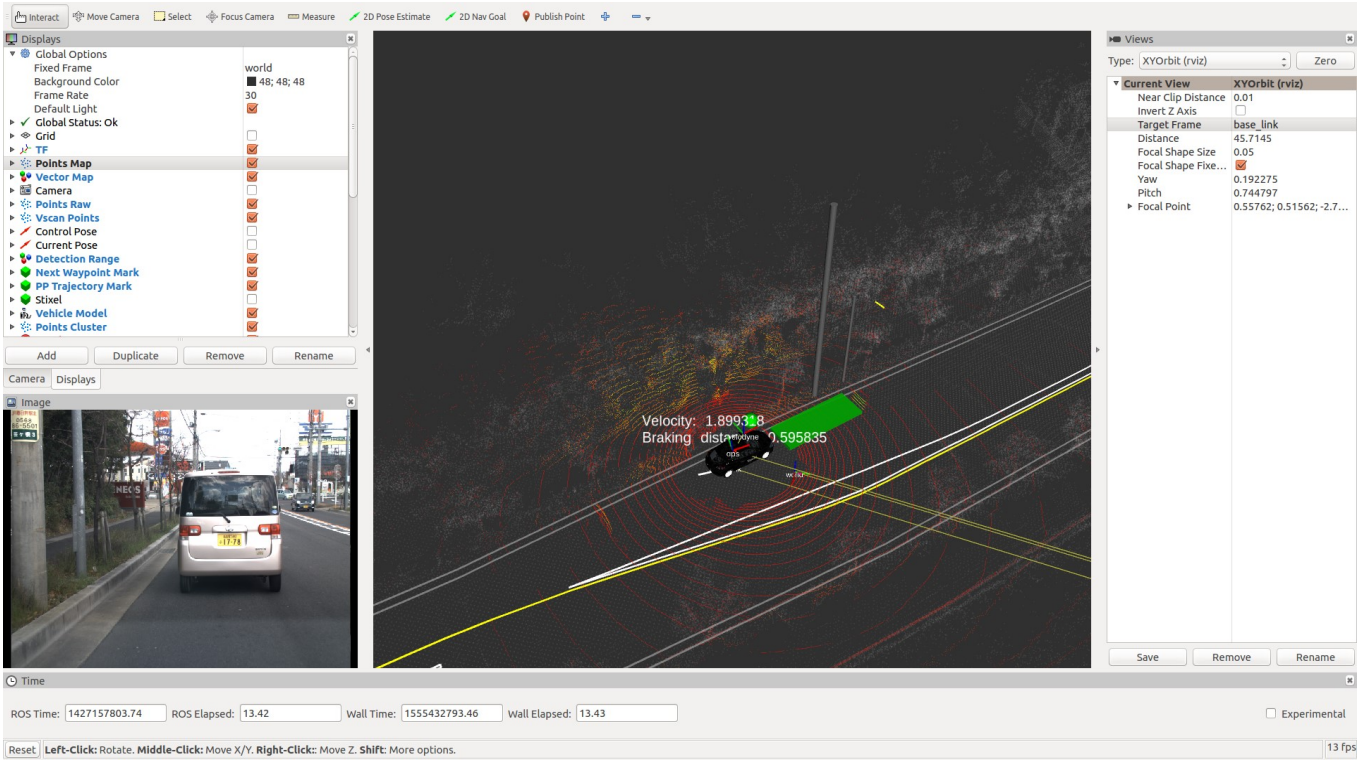

Figure 3. Autoware evaluation environment

IV. EVALUATION

As already previously mentioned, this application is prototype for future application which will be part of Adaptive AUTOSAR stack. Evaluation environment used during prototyping is shown in Figure 3.

Visualization tool RViz was especially useful during development of this solution, because that tool is capable of displaying different types of visualization markers, such as green one in front of the vehicle in Fig. 3 which represents free space in front of the vehicle. In bottom left side of Fig. 3 feed from frontal camera is shown, which gives us an option to visually confirm object detections made by Computing submodule. Data such as internal representation of estimated vehicle's linear velocity, feed from frontal camera or point cloud data is acquired from the set of nodes within Autoware environment. These nodes acquire raw data from ROSBAG file which was recorded during real-life test drive of a test vehicle that had different kinds of sensors attached. These ROSBAG files can later be used to replay acquired sensor data, providing us with valuable simulation scenarios, that gives us opportunity to develop applications similar to one described in this paper.

Described prototype application is developed by utilizing TDD (Test Driven Development) [14] [15] methodology, which grants us with code coverage. Considering this in synergy with CI (Continuous Integration) systems like Jenkins [16] and Autoware's already established support for Docker [17] containerization, we get complete platform that enables us for rapid prototyping, and reduces actual cost of traditionally expensive automotive grade software development. Furthermore, it allows us to focus on providing more complex functionality of software systems rather than focusing on development processes.

Proper functionality of prototype application was verified by means of unit testing. Each of the submodules within application was properly tested, by writing ROStest/GTest test cases which cover different possible scenarios. Beside unit testing, comprehensive testing on integration level was also performed with a goal of ensuring quality of software. Proper integration of our prototype application within the Autoware platform was necessary in order to test its actual functionality. In order to achieve this goal, additional testing ROS nodes were developed to simulate the inputs for our application and to acquire, but also verify its output. With this amount of test cases, we were granted the flexibility of changing functionality of each and everyone of submodules, without concern of accidently breaking down existing functionality. Unit testing results for one of the test cases is provided in Table 1. Execution times displayed in Table 1 represent test cases execution times and do not refer to execution time of application's functionality.

Name	Execution time	Verdict
TestAlphaCalculation	258 ms	Pass
NonEmptyGrid	355 ms	Pass
GenerateROINonEmptyGrid	347 ms	Pass
GenerateROIEmptyGrid	457 ms	Pass
CheckROISizeParam	509 ms	Pass
FindClosestPointValid	253 ms	Pass
FindClosestPointInvalid	305 ms	Pass
CheckClosestPoint	242 ms	Pass
StoppingDistanceCalculation	263 ms	Pass
CalculateVelocityAverage	240 ms	Pass
FilterTestOffset	267 ms	Pass
FilterTestNoOffset	235 ms	Pass
FilterInvalidTestInput	369 ms	Pass
FilterValidTestInput	235 ms	Pass
PointCounting	369 ms	Pass
PublishROIInvalidInput	233 ms	Pass
PublishROIValidInput	371 ms	Pass

Table 1 – Testing results

With that in mind, it is safe to say that we have achieved our goal of establishing a system which would grant us an ability to do rapid prototyping of our application in its early stages of design.

V. CONCLUSION

In this paper, we have shown that open-source prototyping platform, such as Autoware, can be used in rapid prototyping of autonomous vehicles applications. With utilizing Autoware, we were granted a chance of early feasibility check of our application thus reducing chance of inducing flaws in design of our application. Furthermore, new functionality is introduced in form of stopping distance monitoring application based on vehicle's velocity and LiDAR detections, that can warn driver or even, in later stages of development, take appropriate action in form of braking.

As this application prototype was developed by considering some of the applicable requirements defined in ISO26262 [18] standard such as providing full vertical and horizontal traceability, providing specification for software architecture and also integration and testing strategy, final Adaptive application could be more easily adapted to satisfy safety standard to given extent.

Never-Ending Ontology Learning Approach Applied to Biomolecular Function Prediction

Nenad Petrović and Milorad Tošić

***Abstract*— Biomolecular function prediction is an important task in biomedical sciences. However, most of the existing solutions for automated function prediction are based on structural sequence similarity methods that do not always give satisfying results, as structural similarity does not necessarily lead to functional similarity. In this paper, we propose a semantic approach for biomolecular function prediction based on never-ending learning paradigm applied to ontology learning and knowledge extraction. PubMed biomedical literature repository is used for this purpose with objective to refine the results returned by BLAST that is performing the calculation of similarity using local sequence alignment. For the refinement of results, the molecule similarity on semantic level is also considered. The implementation of ontology learning and knowledge extraction modules is presented, while the prediction-related module is still a prototype in progress.**

***Index Terms*—bioinformatics; ontology learning; text mining.**

I. Introduction

Every day, organizations all over the world generate enormous amount of data in textual format about various topics – including emails, articles, books to reports and experiment results. Nowadays, the storage capacity of computers is more than enough to enable storage of all the content without deleting anything. However, one of associated challenges is ability to manage the stored information considering mutual relations [1], as it does not only ease the information retrieval but also provides ability to generate new knowledge using reasoning and inference mechanisms. A possible approach to organize information in such way in computer science is to use ontologies.

Ontologies are formal and explicit specifications in form of concepts and relations of shared conceptualizations within a particular domain of interest [2]. They are used as metadata schemas, providing a controlled vocabulary of concepts, each with explicitly defined and machine-processable semantics [3]. In this sense, they govern the way the corresponding knowledge bases are populated [4]. However, the creation of ontologies requires additional efforts leading to an initiative to automatize the process of ontology creation. Ontology learning is the process of deriving high-level concepts and relations from information in order to construct an ontology in automatic or semi-automatic way [1, 4].

Amount of available biomedical literature, texts and experimental data is increasing at exponential rate. The same applies to the number of biomolecules (proteins and genes) being identified and their structure determined, due to advances in high-throughput sequencing techniques [5]. Furthermore, it is needed to extract useful knowledge instead of simple information from these large data volumes in order to answer critical question, such as what do all these newly discovered biomolecules do. However, it is impossible to keep up with the data volume growth rate by only performing the manual annotation of discovered molecules. For that reason, the scientists have been turning to sophisticated computational methods when it comes to annotation of huge volume of molecular sequence and structure data [5]. Most of the current molecule function prediction systems are based on sequence similarity approach (homologous transfer). Despite the fact that it seems intuitive, this approach might not be always the right choice, as structural similarity does not always lead to functional similarity [5,6,7]. Moreover, the structure of biomolecules inside cell is far from static and many functions are associated with the cellular environment. Therefore, combination of heterogeneous data about molecules (publications, experimental results) has become a promising direction for function prediction [6,7].

In this paper, we propose a semantic approach to biomolecular function prediction based on never-ending learning paradigm applied to ontology learning and knowledge extraction. For this purpose, PubMed[1] biomedical literature repository is used. The main goal is to refine the results returned by BLAST[2] that is performing the calculation of similarity using local sequence alignment. For the refinement of results, similarity of the molecules at semantic level is considered. A proof-of-concept prototype is presented to illustrate the system capabilities.

One of the solutions that are using heterogeneous sources to enhance biomolecule function prediction [6] combines information from structure and sequence homologies with protein–protein interaction networks for improved protein function predictions. Moreover, the Extended Similarity Group (ESG) [8] for protein annotation prediction iteratively searches the homology space around the queried protein and draws conclusion about protein function based on annotations of similarly annotated proteins using gene ontology. In contrast to solution presented in [8] that relies on pre-defined Gene Ontology[3] annotations, approach proposed in this paper builds upon framework for automated ontology learning and knowledge extraction, with more flexibility and possibility to improve the prediction in time by analyzing new biomedical publications on a daily basis by adoption of the never-ending learning approach.

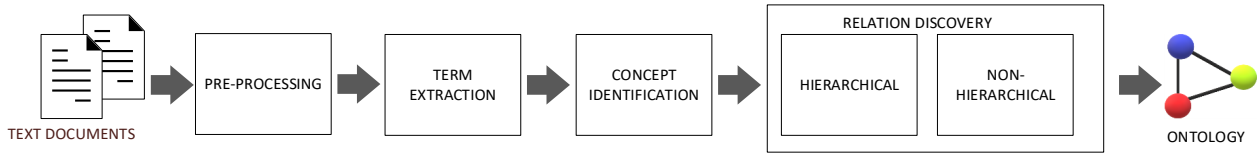

Fig. 1. Ontology learning process

II. Background and Related Work

In this section, the work that our research is build upon is presented and described how it contributes the overall solution.

A. Ontology learning

Ontology learning is a research area focused on automated discovery and construction of ontologies using corpus of textual sources [1]. Ontology learning process consists of identifying terms, concepts and relations between them within the text, in order to construct an ontology [1,4]. The process is illustrated in Fig. 1.

First, the documents need to be pre-processed in order to make sure they are in the right format, so they can be further used within the ontology learning system. After that, the term extraction is performed. Term extraction is a part of ontology learning process whose objective is to obtain terms that could be considered as linguistic realizations of everything important and relevant to the domain [1,4]. Concept is a set of one or many terms which denote an abstract idea or mental picture of a group or class or objects [1]. However, not all the detected terms are suitable to be chosen as concepts. We consider that a corpus of documents on the specific topic consists several knowledge abstractions that are regularly found several times within the text. Therefore, it is needed to identify these terms for the particular topic. Furthermore, it is needed to find the relations between the concepts that describe some kind of bond between them. There are two types of relations: taxonomic (hierarchical) and non-taxonomic (non-hierarchical) [1,4]. The main task related to taxonomic relations is to construct hierarchies by discovering *is-a* relations (hypernym/hyponym) between the concepts [1,4]. Non-taxonomic relations are other interactions between the domain concepts, such as meronymy (*part-of*), possession (*has-a*), roles, attributes and causality [4]. In general, the discovery of non-taxonomic relations relies on the analysis of syntactic structure and dependencies. Verbs are often good candidates when it comes to identification of non-taxonomic relations [4].

In context of this paper, the ontology learning process is considered for construction of ontology schemas for the knowledge base about proteins based on public repository of biomedical literature PubMed with purpose of providing means for prediction of gene functions based on semantic technology. Furthermore, a variation of ontology learning is used in order to populate the semantic triple store by extracting the knowledge from the text documents about given topic.

B. tf-idf

As it was mentioned previously, it is important to find the terms that are most relevant to the specific topic, as they could be candidates for important domain concepts. For this purpose, we decide to use the tf-idf technique.

Term frequency- inverse document frequency (tf-idf) is a numerical statistic often used in information retrieval and text mining to determine the importance of word within to a document within the collection or corpus [9]. The value of tf–idf increases proportionally to the number of times that the observed word appears in the document and is offset by the number of documents in the corpus that contain the word, which makes up for the fact that some words appear more frequently in general. Typically, the tf-idf consists of two factors: term frequency (tf) and inverse document frequency (idf).

Term frequency is the number of times a word appears in a document, divided by the total number of words in that document:

$$tf(t) = \frac{\text{Number of times term t appears in a document}}{\text{Total number of terms in the document}}$$

Inverse document frequency (idf) is computed as the logarithm of the number of the documents in the corpus divided by the number of documents where the specific term appears:

$$idf(t) = ln\frac{\text{Total number of documents}}{\text{Number of documents with term t in it}}$$

C. Ontology alignment

Alignment represents correspondence between entities of two ontologies [10]. It is produced by ontology matcher using ontologies as input.

There is a distinction between two types of matching: schema-based and instance-based [11]. A schema-based matcher takes various aspects of the concepts and relations within the ontologies and uses some similarity measure to determine correspondences. Instance-based matcher takes the instances that belong to the concepts in the ontologies and compares them to discover similarity. On the other side, there is also a distinction between element-level and structure-level matching [11]. While element-level matcher compares properties of the particular concept or relation, a structure-level matcher compares the structure of the ontologies to find similarities. However, these matchers can also be combined.

In scope of this paper, we use instance-level, property-based ontology similarity matcher to find the molecules that have similar semantic descriptions obtained from document corpus during the instance-level ontology extraction. Similarity on semantic level is taken into account as indicator of potential molecule function similarity in combination with molecule-level sequence homology. Moreover, schema-level ontology alignment is used for evaluation of the created ontologies. For implementation, we use Alignment API[4] presented in [10].

[4] http://alignapi.gforge.inria.fr/

D. Never-ending learning

Never-ending language learner is an intelligent computer agent that runs continuously with purpose of reading information from the web in order to populate its knowledge base, while it learns to perform this task better every day [12, 13]. Most machine learning systems learn to perform some function based on statistical analysis of a single data set. On the other side, never-ending learning paradigm is inspired by the fact that humans learn many different functions and obtain various types of knowledge over years of accumulated diverse experiences, using extensive background knowledge learned from previous experiences to guide subsequent learning [12, 13].

A never-ending learning problem is defined as £=(L, C) [4]. L is an ordered pair that consists of a set $L = \{L_i\}$ of learning tasks, where the i^{th} learning task $L_i = (T_i, P_i, E_i)$ is to improve the agent's performance, as measured by performance metric P_i, on a given performance task T_i, through a given type of experience E_i. Furthermore, it includes a set of coupling constraints $C = \{(\varphi_k, V_k)\}$ among the solutions to these learning tasks, where φ_k is a real-valued function over two or more learning tasks that specifies the degree of satisfaction of the constraint, and V_k is a vector of indices over learning tasks, specifying the arguments to φ_k. Each performance task is a pair $T_i \equiv (X_i, Y_i)$ defining the domain and range of a function which has to be learned $f_i^* : X_i \rightarrow Y_i$. The performance metric $P_i : f \rightarrow R$ defines the optimal learned function for the i^{th} learning task defined as $f_i^* \equiv argmax_{i \in Fi} P_i(f)$, where F_i is the set of all possible functions from X_i to Y_i. As time passes, the goal is to increase the quality of learned functions (as measured by the individual performance metrics $P_1 \ldots P_n$) and the degree to which the coupling constraints C are satisfied.

In our system, never-ending learning approach is being adopted for both the ontology learning process and biomolecule function prediction. In the first case, an ontology evaluation metric is used as a performance metric, while in the second case prediction success rate is considered for that purpose. Therefore, as time passes, it is expected that system is able to collect more knowledge that enables to perform better prediction by extracting knowledge from larger number of documents describing the biomolecule structure and features. The imposed constraints are related to the number of texts taken as input. First, the theoretical texts about biomolecules are analyzed to build domain ontologies. After that, the information from biomedical literature is extracted and knowledge base populated. Once the system extracts knowledge from a given number of publications and experimental results, it is possible to perform prediction. The prediction performance is measured every day and system continuously explores more and more texts every day in order to extend its knowledge about both the ontology schema and concrete instances that could improve the quality of prediction. The whole process is illustrated in Fig. 2.

E. Sequence homology and homology-based transfer

Sequence alignment is a method of arranging the sequences of DNA, RNA, or protein in order to identify regions of similarity that may be a consequence of functional, structural, or evolutionary relationships between the sequences.

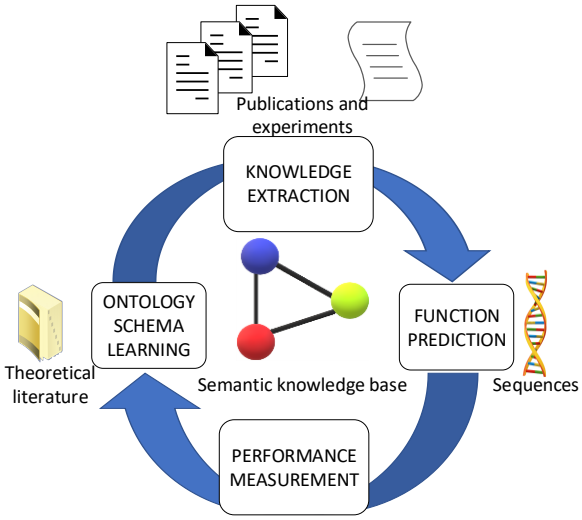

Fig. 2. Applying the never-ending learning approach to biomolecule function prediction

The discovery of sequence homology to a known molecule provides the first ideas about the function of one that has just been discovered [14]. This the most common method of computational function prediction, known as homology-based transfer. The biological rationale behind the homology-based transfer is that if there are two sequences with high degree of similarity, then it is assumed that they have possibly evolved from a common ancestor, so they could have similar functions [5].

Sequence similarity measures can be either global or local. Global similarity algorithms attempt to align every residue in each sequence with purpose of performing the overall alignment of two sequences. This method is most useful when the sequences involved are similar and of roughly equal size. On the other side, local similarity measures seek relatively conserved subsequences, and a single comparison may return several distinct subsequence alignments. Local similarity measures are generally preferred for database search, as cDNAs could be compared with partially sequenced genes and more useful in case of dissimilar sequences that are suspected to contain regions of similarity or similar segments within the wider context.

Basic Local Alignment Search Tool (BLAST) [14] is one of the most commonly used software platforms for sequence similarity which can be used either via web interface or as a stand-alone tool to compare the user's provided sequence against the database of known sequences. There are several types of BLAST to compare all combinations of nucleotide or protein queries with nucleotide or protein databases. BLAST performs comparisons between pairs of sequences, looking for regions of local similarity. The output of BLAST is a list of molecules ordered by descending similarity score between the queried sequence and those that were found similar within the sequence database. However, the sequence that is most similar to the query is not necessarily the one that is identical in function.

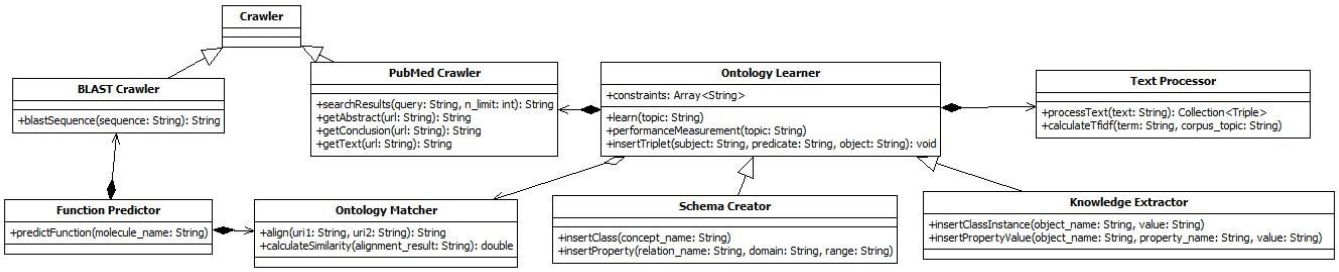

Fig. 4. UML class diagram of the system prototype

Within the scope of this paper, homology-based transfer is considered as an auxiliary factor for function prediction of newly discovered sequence, but not the only one, as our approach is also involving techniques related to semantic similarity of sequences, based on the instance-level ontology matching.

III. Architecture and Implementation Overview

In this section, the architecture overview of the implemented system is given (illustrated in Fig. 3.).

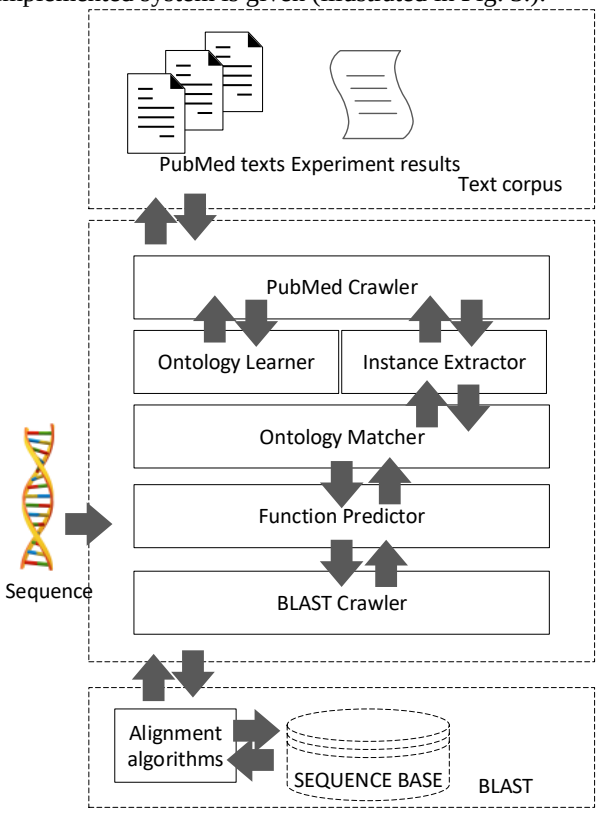

Fig. 3. Gene function prediction system based on never-ending ontology learning approach

The implemented prototype is a Java application with REST API, accessed via web browser. There are three main processes in our system: ontology learning, knowledge extraction and gene function prediction.

First, the ontology learning is performed. Various textual inputs can be used for this purpose (scientific texts, experiment results etc,). In our implementation, the PubMed crawler extracts abstracts and contents of text documents on a given topic in order to construct corresponding ontology schemas according to the algorithm given in Listing 1.

When it comes to text processing, the triplets in form *(subject, predicate, object)* are extracted from each text. For this purpose, we use Stanford CoreNLP Natural Language Processing Toolkit [15], that transforms the given text into a collection of triplets.

Input: topic name
Output: ontology
Steps:
1. Retrieve top n documents from PubMed about the given topic;
2. for each of the retrieved documents
3. get triplets from text;
4. calculate tf-idf of terms;
5. end for each
6. find most relevant concepts about the topic based on tf-idf of terms
7. for each noun
8. insert class(noun);
9. end for each
10. for each verb
11. if(is-a) then
12. insertProperty(subject, is subclass of, object)
13. else
14. insertProperty(domain, verb, range);
15. end if;
16. end for each
17. end

Listing. 1. Pseudo-code of the ontology learning algorithm

Moreover, the most relevant nouns are extracted according to tf-idf and they become classes within the ontology schema. After that, the properties are identified. The most important verbs become properties – either describing taxonomy or other types of relations between the discovered classes.

Once the ontologies are constructed, the knowledge extraction is performed. In this process, the knowledge base is populated by triplets that are instances of the previously constructed ontologies for various molecules. This can phase can be described as instance-level ontology learning and the algorithm is quite similar to one presented in Listing 1., starting from line 7, with additional steps of class and relation matching with the existing schema. The processes of ontology learning and knowledge extraction are alternating according to the never-ending learning approach. The more time passes, the more knowledge is held by the system, so it is expected to perform much better predictions based on this knowledge.

Finally, it is possible to perform the prediction of gene function based on its sequence and knowledge extracted from PubMed literature, according to the algorithm given in Listing 2.

In what follows, the gene function prediction algorithm is described. The pre-condition is that the knowledge about the given molecule is extracted (if there is literature on the topic). After that, the BLAST crawler queries the sequence database with a given input sequence. As output, all the sequence homologs are returned. Among them, there are potential candidates whose functions might be similar to the molecule that contains the queried sequence. This is where the ontology learning and knowledge extraction plays role. Furthermore, the instance-level ontology alignment of the

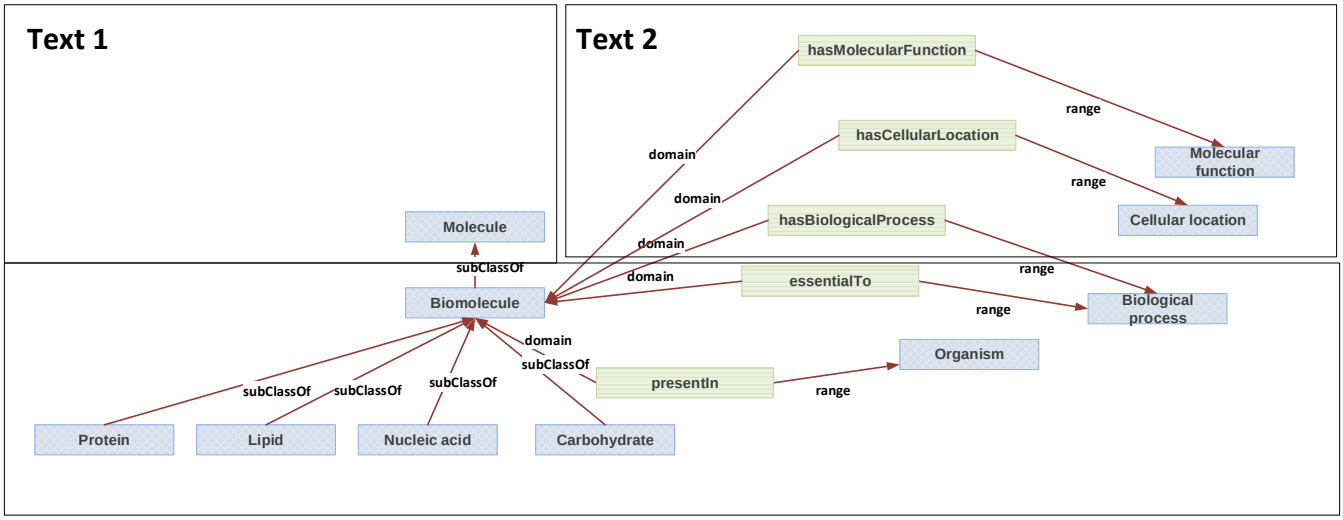

Fig. 5. Ontology schema learning example

knowledge about the input molecule is performed against the knowledge of the homologs. The one that is semantically most similar is the one whose function is transferred to the new sequence. In Fig. 4, a detailed UML class diagram of the implemented system prototype is given.

Input: molecule name, molecule sequence
Output: function prediction
Steps:
1. extract semantic knowledge about molecule from texts
2. candidates=blast(molecule sequence, top-n)
3. max=0;
4. for each candidate
5. similarity=ontologyAlign(candidate, molecule name) ;
6. If(similarity>max) then
7. max=similarity;
8. end if;
9. end for
10. retrieve functions of candidate molecule with max similarity to input molecule
11. return functions prediction;

Listing 2. Pseudo-code of gene function prediction algorithm

As it can be seen in Fig. 4, two central classes within the system are *Ontology Learner* and *Function Predictor*. *Ontology Learner* is further split into two classes: *Schema Creator*, that is responsible for insertion of classes and properties into the ontology schema and *Knowledge Extractor* whose role is to populate the triple store with the knowledge about the particular topic (property values and detected relations between relevant classes) following the structure of previously constructed schema. Both of them contain *Text Processor* and *PubMed Crawler* objects. *Text Processor* is based on Stanford CoreNLP and transforms the text into a collection of triplets. Moreover, it is able to calculate tf-idf of each term within the document corpus. *PubMed Crawler* is able to get the n most relevant texts about the given topics and extract their abstracts and contents. These texts are used for both ontology learning and knowledge extraction. It uses *Ontology matcher* for alignment performance measures according to the pre-defined set of constraints for different knowledge base sizes and number of documents processed within the corpus. On the other side, *Function Predictor* contains *Ontology Matcher* that aligns two ontology instances and is able to return the numeric value assigned to the achieved alignment. Moreover, *Function Predictor* contains *BLAST Crawler* that is responsible for molecule segment alignments used for creation of the initial set of candidate molecules for gene function prediction. The final output of the system is a string that holds the list of predicted functions for a given sequence.

IV. Ontology Learning and Knowledge Extraction Scenario

In this section, we present a simple scenario illustrating how the implemented prototype works when it comes to ontology learning and knowledge extraction. Let us assume that we have two text from theoretical biomedical literature that are analyzed about biomolecules.

The first one is taken from Wikipedia:

„Biomolecule is a molecule that is present in organisms, essential to some typically biological process. Biomolecules include large macromolecules such as proteins, carbohydrates, lipids, and nucleic acids.“[5]

And, the second is an excerpt from [5]:

„There are three important functional aspects of biomolecules: molecular function, biological process and cellular location“.

Once these two texts pass through our system, the ontology about biomolecules is being built, as shown in Fig. 5. As it can be seen, the information from both texts is taken into account to form the ontology schema. However, redundant relations and concepts might appear, such as *hasBiologicalProcess* and *essentialTo* that both express the same relation between biomolecule and biological process. Therefore, it is needed to eliminate duplicate concepts and relations.

Let us consider the following text about protein kinase: *“Protein kinase is found in human, animals, bacteria and plants. Kinase has molecular function to modify other proteins. It is involved in biological process of cellular pathway regulation”.*

After text analysis, the knowledge base is populated according to the ontology schema, as illustrated in Listing 3.

Listing 3. Protein kinase knowledge base population example

For evaluation of the achieved results, a gold standard-based approach was used [16]. The learned ontologies were compared with a previously created reference ontologies referred to as gold standard. After that, the ontology alignment was performed between the learned ontology and gold standard. According to the results, the average matching for ten ontologies about biomolecules created using texts from Wikipedia and PubMed was around 78%. It was noticed that the ontology learning system struggled with texts containing complex language constructions with many ambiguities.

V. Conclusion and Future Work

In this paper, we have proposed an architecture of a system for biomolecule function prediction based on publicly available biomedical literature and experiment results adopting the never-ending ontology learning and knowledge extraction approach. As a proof-of-concept, we have implemented a prototype in Java programming language.

According to the initial testing, the approach gives satisfactory results when it comes to ontology learning and also seems promising for refinement of BLAST similarity score results in combination with knowledge extracted from PubMed text summaries. However, as this is still a work in progress, we plan to further improve the ontology learning system and perform accurate evaluation of molecule function prediction performance in near future. Furthermore, we would like to experiment with various similarity techniques based on expert knowledge from biomedical domain in order to determine which kind of alignment on semantic level leads to better prediction results. It could be also beneficial to include various text sources from the web (beside PubMed) to construct more complete knowledge base. Moreover, we would like to adopt the similar approach to respond other challenges in biomedical sciences, such as diagnosis and predictive medicine [17]. Finally, the idea is to extend the proposed approach to sensor data and integrate it with our framework for ontology-based coordination of autonomous robots [18].

Upravljanje redundantnom robotskom rukom s višestrukim pogonima i pokretanjem sajlama

Aleksandar Rodić, Miloš Jovanović i Ilija Stevanović

***Sadržaj*—U radu se razmatraju aspekti projektovanja inteligentnog upravljanja redundantnom robotskom rukom pokretanom sajlama s višestrukim servo-pogonima. Na početku, biće prikazana konstrukcija robotske ruke redundantne kinematske strukture s 7 stepeni slobode kretanja, čiji je prototip mehanizma u fazi pripremem za izradu. Takođe, biće dat matematički model višestruko aktuirane robotske ruke na bazi kojeg je urađena simulacija sistema i sprovedena inkrementalna poboljšanja mehaničke strukture u fazi razvoja prototipa robotskog mehanizma. U radu se sintetizuje fuzzy kontroler robotske ruke, na višem hijerarhijskom nivou, s zadatkom upravljanja višestrukim pogonima I pokretanjem mehanizma posredstvom sajli. Verifikacja performansi sintetizovanog inteligentnog kontrolera urađena je korišćenjem simulacionih eksperimenta. Rezultati će biti analizirani i prikazani u poslednjem odeljku rada. Budući pravci istraživanja i razvoja biće istaknuti na kraju rada kao i neki aspekti primene redundantne robotske ruke s višestrukim pogonom.**

***Index Terms*—Laka robotska ruka, višestruki pogoni, redundantni mehanizam, pokretanje sajlama, inteligentno upravljanje**

I. UVOD

Rad se bavi problemima inteligentnog upravljanja višestruko aktuiranog robotskog mehanizma veličine ljudske ruke, s pogonom uz pomoć sajli i višestrukim pogonima. Cilj istraživanja i razvoja u ovom radu je postizanje performansi robotske ruke koje se mogu porediti s manipulativnim sposobnostima i veštinama ljudske ruke kao biološkog organa. Čovekova ruka sastoji se od skeletnog sistema koji joj daje neophodnu čvrstinu, mišića koji ostvaruju kretanje, nervnog sistema koji omogućava osetljivost na spoljašnje pobude i sistema krvotoka koji obezbeđuje ishranu tkiva i dovođenje energije do mišićnih vlakana. Anatomski posmatrano, ruka s šakom se pokreće uz pomoć više od 40 mišića raspoređenih u ramenom pojasu, nadlaktici, podlaktici i u samoj šaci. Njihovom sadejstvom, ostvaruje se veliki broj raznovrsnih kretanja. Velika redundansa u broju mišićnih vlakana podrazumeva da pojedini stepeni slobode kretanja budu ostvareni sadejstvom 3-4 nezavisna mišića. Na taj način, mišići ruke superponiraju svoje mišićne tonuse tako da generišu pokrete ruke. Takođe, u slučaju povrede ili pucanja mišićnog vlakna, ruka ne ostaje nepokretna već nastavlja da obavlja svoje funkcije u oslabljenom kapacitetu. Može se reći da je priroda za vreme evolutivnog razvoja ljudskih bića stvorila vrlo suptilan anatomski sistem koji minimizuje rizike od potpunog gubitka funkcionalnosti upravo korišćenjem bioloških redundansi u sistemu. U ovom radu, cilj nam je bio da sintetizujemo jedan inteligentni robotski kontroler robotske ruke koji će urediti aktivnosti redundantnog pogona mehanizma ruke u cilju postizanja boljih dinamičkih performansi mehanizma u poređenju s konvencionalnim robotskim pogonima tipa "jedan zglob – jedan servo-motor".

Kod konvencionalnih robotskih mehanizama, u slučaju oštećenja i/ili otkaza jednog od aktuatora, robot trajno gubi sposobnost kretanja u tom pravcu (oko partikularne ose). Po našem mišljenju, redundantnost strukture i višestrukost pogona značano mogu unaprediti performanse sistema ali zato otežavaju (komplikuju) njegovo upravljanje.

Prosečna težina ruke odraslog čoveka je 4-5 kg i zavisi od konstitucije i pola osobe. Istovremeno, ljudska ruka u opštem slučaju, može podići teret od 3-4 kg u odručenom položaju. U proseku, čovek taj teret može držati rukom u odručenom položaju ne više od jednog minuta. Nakon toga, ljudski mišići se zamare, ulaze u zasićenje i moraju se relaksirati da bi povratili svoju funkciju. U robotici, sposobnost da robot podigne teret, lakši ili teži od svoje sopstvene težine, se izražava jedinstvenim indeksom koji se naziva "maseni odnos" (engl. mass-payload ratio). Ovaj indikator predstavlja fizički odnos mase robota i maksimalnog tereta kojeg robot može da podigne bez preopterećenja ili oštećenja strukture. Kod ljudi, ovaj indeks je približno jednak jedinici. Ljudska ruka može kratkotrajno podići teret koji je teži od sopstvene težine. Nasuprot, industrijski roboti imaju značajno veću vrednost pomenutog masenog indeksa od jedinice. Razlog za to je strog zahtev da se robotska struktura industrijskih robota učini što robusnijom i krućom. Kada govorimo o preciznosti ljudske ruke, ona iznosi ne više od 1-1,5 mm. Ljudska šaka ima ulogu da obezbedi veću tačnost (recimo manju od 0,2 mm) dok je zadatak ruke (do zgloba šake) da obezbedi tzv. prenosno kretanje i da dovede šaku u određenu poziciju [1].

II. STANJE U OBLASTI

Poslednjih godina bilo je uspešnih pokušaja da se razviju različite lake robotske ruke [2]-[8]. Mnogi od njih, implementirali su način za pokretanje zglobova potezanjem sajli, po uzoru na pokretanje ruku tetivama. Glavne poteškoće kod ovih sistema pokretanim sajlama odnose se na elastičnosti sistema i unutrašnja trenja a to dovodi do problema s preciznošću i ponovljivošću robota. Drugi problem odnosi se na mehaničku robusnost robotske ruke. Jedna od interesantnih

Aleksandar Rodić iz Instituta "Mihajlo Pupin" Beograd, Centar za robotiku, Volgina 15, 11060 Beograd, Republika Srbija (e-mail: aleksandar.rodic@pupin.rs).

Miloš Jovanović iz Instituta "Mihajlo Pupin" Beograd, Centar za robotiku, Volgina 15, 11060 Beograd, Republika Srbija (e-mail: milos.jovanovic@pupin.rs).

Ilija Stevanović iz Instituta "Mihajlo Pupin" Beograd, Centar za robotiku, Volgina 15, 11060 Beograd, Republika Srbija (e-mail: ilija.stevanovic@pupin.rs).

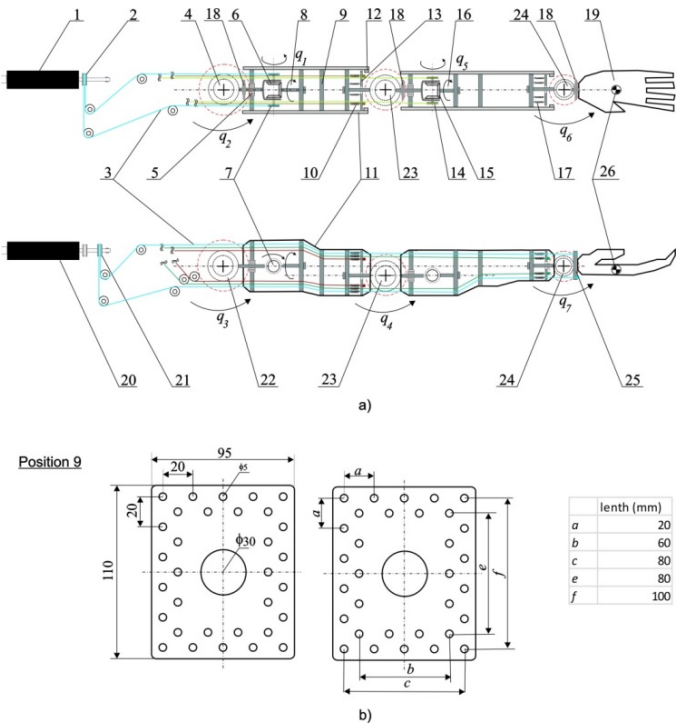
konstrukcija u zadnje vreme je AMBIDEX robotska ruka [2] koja je nastala kao rezultat istraživanja i razvoja uzajamne saradnje i koegzistencije biološko-tehnološkog para čovek-robot. Robotska ruka AMBIDEX koristi inovativno rešenje pogona uz pomoć sajli koje čini interakciju s čovekom bezbednijom nego obično. Sa samo 2,6 kg, ova ruka teži manje od prosečne ljudske ruke muške, odrasle osobe. AMBIDEX može razviti maksimalnu brzinu od 5 m/s i može podići do 3 kg tereta. Zato što se AMBIDEX robotska ruka može upravljati na istovetan način kao industrijski robot, ona može imati veliki broj primena, od jednostavog podizanja tereta pa do izvođenja složenih zadataka koji zahtevaju preciznu manipulaciju i kooperaciju s drugim subjektima. AMBIDEX podržava velike brzine, bežičnu komunikaciju, upravljanje u realnom vremenu s daljine korišćenjem malog kašnjenja i velikog protoka 5G mreže. Inovativno rešenje, koje će biti predstavljeno u ovom radu, uprošćava mehaničku strukturu robotske ruke, povećava robusnost sistema zadržavajući u isto vreme preciznost i ponovljivost sličnu biološkom modelu.

III. KONSTRUKCIJA

Robotska ruka je tako konstruisana da ispuni zadate tehničke zahteve koji su komentarisani u Odeljku-I ovog rada. Aktuatori robotske ruke su izmešteni iz zglobova u njegovu bazu da bi se smanjila težina mehanizma. Uobičajeno, masa servo-motora, odgovarajućih reduktora i kućišta (mehaničkog rama) predstavljaju najteže elemente robotske ruke. Ako pretpostavimo da robotska ruka predstavlja deo jednog dvoručnog robotskog sistema, onda je pogodno da servo-motori budu smešteni u osnovi sistema. U specijalnom slučaju, robotsku osnovu čini torzo (trup) dvoručnog robota. Pokretanje robotske ruke, u poređenju s konvencionalnim industrijskim robotima gde su servo-motori smešteni u zglobovima mehanizma, izvodi se sinhronizovanim povlačenjem i otpuštanjem žica (sajli) napravljenih od nerastegljivog materijala (čelična žica, Kevlar i sl.). Pogonske sajle su jednim krajem prebačene (vezane) preko motorizovanih koturača, postavljenih na izlazna vratila reduktora pogonskih motora, dok su svojim drugim krajem vezane za mesta na robotskim segmentima, kao što je prikazano na Sl. 1a.

U biološkom svetu, tetive kao nastavci mišića su povezani u odgovarajućim tačkama za kosti ruke. Segmenti robotske ruke, da bi bili što lakši i istovremeno imali odgovarajuću mehaničku čvrstoću, su izrađeni od Al-ploča (poput sendviča) s dodatnim ramom između ploča (Sl. 1a i 2) koji dodatno ukrućuje strukturu. Unutrašnjost segmenta se koristi za prolaz poteznih sajlica, električnih provodnika i vodova senzorskih signala. U unutrašnjosti segmenta robotske ruke (Sl. 1a, detalj 11) postavljene su i fiksirane za zid, odgovarajuće sprovodne ploče (Sl. 1, detalj 9). Sprovodne ploče (nalik na „kapije“) imaju male otvore raspoređene po obimu u dve paralelene vrste na rastojanju 20mm jedni od drugih (Sl. 1b). Male rupice, u sprovodnim pločama pokretačkih sajli, dozvoljavaju provlačenje uskih silikonskih cevčica kroz koje su provučene nerastegljive sajlice (poput ručnih kočnica kod bicikla).

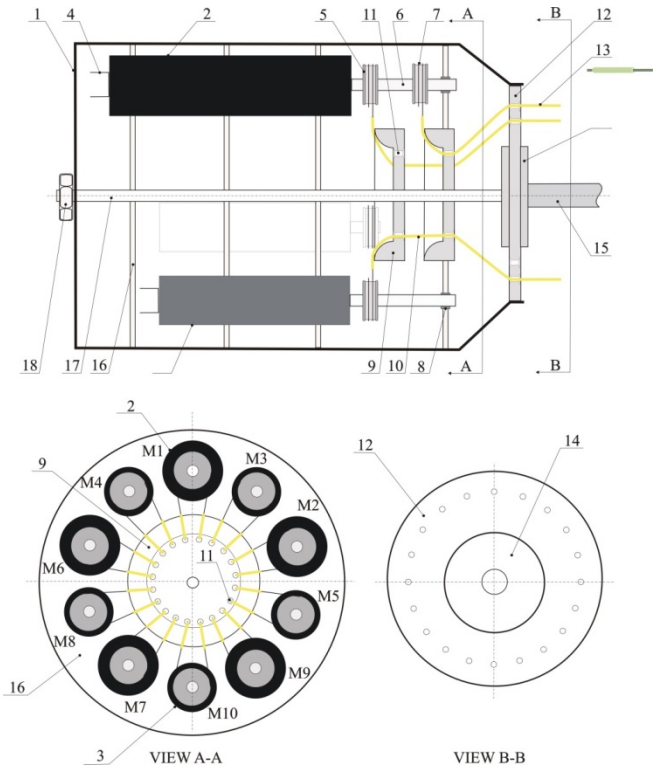
Višestruko aktuirani zglobovi robotske ruke konstruisani su kao sverni (rotacija oko 3 ose) ili dupli cilindrični zglobovi (Sl. 2, detalji 2 i 3). Zglobovi su konstruisani kao kardanski zglobovi kao što je ilustrovano na Sl. 2. Robotska ruka ima redundantnu kinematsku strukturu s 7 mehaničkih stepeni slobode kretanja. Ose zglobova 22 i 23 (Sl. 1a) se ne poklapaju i međusobno su pomerene za 20 mm jedna u odnosu na drugu. Ose zglobova 22 i 24 su kolinerane (Sl. 1a). Nepodudarnost osa zglobova (ramena i lakta) obezbeđuje smanjenje opterećenja pogonskih servo-motora koji pokreću zglob lakta. Sinhronizovanim povlačenjem i otpuštanjem nerastegljivih sajli, od strane servo-motora posatvljenih u bazi robota, generišu kretanje robotske ruke u zglobovima ramena, lakta i zgloba šake (Sl. 1a). Mehanička snaga servo-motora, uz pomoć motorizovanih doboša, se prenosi na sajle i dalje do tačaka vezivanja na segmentima robota. Pronacija i supinacija nadlaktice se ostvaruje pomoću koničnog zupčastog para. Linearno kretanje poteznih sajlica se pretvara u obrtno kretanje koničnog zupčastog para smeštenog neposredno iza ramenog zgloba (Sl. 1). Pogonski servo-motori mehanizma robota su smešteni u bazi robota kao što je prikazano na Sl. 2. DC-motori s planetranim reduktorima su poređani u krug i montirani su u cilindrično kućište kako bi zauzeli što manje prostora. Motorizovani doboši su postavljeni na izlazna vratila servo-motora. Jedan kraj nerastegljive sajle je namotan preko doboša. Drugi kraj sajle je ankerisan za određene tačke na segmentu robotske ruke. Na ovaj način, obrtno kretanje servo-motora je preneseno na linerno kretanje sajlice kako je to prikazano na šemi na Sl. 3.



Slika 1. Viši nivo prikaza žičanog pogona, višestruko aktuirane robotske ruke: a) struktura mehanizma i princip pogona; b) konstrukcija vođica (prolaznih ploča) namenjenih za sprovođenje poteznih sajli. Značenje pojedinih pozicija na slici: 1-DC-motor; 2-motorizovani kotur; 3- potezne sajlice; 4-sverni zglob u ramenu; 5-kuglični ležaj; 6-konični zupčanik; 7-kotur; 8-pronacija/supinacija nadlaktice; 9-vođica; 10-opruge; 11-Al-kućište; 12-graničnik elastičnog modula; 13-završna ploča prvog segmenta; 14-kotur; 15-konični zupčanik; 16-pronacija/supinacija podlaktice ; 17-opruge; 18-senzor momenta u zglobu (ramena, lakta, zgloba šake), 19-šaka; 20-DC-motor; 21-motorizovani doboš; 22-rameni zglob; 23-zglob lakta; 24-zglob šake; 25-prirubnica šake; 26- cenatar mase šake.

IV. MATEMATIČKI MODEL

Matematički model robotske ruke uključuje model mehanizma robotske ruke i model pogona. Konstruisani sistem je višestruko aktuiran pošto ima veći broj aktuatora nego što robot ima zglobova.



Slika 2. Konfiguracija pogonskog modula robotske ruke. Princip prenosa snage od servo-motora do zglobova robota: M1, M2 – savijanje/istezanje nadlaktice; M3, M4 – savijanje/istezanje podlaktice; M5 – savijanje/istezanje robotske šake; M6, M7 – odručenje/priručenje nadlaktice, M8 – odručenje/priručenje robotske šake; M9 – pronacija/supinacija nadlaktice and M10 - pronacija/supinacija podlaktice. Značenje pojedinih pozicija na grafičkoj prezentaciji je: 1-Al-kućište, 2-servo-motor Tipa A; 3-servo-motor Tipa B; 4-krajevi električnog konektora; 5-motorizovani doboš; 6-izlazno vratilo (DC-motor and planetarni reduktor); 7-nerastegljive sajle; 8-uležištenje; 9-sakupljač sajli i konduktor; 10-silikonska cevčica; 11-rupa; 12-izlazna konudktivna ploča; 13-sajla; 14-prirubnica ramenog zgloba; 15-istezanje zgloba; 16-okvir kućišta; 17-navojno vreteno kućišta; 18-navrtka.

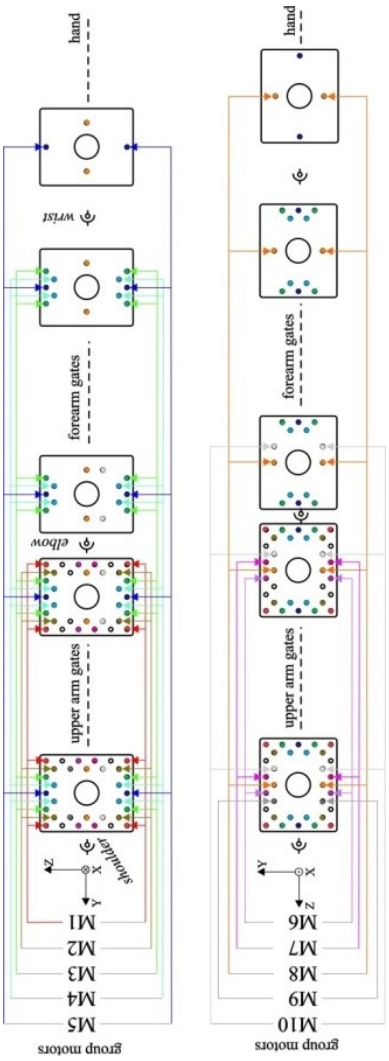
Model robota uključuje kinematski i dinamički model mehanizma. Kinematski model mehanizma opisan je jednačinama koje dovode u vezu unutrašnje koordinate robota iz prostora zglobova i spoljašnje koordinate iz prostora zadatka. Kinematski model se definiše sledećim relacijama:

$$s = f(q, p) \tag{1}$$

$$\dot{s} = J(q, p)\dot{q} \tag{2}$$

$$\ddot{s} = J(q, p)\ddot{q} + \frac{\partial J(q, \dot{q}p)}{\partial q}\dot{q}^2 \tag{3}$$

gde je: $q = [q_1\ q_2 \dots q_7]^T$ vektor unutrašnjih koordinata zglobova robota; $s = [x\ y\ z\ \varphi\ \theta\ \psi]^T$ je vektor spoljašnjih koordinata koje opisuju poziciju i orjentaciju završnog organa robota u prostoru zadatka (Kartezijanske koordinate *x, y, z* za poziciju i odgovarajući Ojlerovi uglovi *φ, θ, ψ* za orjentaciju);



Slika 3. Šema aktuacije robotske ruke – segmenta nadlaktice, podlaktice i šake. Potezne sajlice i odgovarajući otvori kao provodne vođice u robotskoj ruci.

$J(q, p)$ je Jakobijeva matrica dimenzija 6 x 7; Kinematski i dinamički parametri mehanizma su definisani vektorom *p*.

Dinamički model mehanizma robota je izražen u vektorskoj formi diferencijalnom jednačinom (4):

$$\tau = H(q, p)\ddot{q} + C(q, \dot{q}, p)\dot{q} + G(q, p) + \cdots + J^T(q, p)S + J^T(q, p)F \tag{4}$$

gde je $\tau = [\tau_1\ \tau_2 \dots \tau_7]^T$ vektor momenata u zglobovima robota; $H(q, p)$ je matrica inercije; $C(q, \dot{q}, p)$ je vektor Koriolisovih i centrifugalnih sila/momenata; $G(q, p)$ je vector gravitacionih sila i momenata; $J(q, p)$ je Jakobijeva matrica mehanizma; S je vektor elastičnih sila i momenata koji potiču od niza opruga i elastične strukture mehanizma; *F* je vektor spoljašnjih sila i momenata koje dejstvuju na mehanizam i *p* je vektor geometrijskih i dinamičkih parametara robotskog mechanizma. Pogonski momenti u zglobovima robota se ostvaruju na indirektan način, sinhronizovanim povlačenjem

sajli (Sl. 1, detalj 3). Sajle su jednim krajem povezane na pogonske motore koji su postavljeni u bazi. Drugi kraj kabla je fiksiran za mehaničku strukturu odgovarajućeg segmenta robota (Sl. 3). Pogonski momenti u zglobovima robotske ruke generisani su posredstvom odgovarajućih momenata na izlaznim vratilima servo-motora (Sl. 2). U relacijama (5)-(7) date su relacije koje dovode u vezu pogonske momente u zglobovima robotske ruke τ_j i odgovarajuće momente na izlaznim osovinama reduktora servo-motora.

$$\tau_1 = T_9, \tau_5 = T_{10} \tag{5}$$

$$\tau_2 = T_6 + T_7, \tau_6 = T_8 \tag{6}$$

$$\tau_3 = T_1 + T_2, \tau_4 = T_3 + T_4, \tau_7 = T_5 \tag{7}$$

U primeru koji se razmatra u ovom radu koristi se 10 servo-motora koji aktiviraju 7 zglobova robota i to: 3 u ramenu, 2 u laktu i 2 u zglobu šake robotske ruke. Model pogonskog motora uobičajeno se predstavlja sledećim relacijama:

$$L_r \frac{di_r}{dt} + R_r i_r + C_E \dot{q} = u \tag{8}$$

$$-C_M i_r + J_r \ddot{q} + B_C \dot{q} = -T_l \tag{9}$$

gde je: $L_r\ (H)$ induktivnost motora; $i_r\ (A)$ struja u rotoru; otpornost rotora $R_r\ (\Omega)$; konstanta proporcionalnosti elektromotorne sile $C_E\ (V/(\frac{rad}{s}))$; ugao obrtanja izlaznog vratila motora $q\ (rad)$; napon u rotoru $u\ (V)$; konstanta proprocionalnosti momenta $C_M\ (Nm/A)$; moment inercije motora J_M redukovan na izlazno vratilo $J_r\ (kg\,m^2)$; koeficijent viskoznog trenja redukovan na izlazno vratilo motora $B_C\left(Nm/(\frac{rad}{s})\right)$ i momenti od spoljašnjeg opterećenja $T_l\ (Nm)$. Konstante, C_E i C_M, koeficijent B_C i moment inercije J_r su određeni iz sledećih relacija: $C_E = C_e N_v$; $C_M = C_m N_m$; $B_C = B_c N_v N_m$; $J_r = J_m N_v N_m$ gde su N_v i N_m prenosni odnosi za moment i brzinu, redom, a C_e, C_m i B_c su uzeti iz kataloga proizvođača.

V. FUZZY KONTROLER

Momenti u zglobovima robotske ruke se ostvaruju dejstvom servo-motora postavljenih u osnovi robta (Sl. 1 i 2). U ovom slučaju, bazu robota predstavlja komplet od deset DC motora smeštenih u ramenom pojasu torzoa dvoručnog robotskog mehanizma koji će biti razvijen kao krajnji cilj projekta. Momenti na izlaznim vratilima motora se prenose do odgovarajućih zglobova robota posredstvom niza vođica (otvora u pločicama - kapijama) kroz koje prolaze potezne sajlice (Sl. 1). Na ovaj način, sinergijsko dejstvo dva motora se koristi da pokrene jedan stepen slobode kretanja mehanizma u pojedinom zglobu ruke. Ključno je pitanje kako izabrati pravu strategiju upravljanja redundantnim brojem pogona robotske ruke da bi se ostvarilo željeno kretanje mehanizma. U ovom radu biće prodiskutovana primena tri različite strategije aktuacije motora ali one nisu jedine koje je moguće definisati.

- Strategija ravnomerne raspodele opterećenja u zglobovima robota;
- Strategija kontrolisanog rada motora u nominalnom režimu, i
- Strategija raspodeljenog opterećenja motora među zglobovima.

Upravljački algoritam, koji ispunjava prvo navedenu strategiju ravnomerene raspodele opterećenja na servo-motorima koji pokreću pojedinačan zglob, obezbeđuje generisanje jednakih momeneta na izlaznim vratilima motora koji zajednički pokreću isti zglob ruke. Na bazi simulacionih rezultata u ovom radu, potvrđeno je da je ova strategija upravljnja najbolja u smislu postizanja najbolje energestke efikasnosti sistema.

Drugi predloženi algoritam, obezbeđuje rad motora u nominalnom režimu što generiše željene momente u zglobovima robota. To podrazumeva da neki od više motora, koji deluju sinergijski, ne mora biti aktivan kako bi ostali radili u nominalnim režimima.

Treći po redu upravljački algoritam, odgovoran za ostvarivanje postavljene strategije upravljanja, obezbeđuje da se za isti tip pokreta ruke (npr. priručenje/odručenje, savijanje/opružanje, itd.) opterećenje na motorima (više njih) tako raspoređuje da se mogu po potrebi koristiti i motori koji pokreću druge zglobove i ne pripadaju istoj grupi motra dodeljenih pojedinim zglobovima. Recimo, za savijanje zgloba u ramenu može se delimično koristiti aktivnost motora koji inače savija zglob u laktu ruke i na taj način „pomaže“ motorima ramena koji su realno najopterećeniji.

Inteligentni kontroler kretanja robotske ruke može kombinovati sve tri strategije od slučaja do slučaja u cilju postizanja boljih performansi sistema. Na sličan način funkcionišu i biološki sistemi gde se aktivnost mišića menja i prilagođava različitim uslovima manipulativog zadatka i opterećenja.

Na ovom mestu biće prikazano kako se sintetizuje fuzzy kontroler jedne prekobrojno pogonjene robotske ruke. Fuzzy kontroler ima četiri ulaza (ulazne promenljive) i dva izlaza. Ulazne promenljive fuzzy sistema su označene kao: „*Jtorq-gradient*“, „*M1-torq*“, „*M2-torq*“ i „*torq-deficit*“. Pomenute promenljive su definisane sledećim relacijama (10)-(13).

$$grad(\tau_k) = \frac{\Delta\tau_k}{\tau_k^{max}} \tag{10}$$

$$amp(T_j) = \frac{|\tau_j|}{\tau_j^{max}} \tag{11}$$

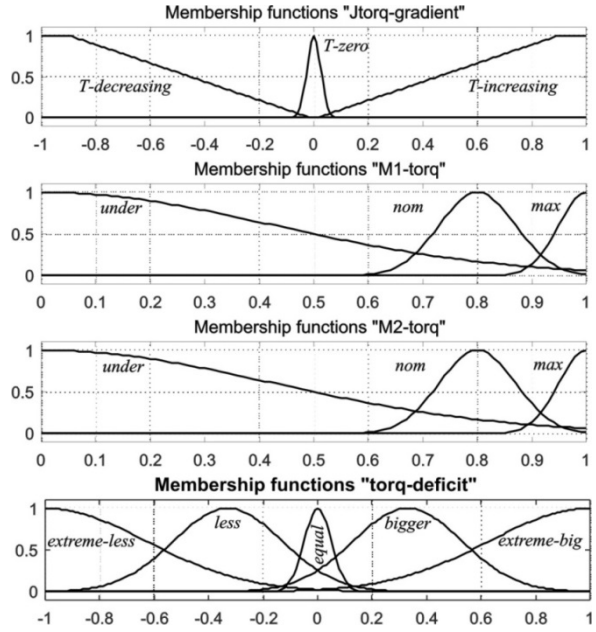
$$amp(T_{j+1}) = \frac{|\tau_{j+1}|}{\tau_{j+1}^{max}} \tag{12}$$

$$\Delta T_j^k = \frac{\tau_k - \tau_j}{\tau_j^{max} + \tau_{j+1}^{max}} \tag{13}$$

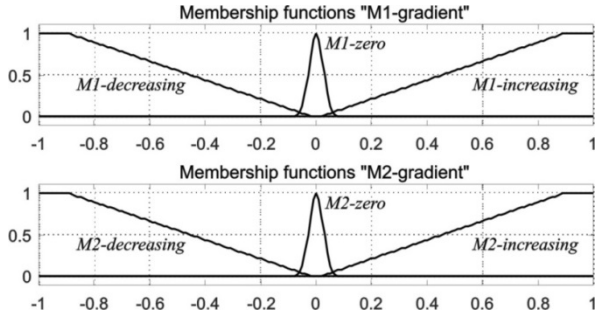
gde je: $grad(\tau)$ relativni gradijent momenta opterećenja τ_k koje dejstvuje u k-om zglobu robota; $amp(T_j)$ je relativni priraštaj amplitude momenta tzv. vodećeg „master“ servo-motora koji pokreće k-ti zglob robota; $amp(T_{j+1})$ je relativni priraštaj amplitude momenta pomoćnog (dopunskog) servo-

motora koji pokreće *k*-ti zglob ruke; ΔT_j^k je odstupanje (deficit/suficit) pogonskog momenta motora od odgovarajućeg momenta opterećenja u *k*-om zglobu robota. Izlazne promenljive fuzzy kontrolera T_j^k i T_{j+1}^k predstavljaju vrednosti pogonskih momenata generisanih na paru servo-motora M_j i M_{j+1} koji sinergijski pokreću k-ti zglob robotske ruke. U relacijama (5)-(7) dati su momenti opterećenja robotskog mehanizma τ generisani posredstvom odgovarajućih pokretačkih servo-motora $T_1 \cdots T_{10}$ svih zglobova mehanizma.

Struktura fuzzy kontrolera sastoji se od funkcija članstva čiji su oblici dati na Sl. 4 i 5.



Slika. 4. Ulazne promenljive i funkcije članstva projektovanog fuzzy kontrolera.



Slika 5. Izlazne promenljive i funkcije članstva projektovanog fuzzy kontrolera.

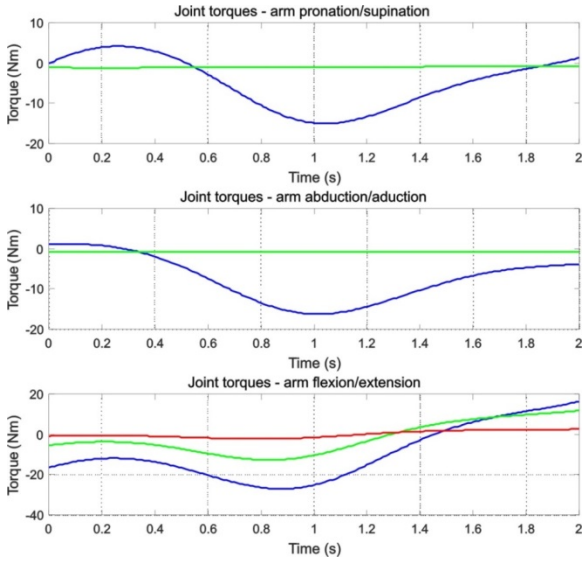
Logički deo kontrolera čini 11 fuzzy pravila koja uzimaju u obzir ranije definisane ulazne i izlazne promenljive. Uvedena fuzzy pravila materijalizuju stanja sistema koja ispunjavaju odgovarajuće postavljene kriterijume funkcionisanja. To su: a) kriterijum nominalnog režima rada koji vodi računa da motori rade uvek u optimalnom modu rada, ili b) kriterijum ravnomerne raspodele opterećenja među motorima. Na Sl. 6 prikazani su rezultati primene inteligentnog robotskog kontrolera, na najvišem nivou upravljanja, za slučaj ispunjenja kriterijuma a). U radu se razmatra slučaj kada tri para servo-motora (M6, M7), (M1, M2) i (M3, M4) rade u „kooperativnom“ režimu rada odn. sadejstvu. Za taj slučaj se u ovom radu prikazuju odgovarajući simulacioni rezultati. Uočava se da glavni (master) motori M6, M1 i M3 pretežno rade u nominalnom režimu rada (s približno 80% snage) kada je njihova efikasnost najveća. Istovremeno, pomoćni, dopunski motori M7, M2 i M4 (Sl. 2 i 3) su manje opterećeni. Zadatak pomoćnih motora je da nadomeste eventualni deficit u snazi glavnih motora. Zajedno, glavni i pomoćni motori obezbeđuju sprovođenje željenog kretanja zglobova robotskog mehanizma.

Fuzzy pravila koja obezbeđuju realizaciju postavljenog niza kriterijumskih funkcija su:

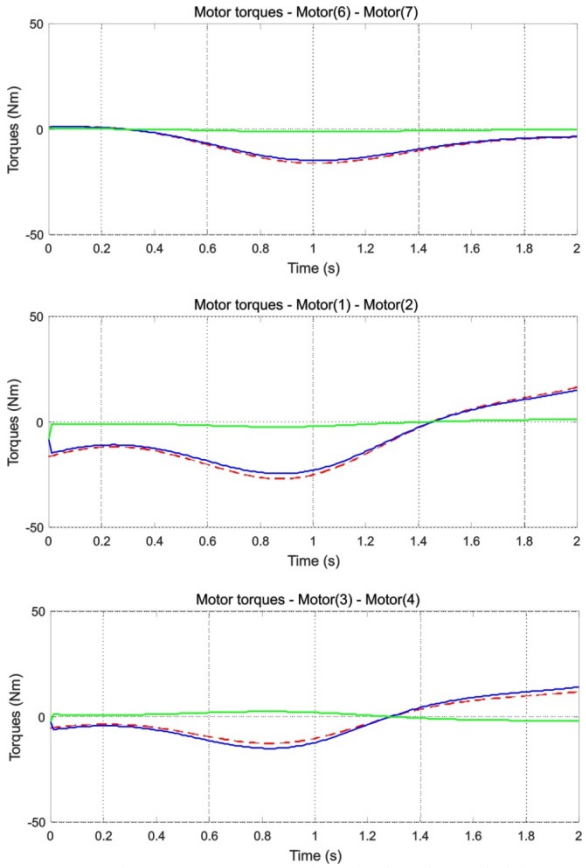
1. If (Jtorq-gradient is T-zero) then (M1-gradient is M1-zero) and (M2-gradient is M2-zero) (1)
2. If (Jtorq-gradient is T-increasing) and (M1-torq is not nom) then (M1-gradient is M1-increasing) (1)
3. If (Jtorq-gradient is T-decreasing) and (M1-torq is not nom) then (M1-gradient is M1-decreasing) (1)
4. If (M1-torq is max) then (M1-gradient is M1-zero) (1)
5. If (M2-torq is max) then (M2-gradient is M2-zero) (1)
6. If (M1-torq is not max) and (M2-torq is not max) and (torq-deficit is extreme-big) then (M1-gradient is M1-increasing) and (M2-gradient is M2-increasing) (1)
7. If (M1-torq is not max) and (M2-torq is not max) and (torq-deficit is extreme-less) then (M1-gradient is M1-decreasing) and (M2-gradient is M2-decreasing) (1)
8. If (Jtorq-gradient is T-increasing) and (M1-torq is nom) and (M2-torq is under) then (M1-gradient is M1-zero) and (M2-gradient is M2-increasing) (1)
9. If (Jtorq-gradient is T-decreasing) and (M1-torq is nom) and (M2-torq is under) then (M1-gradient is M1-zero) and (M2-gradient is M2-decreasing) (1)
10. If (Jtorq-gradient is T-increasing) and (M1-torq is nom) and (M2-torq is nom) then (M1-gradient is M1-increasing) and (M2-gradient is M2-increasing) (1)
11. If (Jtorq-gradient is T-decreasing) and (M1-torq is nom) and (M2-torq is nom) then (M1-gradient is M1-decreasing) and (M2-gradient is M2-decreasing) (1)

VI. SIMULACIONI REZULTATI

S ciljem da se odrede momenti opterećenja u zglobovima robota i da se sračunaju pogonski momenti u servo-motorima, urađeni su odgovarajući simulacioni eksperimenti. Zadat je robotu jedan tipičan manipulativni zadatak gde se od robota zahtevalo da napravi pokret u vertikalnoj ravni protivno sili gravitacije i da pri tom nosi teret u hvataljci težine 3 kilograma. To predstavlja jedan od najzahtevnijih robotskih zadataka, u smislu opterećenja, koja se javljaju u zglobovima mehanizma. Model robota, definisan relacijama (1)-(4) je iskorišćen za simulaciju kinematskih i dinamičkih efekata. Simulacioni rezultati su prikazani na Sl. 6 i 7.



Slika. 6. Momenti opterećenja u zglobovima robota za vreme savijanja ruke u vertikalnoj ravni suprotno ubrzanju gravitacije.



Slika 7. Momenti servo-motora generisani tako da savladaju momente opterećenja u zglobovima robotskog mehanizma (u primeru robotskog zadataka koji je obrađen u tekućem simulacionom primeru važećem i na Sl. 6). Grafik prikazan isprekidanom linijom predstavlja momente u zglobovima robotske ruke.

VII. ZAKLJUČAK

Višestruko pogonjen robotski sistem ima značajne prednosti nad konvencionalno aktuiranim sistemima (jedan zglob – jedan motor). Prednosti se ogledaju u sledećem. Kada prekobrojno aktuiran sistem ima kvar na pojedinom servo-motoru, preostali pogoni preuzimaju teret (odgovornost) da omoguće da sistem i dalje regularno radi čak i pri smanjenom kapacitetu snage. Druga prednost se odnosi na mogućnost da se kod prekobrojno pogonjenih sistema mogu na pogodan način primeniti različiti optimizacioni, inteligentni algoritmi upravljanja koji minimizuju potrošnju energije, koordiniraju radom servo-motora tako što ih teraju da funkcionišu u nominalnom režimu rada tako da ih štede i produžavaju radni vek. Treća prednost ovih sistema odnosi se na kompaktnost konstrukcije i racionalizaciju prostora potrebnog za smeštanje pogonskih motora u mehanizmu. Predložena je i potvrđena simulacionim eksperimentima upotreba većeg broja slabijih pogona (redundantsnost u broju motora) nasuprot manjem broju, po dimenzijama većih i snažnijih motora. Ako smo svesni činjenice da se kod bioloških sistema koristi veći broj mišića za pokretanje jednog zgloba onda se pristup konstruisanju robotske ruke u ovom radu smatra opravdanim i u saglasnosti s poznatim bio-kibernetskim principima funkcionisanja živih bića.

ZAHVALNOST

Ovaj članak je rezultat rada na istraživačkom projektu "Istraživanje i razvoj ambijentalno-inteligentnih robotskih sistema antropomorfne strukture" pod brojem TR-35003, 2011-2019 koje finansira Ministarstvo prosvete, nauke i tehnološkog razvoja Republike Srbije.

Аутоматизација система за наводњавање применом Интернета ствари

Владо Крунић, *ПМФ, Универзитет у Бањој Луци,* Момчило Крунић, *ФТН, Универзитет у Новом Саду,* Предраг Ранитовић, *Висока пословна школа струковних студија Нови Сад*

***Апстракт*— Интернет ствари (IoT – Internet of Things) је довео до великих промена свакодневног живота људи кроз примену у градовима, енергетици, пословању, образовању, медицини, индустрији, пољопривреди и другим областима. Интернет ствари омогућује повезивање већег броја корисника, уређаја, сервиса и апликација на Интернет, при чему се сваком уређају додељује јединствен идентификатор. Међусобно повезани уређаји и апликације размењују податке и прослеђују их удаљеним серверима, да би им крајњи корисници приступали по потреби путем мобилних и/или веб апликација. Примена IoT у пољопривреди кроз пројектовану инфраструктуру са одређеним сензорима, актуаторима, микроконтролерима и микрорачунарима омогућује се стални надзор и аутоматско покретање одговарајућих процеса. Кључне активности, које се ефикасно могу аутоматизовати применом IoT, се односе на процесе наводњавања. Тема рада је модел аутоматизације система за наводњавање применом IoT.**

***Кључне речи* - *И*нтернет ствари; Дизел генератор; Систем за наводњавање; Сензор; Актуатор.**

I. Захтеви корисника

Интернет свари (IoT – Internet of Things) представља концепт који омогућава објекима из реалног света, који имају рачунарску и сензорску подршку, да се међусобно повежу и да приступе апликацијама и сервисима на Интернету. IoT треба да, посредством Интернета, повеже уређаје и да омогући корисницима приступ и размену информација. Једна од области са већом потенцијалном употребом IoT је пољопривреда где се и убудућности може очекивати још шира примена [1], [2].

Циљ овог рада је да се представи IoT концепт на коме је заснован систем за даљинско надгледање и контролу процеса наводњавања. Систем за наводњавање који треба аутоматизовати применом Интернета ствари се састоји из следећих уређаја и инфраструктурне опреме:

- Дизел генератор електричне енергије, трофазни;
- Пумпа за наводњавање за бунар, трофазна;
- Фреквентни регулатор, трофазни;
- Разводни ормар са главним прекидачем, осигурачима и одговарајућом инсталацијом;
- Разводни систем са три кугласте славине за воду са прикључцима пречника 50 mm;
- Систем цеви за наводњавање три парцеле;

Први и основни захтев корисника се може изразити кроз реченицу: Дизел генератор електричне енегрије (у даљем тексту Агрегат) треба реконструисати са доградњом одговарајућих уређаја који ће омогућити његово стартовање, надзор и гашење на даљину.

Други захтев се односи на даљинско стартовање пумпе, надзор њеног рада и гашење по истеку подешеног временског периода или на захтев.

Трећи захтев подразумева постављање сензора за влажност на одговарајућим местима и праћење параметара влажности на три локације које се независно наводњавају.

Осим наведена три основна захтева, потребно је унапредити разводни систем уградњом електомагнетних вентила који ће се селективно отварати/затварати према потреби, односно захтеву апликације.

Такође, треба поставити систем видео надзора са циљем повећања безбедности и заштите система за наводњавање, као и објекта за смештај главне опреме.

II. Анализа опреме и захтева

Први корак у реализацији захтева корисника се односи на анализу структуре и функција расположиве опреме и сагледавање могућности њеног унапређења са циљем стварања услова за испуњење постављених захтева. Полазна тачка је први захтев корисника и прва ставка наведене расположиве опреме. Дакле, анализираћемо могућности реконструкције и доградње расположивог дизел генератора – Агрегата (Слика 1). Агрегат је марке Willager, номиналне снаге 5,5 kW.

Сл. 1. Дизел генератор електричне енергије марке Willager, ознаке VGD5500-0. Мотор се стартује преко контакт браве електропокретача (анласера) повезаног на акумулатор 12V, капацитета 20 Ah. Контакт брава има три положаја (0 – нема нема контакта, 1- спреман за палење и 2 – покретање анласера).

Агрегат који је представљен располаже са дизел мотором снаге 7,4 kW, који постиже брзину од 3600 rpm. Пали се електропокретачем или ручно, потезањем стартног ужета. Палење, као и гашење дизел агрегата је много сложеније у односу на бензинске агрегате.

Агрегат који се користи у систему за наводњавање има техничке карактеристике које могу да задовоље

корисничке захтеве везане за аутоматизацију (Табела I).

ТАБЕЛА I
КАРАКТЕРИСТИКЕ АГРЕГАТА

Тип мотора	Четворотактни, ваздушно хлађени
Запремина мотора	418 cm³
Снага мотора	7.4 kW (3600 rpm)
Тип стартера	Реверзибилни / Електро-старт
Номинална снага kW	5 kW
Максимална снага kW	5.5 kW
Јачина ел. струје	8.3 A
Номинални напон	230 V / 400 V
Утичнице	1 × 230 V / 1 × 400 V
Време рада	≈ 9 h 30 min.
Гориво	Дизел
Маса	120 kg
Запремина резервоара	15 l

Наводимо два проблема која су идентификована код решавања аутоматизације:

А. Дизел агрегати имају ручицу којом се отвара довод горива непосредно пре палења. Агрегат се гаси тако што се затвори довод горива. Затварање довода горива је аутоматизовано померањем контакт кључа из позиције 1 на позицију 0. Потребно је осмислити решење које омогућује даљинско отварање довода горива.

Б. Дизел агрегати се теже пале у зимским условима, па је некад потребно да се више пута стартују док се не упале. Приликом ручног стартовања треба претходно повући ручицу за декомпресију ради лакшег почетног покретања мотора. Декомпресија је пожељна и код палења преко стартера (анласера), ради смањења почетног обртног момента. Треба наћи решење да се ручица за декомпресију аутоматски повлачи.

Сценарио палења Агрегата је следећи: 1 – Отвара се славина за гориво повлачењем ручице. 2 – Повлачи се ручица за декомпресију мотора. 3 – Кључ стартне брава се из позиције 0, помера на позицију 1, а затим се помера на позицију 2. На позицији 2 кључ се задржава од 2 до 4 секунде, а затим се враћа на позицију 1. Ако се мотор не упали, посутпак се понавља.

После палења (или непосредно пре палења) Агрегата, проверавају се линије за наводњавање и евентуално се подешавају за наводњавање одређене парцеле. Избор парцеле је условљен процентом влажности.

После стабилизације рада мотора у периоду од 5 до 10 s, трофазни прекидач фреквентног регулатора се поставља у контакт позицију чиме се пумпа за воду. Агрегат се гаси постављањем прекидача стартне браве у нулту позицију чиме се активира механизам за затварање довода горива.

Пумпу за воду коју покреће Агрегат, спада у групу посебних пумпи намењених за транспорт воде из бунара. То је такозвана потапајуће пумпе за бунаре, Pedrollo 4SR8/13, са уљним мотором предвиђеним за дуг временски рад. Услови рада пумпе су предвиђени за бунаре који имају значајне залихе воде (Табела II).

Снага пумпе (2,2 kW) је усклађена према капацитету бунара и укупној површини парцела који треба наводњавати (2,7 ha) технологијом „кап по кап“ [7].

III. НАДОГРАДЊА СИСТЕМА ЗА НАВОДЊАВАЊЕ

Треба подсетити да Агрегат поседује техничке карактеристике које су у складу са потребама напајања пумпе, уз нешто резерве снаге што је пожељно ради повећане потрошње код стартовања пумпе као и напајања додатне опреме. Између Агрегата и пумпе је смештен фреквентни регулатор који регулише рад пумпе и оптимизује потрошњу горива. Пумпа је повезана на разводни систем са три кугласте слине којима се према потреби отварају или затварају линије за наводњавање три посебне парцеле.

Резултати претходне анализе расположиве опреме и захтева корисника упућују на неколико техничких захвата који подразумевају пре свега доградњу механизама који ће омогућити аутоматизацију појединих операција. На самом почетку анализе проблема наведеног под А. намећу се два решења:

1. Даљинско померање ручице славине за отварање довода горива се може извести уградњом вентила одговарајуће снаге са елетромагнетним актуатором повезаним на акумулатор 12 VDC.

2. Друго решење је доградња електромеханичког уређаја непосредно поред ручице славине за ручно затварање довода горива, који ће моћи да помера ручицу славине. Свако од решења има предности и недостатке.

Наш избор је решење са уградњом електромагнетног актуатора (Слика 2), због неколико разлога:

- Постојећа линија довода горива остаје у оригиналној изведби, што је увек пожељно због будућег одржавања;
- Доградња електромеханичког уређаја који покреће ручицу постојеће славине је јефтиније него набавка новог електромагнетног вентила и његова уградња;
- Електромеханички уређај је довољно поуздан и његово одржавање је једноставније него одржавање електромагнетног вентила.
- Решење опције избора палења Ручно/Аутоматско, је једноставно (реконструкција Агрегата подразумева да постоји опција избора палења Ручно/Аутоматско).

ТАБЕЛА II
КАРАКТЕРИСТИКЕ ПУМПЕ

Модел	4SR8/13
Тип пумпе	Потапајућа бунарска 4"
Потис	2"
Снага	2200 W
Напон	380 V
Напор	85 - 30 m
Проток	40 ~ 200 L/min
Потапање	Макс. 100 m
Температура воде	Макс. +35°C
Температура околине	Макс. +35°C
Димензије (Ø x H)	98mm x 1043mm
Тежина	19,2 kg

Анализом је установљено да треба осмислити и направити електромеханички механизам за померање ручице славине за отварање линије за довод горива.

Механизам који је направљен, тестиран и који функционише без грешке се састоји од електромагнета

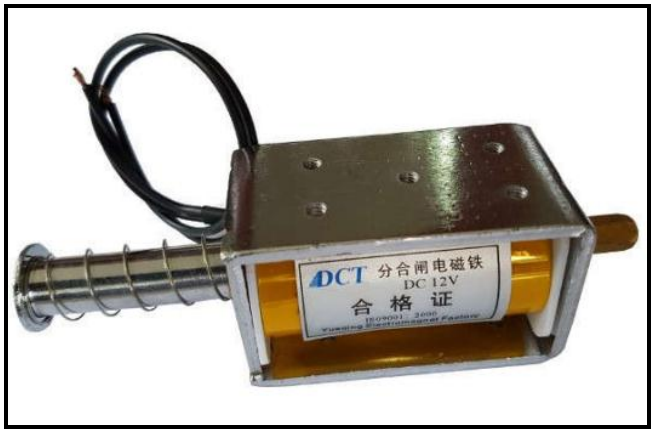
одговарајућих карактеристика, носача електромагнета постављеног на кућиште Агрегата и полуге која повезује електромагнет и ручицу славине на линији за довод горива. Карактеристике електромагнета су у складу са захтевима који дефинишу момент силе за затварање славине на линији за довод горива и дужину лука кружног кретања ручице славине (Табела III).

ТАБЕЛА III
КАРАКТЕРИСТИКЕ ЕЛЕКТРОМАГНЕТА

Модел	DCT 150
Добављач	DOSSY
Напон	12VDC
Ход	30 mm
Сила (ход 0)	2 kg
Сила (ход 30 mm)	0.15 kg
Тип	Push

Осим описаног механизма за аутоматско отварање ручне славине на линији за довод горива, потребно је осмислити и направити и механизам за декомпресију Агрегата. Решење уоченог проблема (наведеног под Б. у анализи опреме и захтева) је скоро исто као претходно описано решење аутоматизације ручног вентила на линији за довод горива, осим разлике у начину фиксирања електромагнета на кућиште Агрегата.

Механизам за аутоматску декомпресију се разликује у конструкцији носача електромагнета у односу на механизам за отварање ручне славине за гориво. Електромагнетни актуатори се не разликују с обзиром на врло сличне техничке захтеве за конструкцију наведених механизама. Осим тога, оба електромагнетна актуатора се покрећу помоћу акумулатора 12 VDC.



Сл. 2. Електромагнет DCT150 12VDC је коришћен као актуатор у уређају за аутоматско покретање ручног вентила за гориво. Исти такав електромагнет се користи као актуатор који повлачи полугу за декомпресију. Поузданост је експериментално потврђена оптерећењем електромагнета двоструко већим од захтеваног.

Претходно описани механизми за аутоматско отварање довода горива и аутоматску декомпресију су тестирани у радним условима тако што су активирани затварањем струјног кола где је извор напајања акумулатор Агрегата. Радни услови за тестирање уграђених електромагнетних механизама су остварени у режиму ручног управљања.

Наредни корак који је предузет у процесу решавања захтева корисника се односи на анализу електричних кола чија се стања мењају променом позиција контакт кључа стартне браве Агрегата. Идеја аутоматизације дефинисане корисничким захтевима је заснована на идентификацији свих могућих стања електричних кола која се отварају или затварају различитим позицијама контакт кључа у стартној брави.

IV. ЛОГИКА СТАРТОВАЊА АГРЕГАТА

Основна идеја која се односи на аутоматизацију Агрегата, који се пали помоћу контакт кључа стартне браве са три могућа положаја (0, 1 и 2), је заснована на симулацији позиционирања контакт кључа. У ту сврху, треба пресећи све каблове који су повезани на стартну браву и направити „Т“ везу која ће омогућити опцију Ручно/Аутоматско палење.

Када се изабере опција Ручно палење, враћамо се на оригинално повезаивање и прекидање веза које воде до система за аутоматско палење. Избор опције Аутоматско палење прекида све везе до контакт браве и повезује каблове који воде до система за аутоматско палење. Следи идентификација електричних кола и опис логике система ручног палења Агрегата.

Идентификација стања електричних кола је заснована на анализи и мерењу стања контакта која се реализују променом позиција контакт кључа стартне браве, узимајући у обзир и смер окретања стартног кључа. Са стартном бравом је повезано пет каблова (црни, жути, сиви, бели и црвени), којима се успостављају различита електрична кола дефинисана шемом електро инсталације система палења Агрегата.

Стартни кључ има три могућа положаја (Положај 0, Положај 1 и Положај 2) преко којих се успостављају или раскидају везе између каблова према опису који следи:

Положај 0 је безконтактни (црна и жута жица спојене, док су све друге растављене).

Положај 1 је контактни (када се окрене кључ у смеру кретања казаљки на сату на прву попозицију (прекида се веза црне и жуте жице и спајају се сива и бела жица)

Положај 2 је контакт за електропокретач (анласер). Овај положај се добије када се савлада опруга кретањем стартног кључа у смеру казаљки на сату полазећи из позиције Положај 1. У овом положају се црвена жица спаја са белом и сивом жицом на кратко време од 2-3 секунде, када треба да се упали Агрегат. После палења пустимо стартни кључ да га опруга врати у Положај 1 где остаје док све док Агрегат ради.

Ако се Агрегат не упали после 2-3 секунде, кључ стартне браве треба вратити у Положај 1 и поново стартовати електропокретач. Гашење агрегата се изводи враћањем контакт кључа стартне браве на Положај 0, чиме се активира затварање довода горива.

Претходна анализа стартне браве је довољна за дефинисање управљачке логике аутоматског стартовања Агрегата, што подразумева испуњавање првог захтева корисника. У наставку је представљена управљачка логика аутоматског система за наводњавање.

Логика аутоматског палења Агрегата треба да буде идентична ручном палењу које смо описали. Мобилна IoT апликација eWeLink, која омогућава комуникацију,

подешавање и управљање Sonoff паметним уређајима, је подешена према захтевима управљачке процедуре система наводњавања. Структура управљачког модула садржи следеће нивое:

Највиши ниво чини eWeLink апликација (интерфејс између корисника и управљачког хардвера), затим следи слој који обухвата Sonoff IoT уређаје, наредни слој (испод Sonoff uređaja) се састоји од електронске плочице и два електромагнета (актуатори славине на доводу горива и вентила за декомпресију). Карактеристике датих електромагнета су наведене у претходном поглављу у оквиру описа електромеханичких уређаја који су уграђени у Агрегат. Остали део опреме за аутоматско палење обухватају три уређаја:

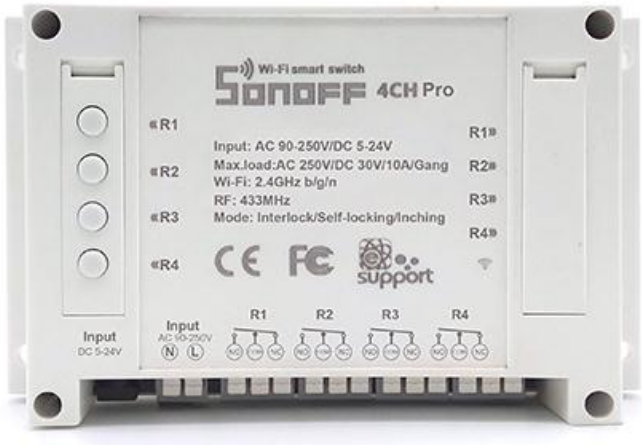
1. Електронска плочица RST-SW/2R12V/2R220V

Електронска плочица садржи RST склопку са 3 релеја 12V/16A, којом се покреће фреквентни регулатор за пумпу. Трофазна склопка се активира сигналом 12 VDC помоћу R3 релеја Sonoff 4CH Pro микроконтролера, са спецификацијом представљеном у наставку. Осим тога на плочици се налази и 4 релеја за управљачку логику: 2 релеја 12V/16A за стартне контакте (RS1 и RS2), 1 релеј 220V/16A намењен за раскидање струјног кола електропокретача ако је агрегат упаљен (RE) и 1 релеј 220V/16A (RP), који служи за покретање пуме за наводњавање помоћу SonoffTH10/TH16 прекидача.

2. Sonoff 4CH Pro – микроконтролер (Слика 3)

Спецификација:

Радни мод: inching/interlock/self-locking mode
Подесиво време: 0.25-4s
Напајање: 5-24V DC
Макс. струја: 10A
Макс. снага: 2200W
Wireless стандард: Wi-Fi 2.4GHz b/g/n, 433MHz RF
Заштита: WEP/WPA-PSK/WPA2-PSK



Сл. 3. Sonoff 4CH Pro је микрокомтролер са 4 релеја која се могу подешавати на апликативном нивоу према захтевима управљачке логике. Техничке карактеристике су у складу са потребама система за аутоматско наводњавање.

3. SonoffTH10/TH16 - паметни прекидач (Слика 4)

Спецификација:

Напајање: 90V~250V AC
Макс. струја:16A
Wireless стандард: WiFi 2.4GHz b/g/n
Заштита: WEP/WPA-PSK/WPA2-PSK
Оперативна температура: 0℃~40℃
Оперативна влажност: 5%-95%
Материјал: FR-ABS

Сл. 4. SonoffTH10/TH16 је паметни прекидач са једним релејем који се користи за покретање потапајуће пумпе. Осим тога, овај прекидач има и сензоре за мерење влажности и температуре који се користе за аутоматско управљање процесом наводњавања.

V. Мобилна апликација

Интерфејс мобилне апликације eWeLink садржи четири дугмета за палење Агрегата и видео надзора и једно дугме за покретање пумпе система за наводњавање. Прва три дугмета (Дугме 1, Дугме 2, Дугме 3) су непосредно везана редом за релеје микроконтролера Sonoff 4CH Pro, са ознакама R1, R2 и R3, респективно, којима се активирају одређени уређаји система за наводњавање. Дугме 4 мобилне апликације eWeLink је везано за четврти релеј микроконтролера Sonoff 4CH Pro, са ознаком R4, којим се активира видео надзор објекта са опремом система за наводњавање.

Пето дугме апликацие eWeLink је везано за паметни прекидач SonoffTH10/TH16, који је предвиђен за покретање потапајуће пумпе активирањем трофазног прекидача уграђеног у фреквентни регулатор, посредно преко релеја RP 220V/16A који се налази на електронској плочици RST-SW/2R12V/2R220V.

Дугме 1 (КОНТАКТ) доводи до стања које је адекватно стању Положај 1 код ручног палења (раскида се веза црне и жуте жице и спајају се сива и бела жица. Ово се дешава на електронској плочи где се истовремено напајају релеји RS1 и RS2. RS1 релеј раскида нормално затворено коло - раздваја црну и жуту жицу, док RS2 релеј спаја нормално отворено коло - спаја сиву и белу жицу. Поновни клик на Дугме 1 (гашење) враћа претходно стање адекватно Положај 0 ручног палења (Слика 5).

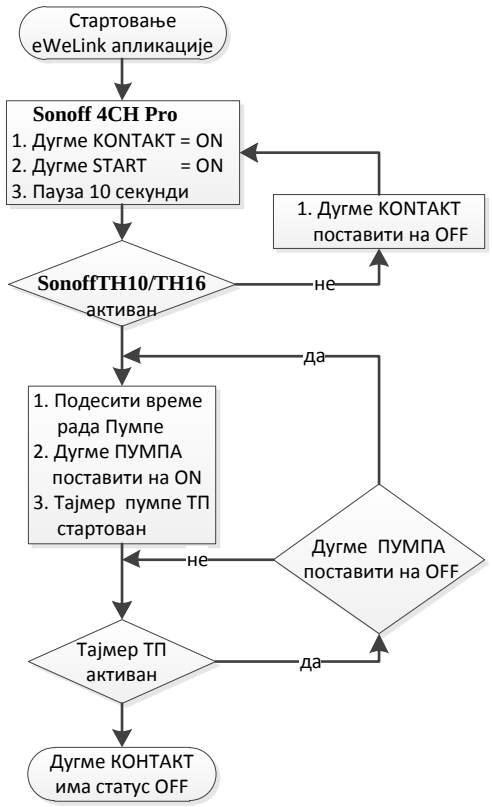
Дугме 2 – (СТАРТ) долазимо до стања које је адекватно стању Положај 2 код ручног палења. У овом положају, који следи после клика које активира Дугме 1, долази до спајања црвене и сиве жице које траје 2-4 секунде, зависно од сетовања (претходно су спојене сива и бела жица када смо активирали Дугме 1).

Црвена жица се спаја са сивом преко R2 релеја Sonoff 4CH Pro који се напаја кликом на Дугме 2 у апликацији

мобилног телефона. Црвена жица из стартне браве се спаја са средњим контактом који је заједнички за нормално отворен и нормални затворен излаз.

Са нормално отвореног контакта црвена жица одлази до електронске плоче на релеј RA3-220V/16A за укидање контакта електропокретача, ако је упаљен агрегат. Црвена жица пролази кроз нормално затворен контакт до сиве жице на шини у разводном орману. Када се агрегат упали раскида се веза која спаја црвену и сиву жицу.

Дугме 3 (ПУМПА) пали фреквентни регулатор преко кога се покреће трофазна пумпа. Ово дугме се активира увек после палења агрегата. Провера да ли је агрегат упаљен се ради тако што се погледа да ли је уређај SonoffTH10/TH16 активан (прослеђује информацију о портошњи струје).



Сл. 5. Блок дијаграм даљинског покретања система за наводњавање применом IoT апликације eWeLink повезане са описаном опремом за управљање Sonoff 4CH Pro и SonoffTH10/TH16.

VI. Интернет комуникација

Стигли смо до слоја који треба да нам омогући комуникацију преко Интернета. Кључну улогу у Интернет комуникацији има рутер намењен мобилним корисницима, као и корисницима стационираним у руралним подручјима. Наравно, подразумевано је да на локацији где желимо да приступамо Интернету постоји довољно јак сигнал мобилног оператера чије услуге намеравамо да користимо. Из богате понуде различитих комуникационих уређаја издвојили смо Huawei E5573 4G Mobile Wi-Fi рутер који је робусан, поуздан и једноставан за инсталацију. Намењен је за кориснике у подручјима где није доступна кабловска комуникација.

Спецификација рутера:
Димензије (mm): 94 x 58 x 15mm
Тежина (g): 75.00
Модем: 4G
Капацитет батерије (mAh): 1500
Меморијско проширење (GB): 32GB
Брзина: до 150Mbps download, до 50Mbps upload
LTE категорија: LTE CAT4
LTE фреквенције: (800/900/1800/2100/2600MHz)
WLAN standards: 802.11a/b/g/n
5 GHz WLAN подршка: Да
Заштита (енкрипција): WEP, WPA, WPA2

Непрекидно напајање је обезбеђено преко квалитетног пуњача за мобилне телефоне који се користе у аутомобилима. Комуникација је обезбеђена преко мобилног оператера који има сигнал довољно јак на локацији где је постављен рутер са SIM картицом.

Важно је нагласити да је систем комуникације потпуно аутономан са сталним напајањем преко акумулатора Агрегата који се допуњава, сваком приликом када је агрегат упаљен током процеса наводњавања. Интернет је доступан у сваком тренутку, што је потребан услов за функционисање управљачког система заснованог на IoT.

Слике 6, 7 и 8 представљају локацију примене IoT апликације и детаље опреме управљачког система.

Сл. 6. Пољопривредна парцела 2,7 ha са засадом малине у Бечејском атару са детаљем вентилације шахта у коме је смештен систем за наводњавање и опрема управљачког система. У белој кутији је смештен рутер који мора бити вани због сигнала мобилне мреже.

Сл. 7. Део шахта са Агрегатом где се види механизам за декомпресију са електромагнетним актуатором DCT150 12VDC. Са леве стране се види детаљ изолованог цевовоа за издувне гасове којим се гасови одводе ван просторије са опремом.

Сл. 8. Фреквентни регулатор за пумпу, паметни прекидач SonoffTH10/TH16 , микроконтролер Sonoff4CHPro и део инсталације у управљачком ормару система за наводњавање.

VII. ZAKLJUČAK

Пројекат аутоматизације система за наводњавање применом Интернета ствари, који је представљен у раду, је практично реализован на пољопривредној парцели у Бечејском атару. Систем наводњавања је „кап по кап“ типа, покрива парцелу од 2,7 ha, снабдева се бунарском водом и у експлоатацији је већ годину дана. Корисници управљају наводњавањем из Новог Сада и до сада нису имали примедби. Недостаци који су се појавили у току имплементације су отклоњени током тестирања, које је обављено пре пуштања унапређеног система у рад.

Аутори су предложили оригинално решење даљинског стартовања Агрегата са дизел горивом. Техничко решење обухвата доградњу два механизма са електромагнетним линеарним актуаторима:

- механизам за отварања ручне славине на линији за довод горива и
- механизам за отварање вентила за декомпресију.

Поред наведеног, инсталацији система за даљинско стартовања Агрегата је претходила реконструкција електро-инсталације Агрегата и разводног ормара са уградњом склопке за алтернативни избор стартовања Агрегата (ручно/аутоматско).

У припремне техничке захвате спада и обезбеђивање сталне Интернет везе са аутономним напајањем.

На крају, требало је на тржишту расположиве опреме одабрати поуздану опрему са перформансама које су у складу са захтевима корисника у које спада и економска оправданост аутоматизације система за наводњавање.

Идеја о унапређењу постојећих техничких система, као што је систем за наводњавање који је био тема рада, и њихова адаптација да се створе услови за примену савремених информационих технологија, као што је Интернет ствари, је кључни допринос рада. Осим тога, анализа система за стартовање Агрегата помоћу кључа стартне браве и идентификација електричних кола која се затварају/раскидају позиционирањем стартног кључа, је модел који може послужити у сличним ситуацијама које се односе на аутоматизацију техничких система.

Даље унапређење система за наводњавање се односи на уградњу аутоматских вентила за селективно наводњавање које је пожељно када се на различитим парцелама гаје различите врсте засада. Осим тога, треба поставити мрежу сензора који ће давати константне информације о различитим параметрима на одређеним парцелама [3] [4].

Са наведеном опремом се могу направити регулациони кругови и потпуно аутоматизовати систем наводњавања, који тренутно захтева мануелно подешавање линија за заливање. Постојећи систем треба интегрисати са новим функционалностима кроз јединствену веб апликацију [5], [6], [8] .

ABSTRACT

Internet of Things (IoT) has led to major changes in the daily lives of people through application in cities, energy, business, education, medicine, industry, agriculture and other fields. The Internet of things allows the connection of a large number of users, devices, services and applications to the Internet, whereby each device is assigned a unique identifier. Interconnected devices and applications share data and forward them to remote servers so that end-users can access them as needed via mobile and / or web applications. The application of IoT in agriculture through the projected infrastructure with appropriate sensors, actuators, microcontrollers and microcomputers enables continuous monitoring and automatic start of the appropriate processes. Key activities, that can be efficiently automated using IoT, refer to irrigation processes. The theme of the paper is the model of automation of irrigation systems using IoT.

Automation of irrigation systems using the Internet of Things

Data Acquisition, Collection and Storage in Smart Home Solutions

Sandra Ivanović, Neven Jović, Marija Antić, Ištvan Papp

***Abstract* — In this paper, one solution for smart home IoT data collection and storage is presented. In the proposed solution, MQTT protocol is used to report changes in the system, while RabbitMQ, MongoDB, and NodeJS are used on cloud side to capture, process and store data. Processed data is stored in views that can be easily retrieved and presented on the client side. The proposed solution does not introduce significant deployment and maintenance costs, as it does not introduce technologies that are not otherwise already present in the system. Performance of the proposed solution is explored, and it is shown that the rate of changes that can be captured satisfies the needs of the medium sized IoT system.**

***Index Terms*—data acquisition; smart home automation; big data, IoT**

I. Introduction

Recently, we have been witnessing the growing popularity of various IoT systems and applications, such as fitness companions, daily activity trackers, navigation services, etc. One of the IoT areas which is of particular interest to consumers is the field of home automation [1], [2]. Home automation (HA) solutions allow users to connect multiple sensing and actuating devices into one system, to monitor their state, perform actions, or setup automatic execution of some tasks. Depending on the HA system, single networking technology can be used to connect devices [3], [4], or multiple different technologies, such as Zigbee, Z-Wave and ONVIF can work together [5-7].

HA systems generate large volumes of sensory data, even when the users are not interacting with the system. Additionally, user commands change states of actuating devices, and these changes can also be tracked. The information about the way users interact with the system can be of interest for further analysis because once it is properly operated, it can serve to improve the system itself, customer experience, as well as to users to have better insight in their system usage. This can lead to a more efficient smart home system and cost minimization.

Sandra Ivanović is with Faculty of Technical Sciences, University of Novi Sad, Serbia (e-mail: sandra.ivanovic@rt-rk.uns.ac.rs).

Neven Jović is with with the RT-RK Research Institute, Narodnog fronta 23a, 21000 Novi Sad, Serbia (e-mail: neven.jovic@rt-rk.com). .

Marija Antić is with Faculty of Technical Sciences, University of Novi Sad, Trg Dositeja Obradovića 6, 21000 Novi Sad, Serbia (e-mail: marija.antic@rt-rk.uns.ac.rs).

Istvan Papp is with the Oblo Living, Narodnog fronta 21a, 21000 Novi Sad, Serbia (e-mail: istvan.papp@obloliving.com).

Capturing and storing large volumes of IoT data is a challenging task, as the number of changes that should be tracked grows with the number of users and the number of devices they connect into their smart home. Typically, NoSQL databases are used to store IoT data [8], [9]. Data is aggregated and transformed periodically, in order to form batch views, tailored for particular applications. If needed, the difference between the last calculated batch view and current system state is calculated using real-time processing. Such architecture is called *lambda architecture* [10]. Although Cassandra or HDFS are usually the best choice for large scale data collection and processing systems, some of the research indicates that MongoDB can also be used in small or medium-sized solutions [11], [12].

In this paper, the focus is on user data acquisition, processing and storage for the purpose of the existing home automation system [5-7]. The goal is to build a cost-effective cloud module, which can store information about changes in HA system network (when devices are added to or removed from the HA system, or failures of devices happen), as well as track changes of particular sensors and actuators in the system. Since MongoDB is already used by the existing system's cloud, data collection modules will also use this database as the primary data storage.

First, the architecture of the existing HA system is presented, and it is explained how changes of device states are reported to HA cloud. Then, the implemented data collection cloud modules are described. Finally, the performance of the solution is analyzed, in order to determine its limitations.

II. HA System architecture

In this section, the architecture of the target HA system is described, the way devices are represented in the system, as well as the way system components communicate with each other.

Architecture of the system is presented in Fig. 1. HA gateway connects end devices using Zigbee, Z-Wave, IP and ONVIF protocols. All devices are controlled by the HA gateway, which is acting as the controller/coordinator of different PAN networks. HA gateway is connected to HA cloud, in order to provide remote control of the system using mobile client applications. In addition to remote control, HA cloud provides user management and system administration services, alarm notifications, voice control, etc. Components of the system communicate using MQTT protocol [13].

HA gateway provides an abstraction layer, allowing for all devices to be represented in the same way within the system,

regardless of their underlying communication technology [5], [6]. Every device is represented by the list of supported services and service properties. Value of each property reflects the physical state of the device (light on/off, dim level, current temperature, etc.). Devices report changes of their physical properties to the HA gateway, using the appropriate IoT communication protocol (Zigbee, Z-Wave). The HA gateway maps every change to the device representation in the HA system, and informs other components of the HA system about the changes. To distribute information about device property changes, MQTT protocol is used. Gateway publishes the information about property change to the *event* topic.

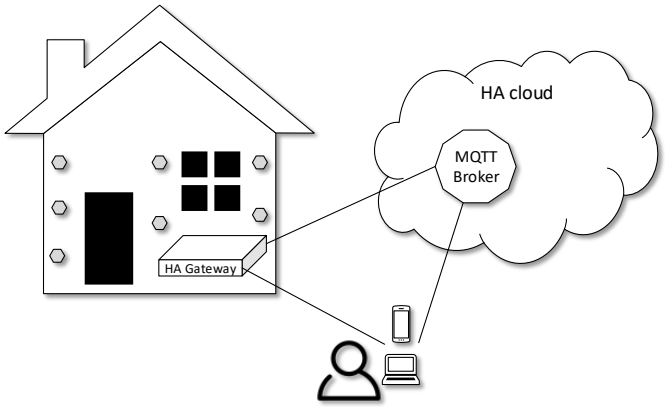

Figure 1 - Home automation system architecture overview

MQTT messages published to the *event* topic contain information about the ID of the device in the HA system, name and new value of the property that has changed, and name of the affected service – Table I.

TABLE I
DEVICE STATUS CHANGE EVENT PAYLOAD

Parameter Name	Description	Example
Device ID	Unique ID of the device within the system, assigned by the HA gateway.	12345
Service name	Name of the service	Alert Service
Property name	Name of the service property	Alert Start
Property value	Value of the property	True/False
Timestamp	Time when change happened	2019-04-03T09:52:08+02:00

III. Data Collection Service

In this section, details of the implementation of data collection module within HA cloud are presented. The main goal is to collect historical data about device property changes in the system. Additionally, for the purpose of network issues debugging, changes in the HA network are monitored, and snapshots of the local network topology are stored.

The architecture of the implemented data collection service is presented in Fig. 2. Device history sub-module monitors changes of physical device properties in the system. Network history sub-module is responsible for storing snapshots of network topology. In order to manage potential bursts of events reported by HA gateways in the system, all relevant MQTT messages are first queued using RabbitMQ [14], and then further processed, in order to store them in the appropriate MongoDB collection.

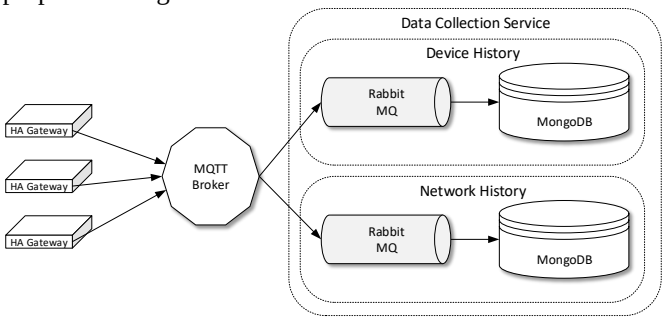

Figure 2 – Data collection service architecture

A. *Device History*

Device history module is subscribed to MQTT messages (events) reporting device state changes. As already said, device change event message contains information about the ID of the device, and modified property of some service. Depending on the service and property in question, data is stored in dedicated MongoDB collection.

All data is aggregated by the hour, i.e. every entry in the database contains the list of changes for one particular device ID, during one hour. This data is available for users to see in the web client application, once they log in into their account. Also, for some of devices, such as plugs, current state can be monitored in real-time. Graphs are shown in Fig. 3, Fig. 4 and Fig. 5.

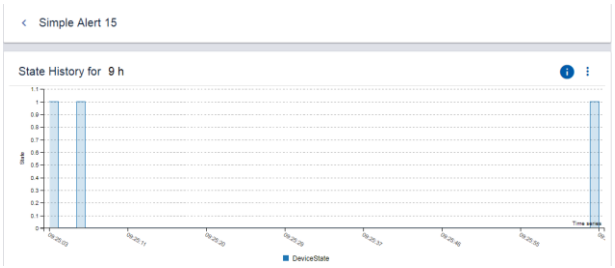

Figure 3 - Node history for the last hour

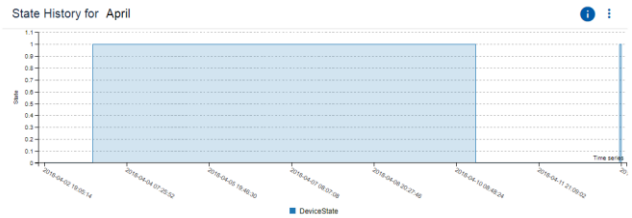

Figure 4 - Node history for the last month

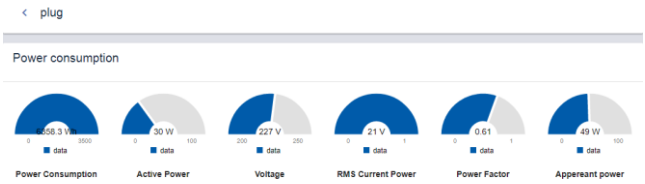

Figure 5 – Real-time changes

B. Network History

Network history sub-module provides an overview of local mesh network and device routing. This information is of particular interest for debugging purposes, if there are issues in device connectivity. Network history listens to events announcing devices that are added or removed from the system. These events cause network topology changes, which are referred to as *major changes*. Whenever a major change occurs, network history module requests detailed information about network topology from HA gateway, and stores it as a snapshot in the database. Users can browse through snapshots, as presented in Fig. 6 and Fig. 7.

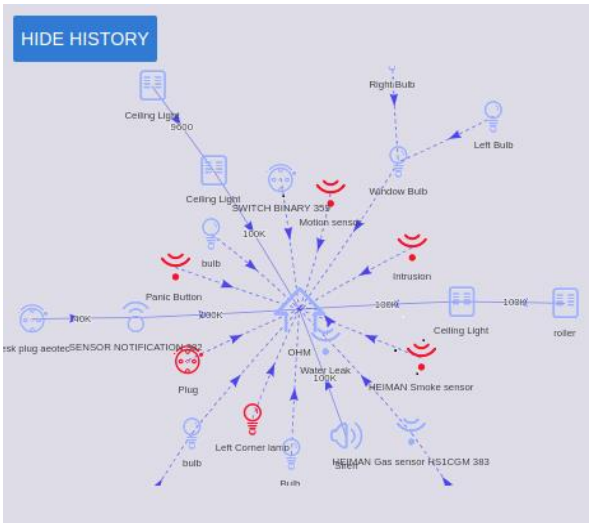

Figure 6 - Network history graph

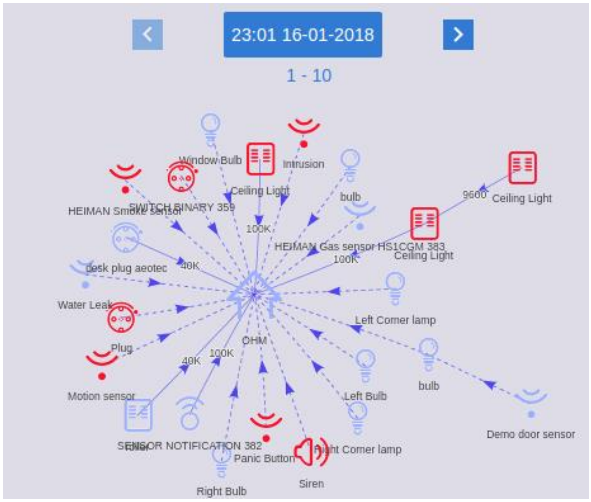

Figure 7 - Network history graph changes

IV. System Performance

In order to test the performances of the data collection module, we monitored consume time and number of messages in a queue. For the testing purposes, a lot of events had to be sent in a relatively short time period. Since it was not realistic to use real consumer data to perform these tests, we had to accomplish this by using virtual HA gateway models. Virtual HA gateway models are created solely for system testing. They are written in NodeJS and fully configurable. Virtual gateways can connect to cloud MQTT broker and generate asynchronous events, reporting the changes in the system. Parameters in the performed tests were the same for the each test. Configured values were:

- Number of virtual gateway models
- Number of different or same devices per model
- Frequency of device property change

HA virtual gateways support the MQTT communication, as well as the real one, and all the other feature that the HA gateway has. Regarding the HA Cloud architecture, it is consisted of two processor cores virtual machines, with 2 GB RAM Memory. Each service within the HA cloud setup is duplicated and event load balancing was implemented in a master slave manner. In case of an error, only one instance is affected, while the other one remains running. To improve system efficiency, database and MQRabbit are separated as virtual machines as well. Total number of the machines is 23.

As virtualization environment, ProxMox platform was used [15]. ProxMox is an open source solution for virtual server management, based on QEMU/KVM and LXC technology. It enabled us to cluster the machines, handle the instances and connection between them. Separating the micro services and scheduling them across various machines was done based on their load. Since node history is very highly loaded, it is an instance of its own. Setup architecture overview is given in the Figure 8.

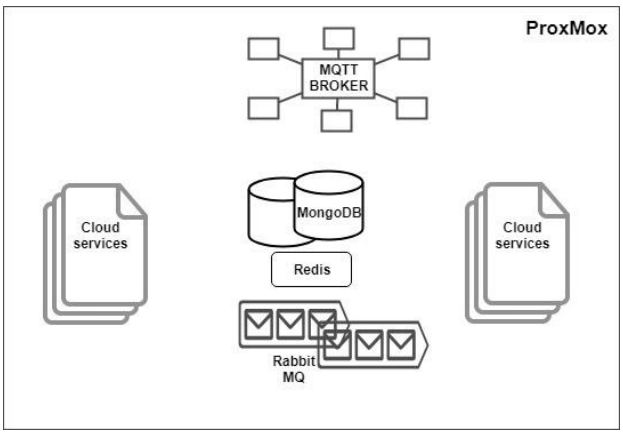

Figure 8 - ProxMox architecture overview

Total number of virtual HA gateways in setup was 600. Each one had around 30 devices.

RabbitMQ performance

When performing load tests, we monitored RabbitMQ queues, in order to detect potential limits in event load and processing. For each instance of Node History it was possible to vary the number of queues. The other variable parameter was the prefetch size. Consumer prefetch number is limit number of unacknowledged messages per channel / customer.

Firstly, we observed CPU on broker. On Figure 9 and Figure 10, we see CPU load when no events from virtual gateways had been fired. From the moment events started, we can see CPU load went above 80 percent. On Figure 11 we can see message rate in queue.

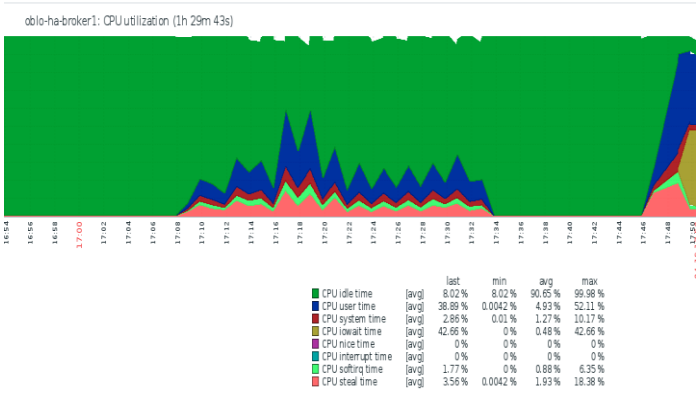

Figure 9 – CPU load

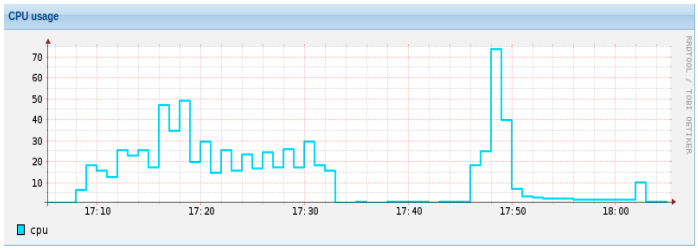

Figure 10 - CPU load graph

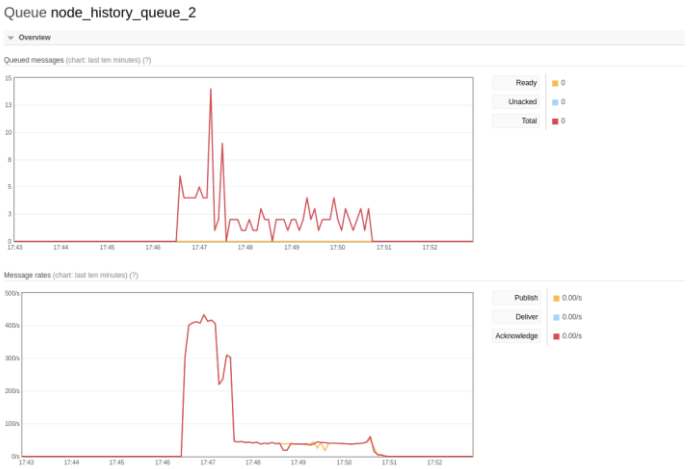

Figure 11 - RabbitMQ queue state

Secondly, we observed RabbitMQ queues and consume / publish ratio. Monitoring was done in RabbitMQ Console.

1. In the first scenario, number of queues was one, with prefetch parameter set to one as well. In Figure 12 we see that number of messages in queue went from 0 to around 60 000 in about five minutes. Also, on the lower graph we see that, in this case, consume is about 50% slower than publish rate. Therefore, this hasn't proven to be the optimum solution.

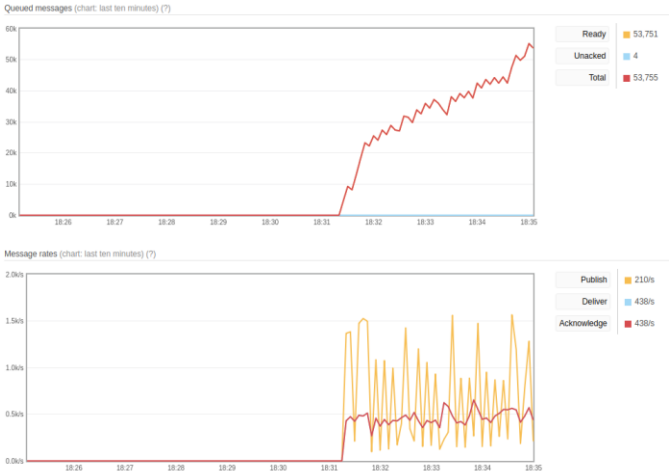

Figure 12 - One queue with prefetch parameter set to one

2. In the second scenario, number of queues was still one, with prefetch parameter set to 90. In Figure 13 we see that consume and publish rate are nearly the same, with publish being a little bit higher. Also, there are a few peaks of published messages in queue. Still, this result is much better than the previous one.

Figure 13 - One queue with prefetch parameter set to 90

3. In third scenario we tried having two queues, with prefetch parameter set to one again. In this case, we can see on Figure 14 that there was a publish peek at first that lasted for about 30 seconds, after which publish and consume rate mostly stabilized, but still publishing was faster than consuming. Graph from other queue, shown on Figure 15, show us that publish and consume rate were in fairly the same ratio as in the first queue.

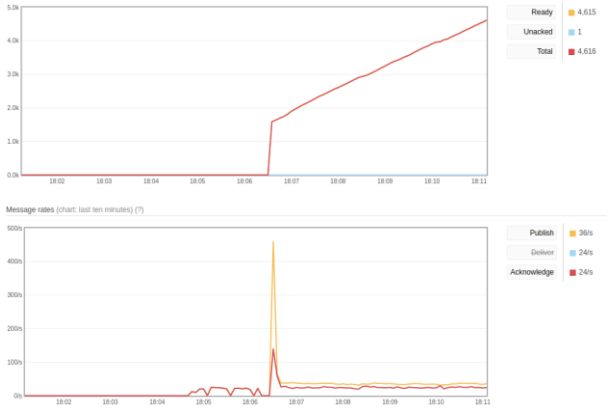

Figure 14 - Two queues with prefetch parameter set to one - First queue

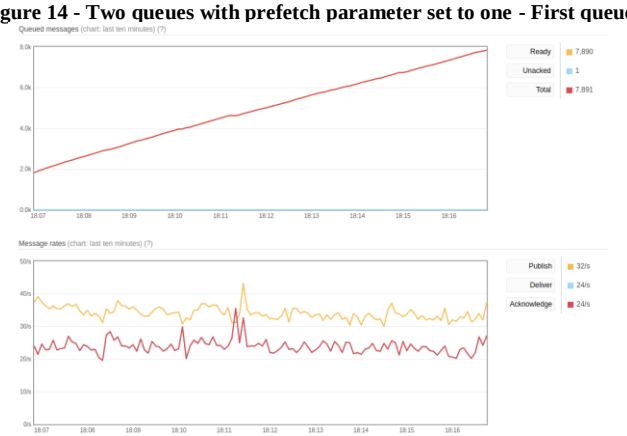

Figure 15 - Two queues with prefetch parameter set to one - Second queue

4. Fourth scenario was setting up two queues with prefetch parameter set to 90. This has proven to be the ideal case, since, as we can see on Figure 16, publish and consume rate are the same. There was only one short peak at the begging of publishing, but after that, queue was low on messages, since they were immediately consumed.

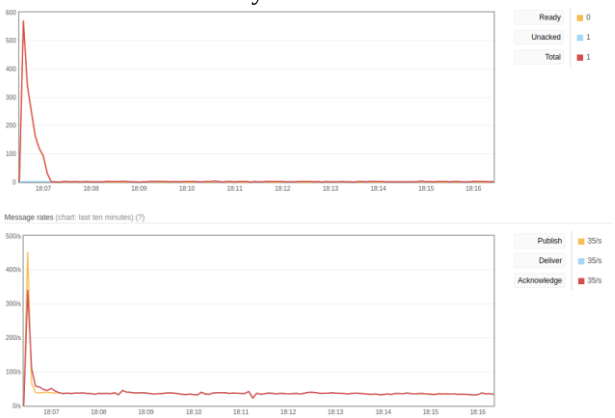

Figure 16 - Two queues with prefetch parameter set to 90

V. Conclusion

One implementation of the data collection service was presented, which is based only on the technologies that are already used in the existing HA cloud. Testing was done for the number of 600 gateway devices, simulated with virtual gateways. Event frequency was around 600 events per second. Variables in the testing process were number of queues as well as prefetch parameter. Results show us that rising the prefetch parameter improves consume rate massively.

Also, more queues help the balancing of the events, therefore we get better response time, but in combination with higher prefetch value it gives the best results.

Further tests will be done on a larger number of gateways and higher frequency rates. Also, we will test the system response times when MongoDB is replaced with Cassandra database. Another direction we would like to go for is replacing RabbitMQ with Kafka.

Using Online Weather Data to Improve Smart Home User Experience

Milica Matić, Milan Tucić, Marija Antić, Roman Pavlović

***Abstract* – In this paper we present one solution for integrating online geolocation and weather services with the existing smart home system. The goal is to improve smart home user experience, by enabling automatic system reaction to different astronomical data parameters (sunrise, sunset, moon phase), or changes in weather forecast. The existing smart home system is extended to hold information about user location, and to monitor online weather data for this location. Details of the implementation and communication between components of the system are presented and functional and load testing of the implemented service are evaluated.**

Index Terms – smart home; weather; geolocation; cloud; gateway

I. INTRODUCTION

The progress of computer and networking technologies has enabled the development of various smart devices, which can be controlled and monitored remotely. These devices are grouped into Internet of Things (IoT) networks in which they are communicating with each other, in order to convey status reports, network control messages and commands [1]. IoT technologies can be applied to both industrial and consumer use-cases. Smart home systems represent one of the growing areas of IoT consumer applications [2] – [4]. In smart home solutions, various devices (sensors and actuators) can connect to automate daily tasks in the household, and enable remote control and monitoring of the system by end users.

Typically, actions in the smart home system are executed by the user command from client application, but they can also be automated by a set of user-defined rules. Rule execution can be triggered at a certain time during the day, or as a reaction to values measured by some sensors in the system [5]. In this paper, we explore the possibility of extending smart home user experience by adding online weather data information to the system. Measurements of current sunlight and temperature have previously been used to control power consumption in smart homes, and effort has been made to design algorithms to control this process automatically [6] – [8]. However, in these scenarios user has no control over the actual algorithm implementation. The idea behind this work is to represent weather data in a form of a virtual "weather device", according to the unified device model in the existing smart home system [9]. This way, users can monitor current weather information, as well as set rules which use weather information as triggers. For example, the system can be set to turn off all lights after sunrise, or turn them on after sunset. The information about sunrise and sunset is retrieved from the online weather service, based on the smart home location. Also, the system can be set up in a way that allows notifications to be sent to users, whenever weather data changes. For example, user can be notified if it is raining outside or if the storm is close, and similar. Additional rules can be configured by the user, in order to protect the home from bad weather conditions, or setup heating or cooling depending on the outside temperature changes.

As already said, online weather data will be used in the existing smart home system. Therefore, the architecture of the target smart home system is first presented, and communication between system components is explained. Then, details of the integration with location and weather services are provided. Finally, functional and load testing of the newly implemented module is performed.

II. SMART HOME SYSTEM ARCHITECTURE

In this section, the architecture of the existing smart home system is briefly explained – Fig. 1.

The existing home automation system [5], [9] allows users to connect end devices (nodes) which use Zigbee, Z-Wave, ONVIF, and IP to communicate with each other. The central component of the system is the home automation gateway, which acts as a bridge between different IoT networks integrated into a system. It creates a level of abstraction, so that all nodes in the system are represented in the same way, by a set of their functionalities and characteristics [9]. This allows applying the same control logics to all of the nodes, while being agnostic of the actual communication protocol components are using. With this abstraction, gateway becomes bridge for communication between cloud and end devices, in the system [10].

User application allows user to manage and control their smart home system. They provide intuitive UI to all gateway functionalities allowing user fine-grade control over gateway while in the same time hiding complexities of underlying technologies.

Remote access to the system is provided by the home

Milica Matić is with Faculty of Technical Sciences, University of Novi Sad, Serbia (e-mail: milica.matic@rt-rk.uns.ac.rs).

Milan Tucić is with with Oblo Living, Narodnog fronta 21a, 21000 Novi Sad, Serbia (e-mail: milan.tucic@obloliving.com).

Marija Antić is with Faculty of Technical Sciences, University of Novi Sad, Trg Dositeja Obradovića 6, 21000 Novi Sad, Serbia (e-mail: marija.antic@rt-rk.uns.ac.rs).

Roman Pavlović is with Oblo Living, Narodnog fronta 21a, 21000 Novi Sad, Serbia (e-mail: roman.pavlovic@obloliving.com).

automation cloud, as well as a number of advanced features, such as voice control and integration with different third party services. Cloud has a micro-service architecture, i.e. it consists of multiple clearly decoupled services, each being in charge of different functionalities. For communication between different cloud micro-services HTTP protocol is used. Also, HTTP REST APIs are used to integrate with various third party services, such as video surveillance systems, voice control (Amazon Alexa, Google Home), etc.

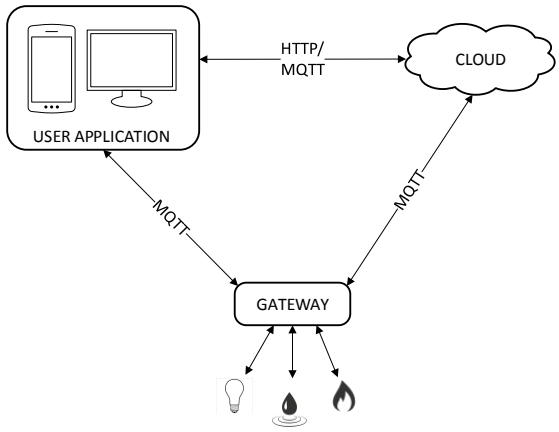

Fig. 1. Smart home system architecture

A. *Communication between smart home system components*

Main components of the home system communicate using MQTT (Message Queuing Telemetry Transport) protocol [11]. A universal messaging model is applied to all system components, i.e. the MQTT topic structure and payloads are defined on system level. MQTT broker defines topics that client is allowed to send messages on, based on the client type (gateway, application, or cloud micro-service).

There are three different message types exchanged between the system components:

1) Request messages – used to send commands or queries
2) Response messages – used to respond to requests
3) Event messages – used to asynchronously report changes in the system (device property changes, alarms, etc.)

In this paper, the communication between gateway and cloud is of interest. Topics that MQTT messages are published to contain information about the following:

- gateway id – unique gateway identifier
- user id – unique identifier of user connected to specific gateway
- service name – cloud service name that gateway is sending message to
- type – message type (request, response, event)

Regardless of their type, all MQTT messages contain the message ID and a variable number of parameters - TABLE 1.

TABLE 1
MQTT MESSAGE PAYLOAD

Field name	Required	Description
ID	yes	Unique message identifier
Parameters	no	Message parameters

The actual parameters depend on the message type. Common parameters for all request messages are listed in TABLE 2. Every request message contains information about its sender and type (defining if it's a command or a query), as well as the name of the message. Common parameters for all response messages are listed in TABLE 3. As a response to a command or query, status code is returned, which may be accompanied by additional information in the description. Finally, event messages must carry the event name, but there can also be additional information within the optional event fields - TABLE 4.

TABLE 2
REQUEST MESSAGE PARAMETERS

Field name	Required	Description
Sender	yes	Message sender
Type	yes	Message type (command or query)
Name	yes	Message name

TABLE 3
RESPONSE MESSAGE PARAMETERS

Field name	Required	Description
Code	yes	Is request processed successfully
Description	no	Additional information

TABLE 4
EVENT MESSAGE PARAMETERS

Field name	Required	Description
Name	yes	Event name

III. WEATHER AND GEOLOCATION INTEGRATION

In this chapter, the details of integration with third party geolocation and weather services are presented. On gateway side, the weather information is incorporated into a virtual weather device, while on cloud side two micro-services are implemented, which communicate with the selected geolocation and weather APIs. Gateway communication model is extended to support new cloud. User application is customized for a better user experience by allowing user to monitor information obtained from online weather service and to act upon it.

In Fig. 2, a high-level architecture of the solution is presented. First, during first time run and system setup, or when the home address is changed, geolocation micro-service within home automation cloud is notified by the application. This micro-service then maps the address provided by the user

to the location information (longitude and latitude) of the city the provided address belongs to. Location information is then used by the weather micro-service, as a parameter required by the third party weather service API, to fetch weather forecast and astronomical data for the location in question. Changes in weather data are reported to gateway and applications using MQTT event messages. In order to avoid frequent communication with third party weather service, information about current weather is cached in Redis [12]. Cached data is set to expire within a predefined period of time, and after this time has elapsed it will be automatically deleted from cache. Whenever a gateway requests information about weather in its location, the lookup in weather cache is first performed. If there is no entry in weather cache, the fresh weather data is fetched from the third party weather service, new entry in weather cache is formed, and all gateways in the same location are informed about new weather parameters.

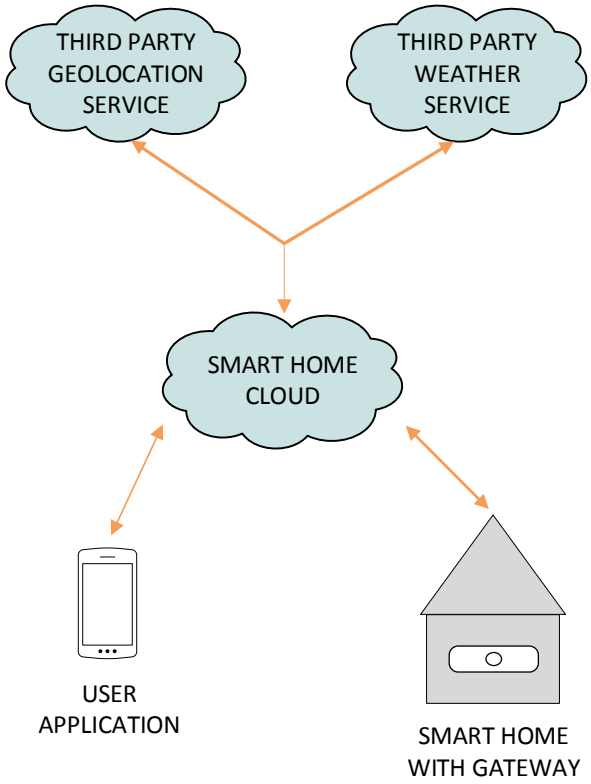

Fig. 2. High level system architecture

A. *Geolocation micro-service*

In order to be able to fetch relevant weather data from online weather service, home automation cloud has to be aware of the gateway location. Therefore, end user has to allow the smart home system to use their personal information, i.e. home address. There are different techniques to obtain location information:

1. GPS location – method used to detect exact position of the user's mobile device
2. Mobile cell information – using triangulation algorithm based on cell tower information where cell towers in exact locations are well known
3. WiFi network information – Internet services constantly update WiFi network information from routers all over the world. These services match GPS data and available WiFi networks information sent from mobile phones thus calculating precise location of each WiFi router
4. IP information – user's location is fetched based on the device IP address
5. Providing location via smart home application – user manually enters postal address of his household.

Techniques 1 to 4 are already used by mobile phones and browsers to estimate the location of the user during the home automation system setup. If the automatic estimation of the address is not precise enough, user can always provide the correct address manually, using the application.

Geolocation micro-service is in charge of mapping the provided address to the latitude and longitude. It communicates with third party online service in order to geocode the given address [13]. Once address is geocoded and latitude and longitude values are obtained from third party online service, unique identifier (location ID) representing specific location is created and stored in the database, containing information about the location it refers to. Since there is no need to request weather information for exact latitude and longitude of every household in the system, only city-level weather information is of interest. Therefore, all gateways in the same city are mapped to the same location ID, and information from the geolocation location ID entry in the database is afterwards used in communication with third party weather service. Also, once the gateway address is mapped to the location identifier, the gateway is notified about the assigned location ID, in order to correctly subscribe to the relevant weather information.

In case where user applications provide address information without user interference, usually they provide geolocation micro-service with latitude and longitude values. On condition that this data is provided to it, geolocation micro-service will do reverse geocoding [14] of provided data in order to save physical address to database. In this case, third party geolocation is called, as it is for geocoding purposes.

Figure Fig. 3 represents communication taken between home automation gateway, geolocation micro-service within home automation cloud and third party geolocation service in order to connect home automation gateway with physical address.

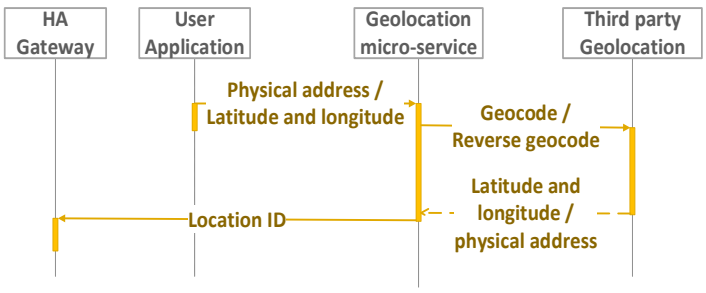

Fig. 3. Obtaining location information from third party geolocation service

B. *Weather micro-service and weather device*

When weather service is enabled for the particular gateway, information retrieved from it will be presented as properties of a virtual weather device. This virtual device is listed in the user application among other physical devices. Virtual weather device abstracts services and properties given in the TABLE 5.

TABLE 5
WEATHER DEVICE SERVICES

Service name	Description
Address	Physical address of the gateway
Astronomy time	Sunrise and sunset information
Location	Gateway latitude and longitude
Weather configuration	Weather data refresh interval
Weather	Weather information
Wind	Wind information

Users can configure how often weather information should be updated for their virtual device. After the specified time period, gateway will query the cloud for updated weather data.

Gateway asks cloud for new data in three cases:

1. Gateway has come online - if gateway was offline, first time it comes online, weather data should be checked
2. Gateway's location has changed – in case user has changed gateway's address, weather data has to be updated accordingly
3. Refresh period time has passed and data needs to be updated.

The communication between the gateway, weather micro-service, weather cache and third party weather service is depicted in Fig. 4.

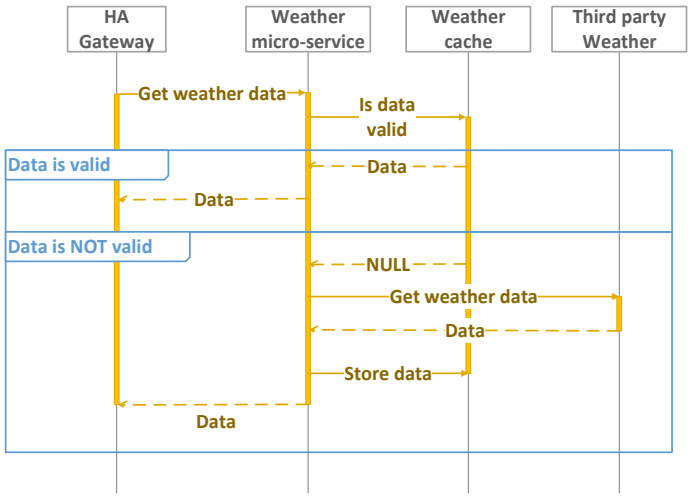

Fig. 4. Obtaining weather information from third party weather service

Gateway sends MQTT request to home automation cloud, to fetch new weather data. Cloud first checks the weather cache for information. If cached data is valid, cloud will fetch data from cache and send it to the gateway as a response message. However, if data in cache is not valid, cloud has to contact third party online weather service to fetch new data. Once data is obtained from the third party weather service, response is sent to gateway. In order to minimize the number of query requests sent by gateways in the same location, notification by MQTT event messages is added. Hence, after sending the response to the gateway which asked for updated weather information, cloud will notify all gateways in the same location, by sending them updated weather data in an MQTT event message.

Whenever a new location (location for which weather data was not obtained before) is added to the system, weather information has to be obtained for it. New location is saved to the database with location ID created by geolocation micro-service. Then, weather micro-service will fetch data from online weather service and store this information in the weather cache.

C. *Messaging model extension*

In order to support new geolocation and weather service functionalities, MQTT messaging model had to be extended to support new topics and messages.

New topic was added to allow communication between gateways and geolocation micro-service. It is used for providing information about new postal address of the gateway. Also, two new topic groups are added for communication between gateways and weather micro-service. One topic group is used for direct communication between one specific gateway and the cloud, in cases when the gateway requests weather data and cloud sends response to it. Second topic group is used for cloud to send events about weather data changes to groups of gateways in the same location. For every location, a new topic is formed.

IV. EXPERIMENTAL EVALUATION

In order to fully test provided solution, we had to use gateways located in different world areas. This was done by using virtual gateway model. Virtual gateway model is a software gateway model created for purpose of system testing. It is implemented in NodeJS and can be configured to support various end devices and rules. Software model can be assigned to a user in the system, same as the physical gateway. After linking the user profile with the virtual model of the gateway, user is able to control it in the similar way as he would control real physical device. Virtual gateway model supports communication using MQTT protocol, as well. Existing model is extended to support geolocation and weather services and to test communication between cloud and gateway. Various locations were added to the system, and cloud was tested for obtaining data for proper locations and serving it to the proper gateways.

Home automation cloud architecture is presented on the Fig. 5. Every block in the figure represents one virtual machine with two processor cores and 2 GB of RAM memory. These virtual machines are part of ProxMox virtual environment [15]. Geolocation micro-service is located in one of three machines with home automation micro-services. As figure shows, geolocation micro-service and Redis database

are placed in separate virtual machines which reduce the load on the individual machine.

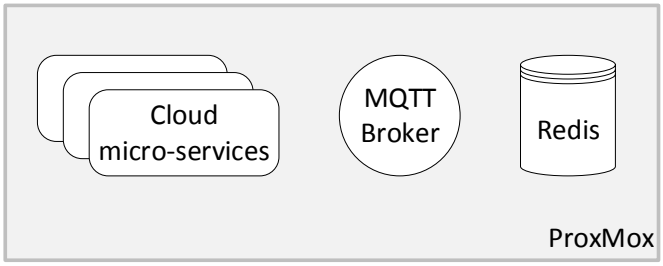

Fig. 5. Home automation cloud architecture

First, we test the performance of Redis weather cache, depending on the number of different location IDs in the system. We observe memory consumption and response times when gateway requests information, as well as CPU load on Redis instance.

Further, we vary the frequency of weather data update on the gateways, in order to determine its impact on the system performance.

For testing purposes 4000 virtual gateways, all located in different locations, were configured to obtain weather data in the same time. Weather cache was cleared before tests were started. Additionally, we tested system where 4000 virtual devices were located in the same location, but frequency of weather data update was changing.

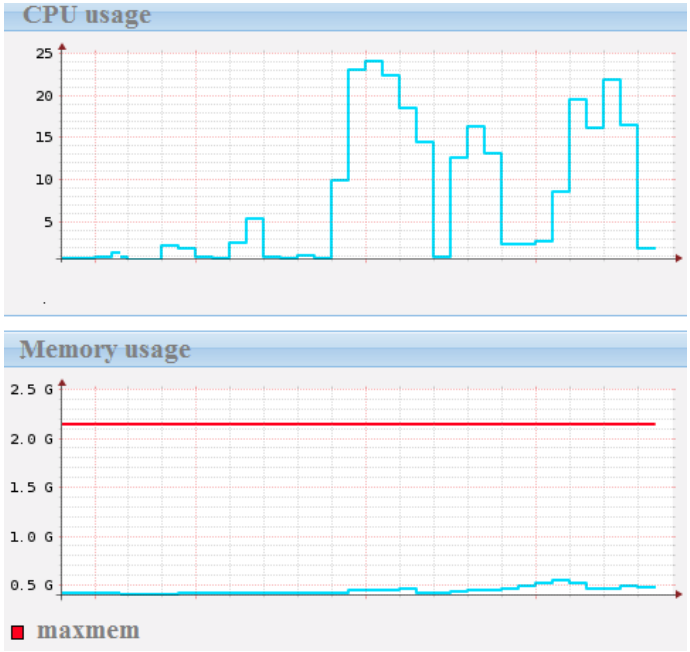

Fig. 6 Average CPU and memory usages on Redis machine

Average tests results are depicted in Fig. 6. Results show that CPU usage does not exceed the value of 20%, and memory consumption is beneath 1 GB after 8000 different weather information is stored in Redis.

Finally, we test the end-to-end performance when using real physical gateway and third party geolocation and weather services. Results are presented in the TABLE 6. Typically, it takes 910,89 ms to map the address to the location ID if data is obtained from online third party service, apropos 39,43 ms if data is gathered from database. Fetching weather data from weather cache requires 14,45 ms, on average. However, if data is obtained from online third party weather service, it takes 222,11 ms to get the data, on average.

TABLE 6
EXPERIMENTAL RESULTS

Test case	Average time in ms
Get existing location ID from database	39,43
Get location from third party online service	910,89
Get weather data from cache	14,45
Get weather data from third party online service	222,11

V. CONCLUSION

One approach to using weather data within the smart home system was presented. This approach enables users to monitor weather information for their household location, as well as set automatic rules that can be executed if weather or astronomical data changes in some way of interest. Future work will be focused on better location analysis, as bigger cities can have multiple localities, and obtaining weather data for these localities could provide better and more accurate results.

Industrial Fog Computing Platform and System Testing Through GUI

Rade Tišma, Ivan Velikić and Velibor Mihić, *Member, IEEE*

***Abstract*—Fog Computing is next step in supporting industrial IoT. It offers solutions for harsh demands in modern industrial environment. Manipulation with enormous data generated on daily level in industry and enabled almost real time analysis with safeness always on mind, is supported by Fog Computing model. This paper shortly presents industrial IoT platform based on Fog Computing architecture. Basic functionality of available GUI components is described with some quick turn on system testing through available interfaces for users.**

***Keywords*—Fog Computing, Edge Computing, Industrial Internet of Things, Cloud Computing.**

I. Introduction

In the world of industry (machines, sensors and actuators), which is connected on different levels and strives to be even more connected, integrated to look like one automated system, and where need for flexible structure emerges to support incoming rapid business demands, Fog Computing comes to scene to offer a solution. Fog Computing (or Edge Computing, also commonly used synonym), term firstly used by Cisco company, shifts storing and processing power to the edge of network, close to source [2]. The massive amount of data that industrial IoT (*Internet of Things*) devices are generating presents problem for exclusive use of cloud computing model [2]. Cloud architecture relies on internet links and their throughput is the bottleneck for IoT traffic. Also, internet links are unstable and variable. Transferring a lot of data is not the only biggest challenge for industrial IoT, real time response is also very important factor. Real time reaction, system reaction in real time based on data accessible in milliseconds (analysed in almost real time) is imperative for modern industrial systems. The security of sensitive data can be on highest level simply because there is no need to distribute all data over internet [1]. Only partial data can be sent over internet (in raw form or analysed), which is useful for high level analysis. Openness of this model allows user to choose, between other things, which data are going to be sent and in what form. An implementation of Fog Computing architecture, Nerve platform [3], provides openness when it comes to connectivity with multiple IoT cloud solutions by using protocols AMQP, MQTT, REST/JSON and OPC UA. Beside capability to integrate with existing infrastructure of user, there is also ability to connect with internal cloud-based component called fogSM (*Fog System Manager*) [3]. FogSM is central component that manages fogNodes (edge devices) and underlying applications. FogNode [3] is a network edge device that combines the capabilities of a computer system, network system and storage system in purpose-built hardware for full life cycle management of IoT edge devices. It hosts both real time and non-real time applications on the same node. FogOS (*Fog Operating System*) [3] is software stack that runs on fogNode, based on CentoOS Linux distribution.

Rade Tišma is with RT-RK Institute for Computer Based Systems, Jovana Dučića 23A, 78000 Banjaluka, Bosnia and Herzegovina (e-mail: rade.tisma@rt-rk.com).

Ivan Velikić is with the RT-RK Institute for Computer Based Systems, University of Novi Sad, Narodnog Fronta 23, 21000 Novi Sad, Serbia (e-mail: ivan.velikic@rt-rk.com).

Velibor Mihić is with the RT-RK Institute for Computer Based Systems, University of Novi Sad, Narodnog Fronta 23, 21000 Novi Sad, Serbia (e-mail: velibor.mihic@rt-rk.com).

II. FogOS – Software Stack

FogOS is software stack based on CentOS Linux distribution that supports secure virtualization of Linux and Windows based virtual machines, Docker container environment management, Windows application hosting (within Windows virtual machines), and open interfaces for fieldbus device communication. FogOS provides complete fog computing solutions along with fogSM. CentOS serves only to support all other applications and services that are part of Nerve software and rely on it. Most important thing that CentOS supports is integrated virtual machine – adminvm. FogSM is part of fogOS and it represents cloud-based component for managing fogNodes and applications on them [3]. FogOS enables storing, visualization and processing of collected data using customized open source and proprietary software. KVM (*Kernel-based Virtual Machine*) hypervisor (part of fogOS) runs VM (*Virtual Machines*) in real time, with user software, and allows user to integrate existing software into Fog Computing platform. Figure 1. illustrates virtual machines deployed on fogNode by user and real time OS.

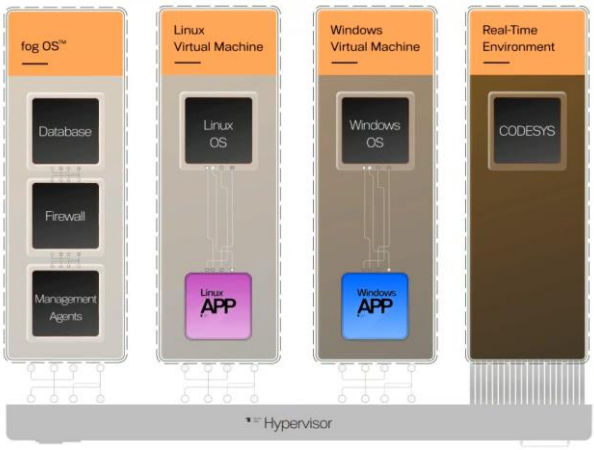

Fig. 1. Users virtual machines and Real Time OS with Codesys.

For the system users on the local level (near to a fogNode) there is a local UI (*User Interface*). Local web server allows users to interact through local UI with fogNode. To host a web server and to manage Docker containers (deployed by user) an integrated virtual machine (adminvm) is used. Local UI provides network related settings for fogNode, fogSM connection settings (IP address field), user password changing, and displaying some information for running system such as: CPU usage, RAM usage, IP address, software version, etc. Analysis and visualisation of gathered data is available with Grafana [4] – a general purpose dashboard and graph composer, which runs as a web application [3]. The collected data are stored locally using open source TSDB (*Time Series Databases*) – influxDB [5]. At the same time, it is possible to send data to fogSM, where the user can view data in different forms. Figure 2. shows WAN interface settings.

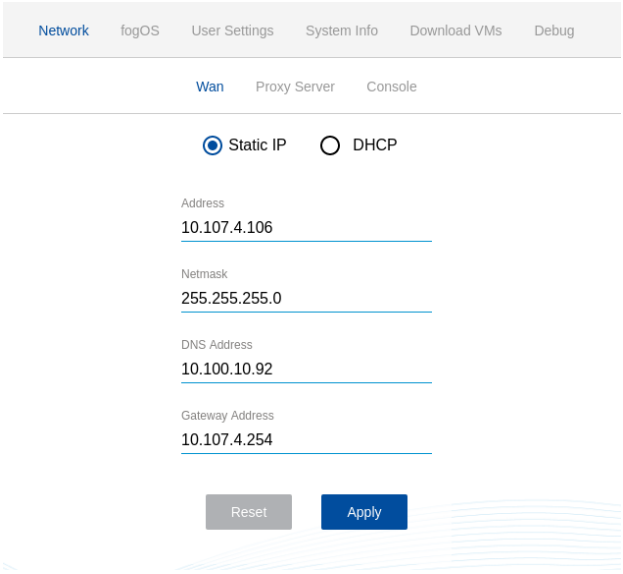

Fig. 2. Wan interface settings for local UI.

System testing of local UI can't be done using only interface itself. Testing certain functionality requires doing checkups on underlying system by using CLI (*Command Line Interface*) tools. Changing network configuration in local UI can be verified with CLI tools on the system, like ip utility tool. The Local UI also provides feature to download raw VM images and image definition file of a virtual machine from the fogNode to the development machine. This feature supports scenarios where a VM is locally modified by the user and then stored, either to be rolled out to other fogNodes or to be used as backup. Testing VM download on local UI requires background check on the system. For this purpose qemu-img tool [6] is used to verify downloaded images. Local UI provides a few features more. It gives a user ability to configure network interfaces according to internal network structure, to download changed VMs (for backup purpose or distribution). Also it allows setting connection with cloud component and getting some system information that can be very useful to the end user.

III. FOGSM - SYSTEM MANAGER

FogSM is embedded cloud-based component of fogOS that manages fogNodes, application provisioning, and deploying over cloud portal. It can be deployed on commercial cloud services such as AWS (*Amazon Web Services*) and Azure. Or at customer's premise server. In both cases it's necessary to have fully qualified hostname of the fogSM instance to connect to the cloud portal. Figure 3. shows fogSM cloud portal interface.

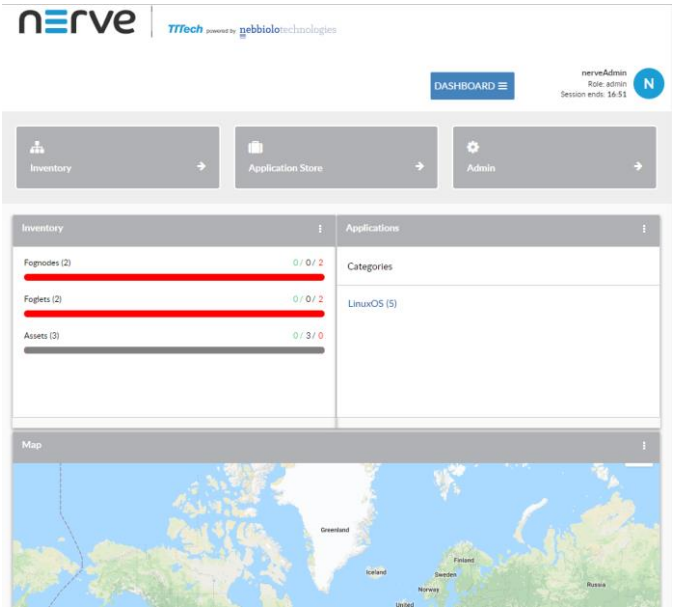

Fig. 3. Home page of fogSM portal interface.

Interface menu offers user management – RBAC (*Role Based Access Control*), fogNode management, and

application management. Main menu consists the following six items:

A) Dashboard
B) Inventory
C) Config Store
D) Application Store
E) Datastream
F) User

A. Dashboard

Dashboard is the default view for logged user. It gives a quick overview of currently connected fogNodes, notifications for user actions, provisioned applications, and geographical location of fogNodes on map.
Testing dashboard is pretty much straightforward because it requires testing correctness of links to specific page (e.g. Inventory) and comparison of data with data on particular page.

B. Inventory

Inventory page allows users to manage fogNodes and software on them. Opening this page reveals topology browser that hierarchically organize the devices (fogNode, assets, virtual assets, software components, virtual machines, containers). Selecting any topology node provides information that is applicable to that node and its children (descendants) [3]. Information that is displayed is node type dependent. Basic info for each node consists of connection status, version information and network related information. It's also possible to see system information such as CPU type, amount of free RAM, storage capacity and network interfaces (drivers in use). Grafana [4] allows users to view data collected on the particular fogNode through fogSM database. User can create, edit, move and delete nodes. The different topology nodes in the hierarchy are arbitrary and user defined to enable customization of device organization. Each fogNode has its own ID, in order to be uniquely identified on fogSM. When it comes to testing inventory functionality it is mostly based on using interface itself. Only for testing topology tree regeneration (e.g. removing fogNode from it) and getting it back after restarting fogNode, it's necessary to read fogNode ID directly from the system (using CLI tool like cat) in order to check presence of reattached fogNode that was previously removed.

C. Config Store

It allows users to store application configurations. The configs can be a text-based config files such as json, xml, yaml etc or it could be a binary config files. The configurations can be added or deleted from the config store. Each config is identified by a unique key. Once the config item is created, it can be applied to a Docker or a Windows application [3]. Configs can be added or deleted from the CONFIG STORE section. For a text configs, appropriate type such as json, yaml can be selected to enable syntax highlighting. For testing applied config files it is necessary to check Windows or Docker application on fogNode.

D. Application Store

Application hosting feature provides the function of on-boarding applications into the application store and then deploying them on the fogNodes. Application hosting comprises of an application store and an associated set of operations, which are application on-boarding, application authorization, application deployment, application policy management, and Role Based Access Control management [3]. Different application categories are used to scope the list of applications currently available for deployment. Application categories are used to group a set of related applications.
Testing application store functionality, to be more specific, application deployment, demands verification on fogNode. For everything else, interface itself is sufficient.

E. Datastream

Datastream offers to user ability to create different stream pipes with analysis tools using simple intuitive drag&drop technique for stream pipe creation. User can save, edit and delete created stream pipe. Deployment of created&saved pipe is not restricted to fogSM, it can be deployed on any connected fogNode. Grafana is used for testing created data streams, both on fogSM and fogNode.

F. User

User page gives access to notifications (for each user action there is response from system - notification), information for system version, RBAC management (role creation or editing, operation and resource managing, user bindings) and for administrator account user and tenant management. User page also provides some system related settings, like allowing user to choose between Google Map or Open Street Map use for fogNode location. Some under development features can be enabled (for testing purpose) and a few minor things. Testing user page functionality is mainly done over existing interface because there are no fogNode related settings or anything else that involves communication with fogNode.

IV. Conclusion

Nerve (Fog Computing) platform for industrial IoT is complex software stack that includes a lot of customized or configured open source solutions chained to work together. GUI (*Graphical User Interface*) components offer good interaction with underlying system and allows user to have better insight of entire working process. Openness is a key factor for integration into existing software environment and at the same time it's biggest strength for this Fog Computing implementation. Comparing Nerve to other solutions is not very easy task. For each platform there is another approach and also different set of protocols that are used to leverage specific hardware – i.e. gateway. Most of platforms are built with specific hardware and that is not the case with Nerve. Nerve comes with purpose built hardware (fogNode) but it's designed to be hardware independent Fog Computing platform. Connection to several higher-level systems (clouds) via different protocols (if not available in the base product, the

function is easily expandable) and integrated Codesys, which enables accessing data, as well as taking over the control, are features that are not present on another platforms - at least not in most of them. Another thing that differentiate Nerve from other similar platforms is installation of additional applications (Docker and Windows) and virtual machines specific for particular customer.

When it comes to system testing through available GUI components it brings chalenges in entire process. Since GUI components are web applications (fogSM and local UI) it's natural to automate them using Selenim and Selenium bindings for Pyhon, Java, Javascript or other suitable programming language. Difference in automating tests for usual web applications and Nerve components (fogSM and local UI) is in existing hardware that is mostly managed through GUI. So, additional checks are required in order to get valid test results. Formerly means that operation or action taken in GUI, in majority of test cases, needs to be validated on fogNode (on CentOS host or adminvm) using some of Linux CLI tools available on distribution. This is one of main reasons why running automated system test suite takes so much time, and sometimes implementing particular automated test case can be really chalenging.

One solution of vehicle control software based on camera in ROS environment

Maksim Egelja, Nikola Teslić, *Member, IEEE, Research Institute RT-RK,*

Nemanja Lukić, *Member, IEEE, Faculty of Technical Sciences, University of Novi Sad,*

Zvonimir Kaprocki, *Research Institute RT-RK Osijek,*

***Abstract*—Software in automotive industry today is a very popular branch and brings many new challenges to the world of engineering. Recently, autonomous driving became one of the biggest challenges of this field. Goal is to develop a system capable of controlling vehicle almost completely independently.**

Work presented in this paper defines several modern autonomous driving algorithms and simulate them on modern platform. These algorithms are working with sensors attached to vehicle, such as camera, radar, lidar, etc. and include functionalities such as keep lane, controlling vehicle when "Stop" sign is detected and adapting vehicle speed when speed limit sign occurs in front of camera sensor.

***Index terms*—Autonomous driving; ROS; vehicle control based on camera**

I. Introduction

Recently, autonomous driving became one of the most popular software industry branches since engineers are working on providing highly automated driving systems, while over the past few years more focus is given on providing driving assistance. There are five levels of autonomous driving defined by experts and each of them describes the extent to which a car takes over tasks and responsibilities from its driver, and how a car and driver interact. Short explanation of each autonomy level is presented below.

Level 1 - Driver Assistance: systems on this level only support the driver, they do not take any control of the vehicle.

Level 2 - Partly Automated Driving: vehicle can control itself but driver remains responsible for control.

Level 3 - Highly Automated Driving: autonomous systems are taking control for the extended periods of time under certain conditions.

Level 4 - Fully Automated Driving: complete control of the vehicle by the system. Driver must remain able to drive.

Level 5 - Full Automation: completely autonomous driving, people are passengers only.

Vehicle needs many sensors due to its capability of sensing nearby environment. In figure 1 there is an illustration of most used sensors and their field of detection in autonomous car.

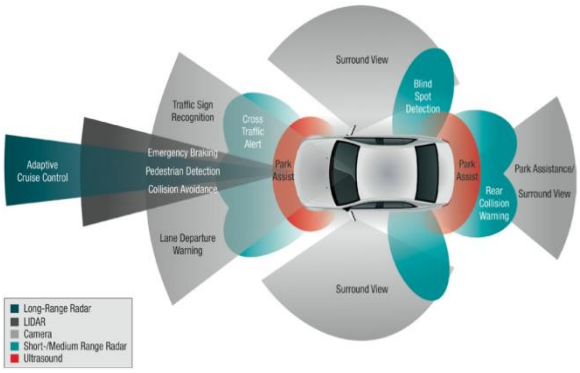

Fig. 1. Autonomous car with sensors

Today, there are commercial vehicles with integrated systems of autonomy levels 1 and 2. Further levels are bringing more challenges to the world of engineering. Due to the fact that there are many sensors attached to the vehicle such as lidar, full range and short range radars, multiple camera, ultra sonic sensors, there is a lot of data to collect and process in real time. Having this in mind engineers need huge computing power, special hardware units with very powerful processors, which are able to execute very complex algorithms. These include functionalities such as: trajectory planning, path finding, object fusion, etc, and they are mostly based on machine learning and neural networks.

Most components such as image processing, which are used for autonomous driving, are already solved as individual problems. Those components are highly important for this engineering field, but fusion of them still needs to be defined, in order to construct fully automated vehicle. In order to achieve this goal, engineers need to combine a great deal of research from different areas to produce highly automated vehicle pilot. Paper presents definition, implementation and

integration of such autonomous driving algorithms in simulated environment.

The rest of material is organized as follows. At the beginning, section II describes software libraries and platform used in this research, while section III describes system architecture, where its sub sections present more detailed description of each system block. Section IV gives the experimental results of this work, whereas section V presents a conclusion of the demonstrated work and proposes some of its possible future improvements.

II. Platform and Software Libraries

Goal of this work was to simulate real part of an autonomous driving system. ROS [1] (Robot Operating System) was used to simulate independent hardware units such as camera sensor or system control unit. Today, ROS is a very popular software system used for robot control, where the self driving vehicle can be defined as robot. Hardware units are simulated using ROS nodes where nodes are processes that are completely independent and can communicate with each other through specified topics.

Other part of this investigation was the OpenCV [2] (Open Computer Vision) library. All of the image processing was done using this open source library while complete work was realized using modern C++ programming language. Finally, units of this work are verified and tested using *gtest* [3] framework.

III. System Architecture

As explained before, ROS nodes were used to simulate hardware units in autonomous driving system. Schematic view of the system is shown in figure below.

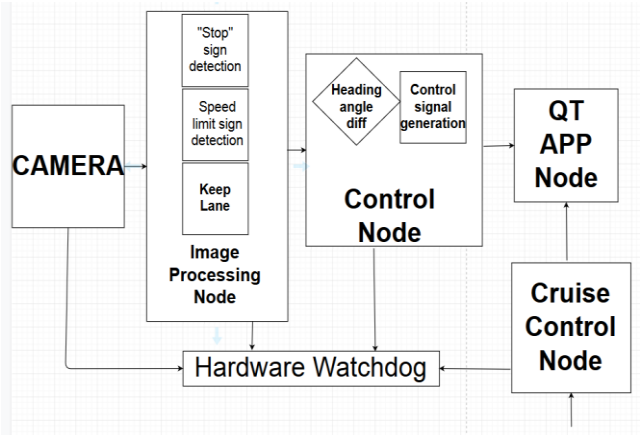

Fig. 2. Illustration of simulated hardware and signals between them

Camera node simulates camera sensor data and it sends raw pictures to image processing node. Due to the fact that camera needs to be calibrated, the reason why and the exact process of camera calibration is described in section III.A. Image processing node is in charge of all image processing algorithms in the system. It uses HAAR [4] feature based cascade classifier, which will be described in one of the following sections. It also communicates with camera sensor and control unit. Control node represents control unit of an autonomous driving system in a car. It can communicate with image processing and QT [5] application nodes. At the end, QT application node represents car's brakes, steering wheel and acceleration control units. It is possible to see how these systems work though GUI (Graphic User Interface). Besides recently mentioned nodes, there is a cruise control node which is in charge of collecting wanted speed data from the driver. There is a node that simulates hardware watch dog as well. This unit is capable of shutting down the whole system if something goes wrong. In further text, more detailed explanation of each node is given.

A. *Camera calibration process*

Camera needs to be calibrated due to measuring the size of an object in world units such as centimeters, or determine the location of camera in the scene. Camera calibration needs to be done since, according to this research, distance to "Stop" sign needs to be determined in order to properly stop the vehicle.

Today, in automotive industry, the most commonly used camera sensors are pinhole cameras. Pinhole camera model assumes that there is no lens in front of camera sensor and no distortion can occur in ideal case. In real world, there is a lens which introduces two types of distortion: radial and tangential. Radial occurs because of different lens thickness around the edges while tangential occurs because lens and camera sensor itself are not perfectly parallel. In order to remove all the image imperfections caused by lens and camera sensor, calibration is performed, which covers intrinsic and extrinsic camera parameters. Parameters are determined using matrix arithmetic and DTL (Direct Linear Transformation).

OpenCV currently supports three types of patterns used for camera calibration

- Classical black-white chessboard
- Symmetrical circle pattern
- Asymmetrical circle pattern

In this investigation, classical black-white chessboard pattern is used to calibrate the camera. For most of the patterns two snapshots are sufficient, while circular requires more snapshots in order to successfully calibrate the camera.

B. *Haar feature-based cascade classifier*

HAAR cascade classifier is machine learning based approach, where a cascade function is trained using many positive and negative samples. It is then used to detect particular objects in various images. This technique needs to extract features from the input images which are defined as value obtained by subtracting sum of pixels under black rectangle.

In order to calculate all needed features by using possible sizes and positions of kernels, big amount of calculation needs to be done in real time. In order to increase performance, HAAR introduces an integral picture, which uses an operation involving only surrounding four pixels for each pixel processed. Few types of features are shown in picture below.

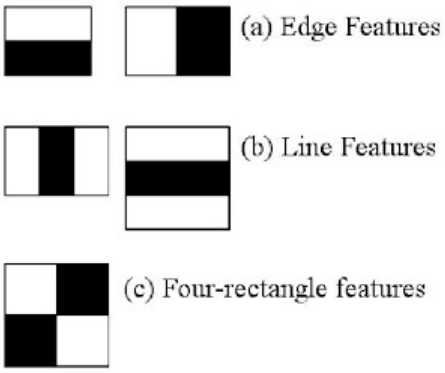

Fig. 3. Illustration of HAAR features used in cascade classifiers

C. *Image processing node*

This node firstly crops the image received from camera, and then extracts ROI (Region Of Interest). After cropping, frame is transferred to three HAAR feature-based cascade classifiers, trained for detecting "Stop" and speed limit signs and traffic light. Camera calibration process is necessary due to the fact that "Stop" sign's distance from the car needs to be calculated. Traffic lights are checked only if they signal red or green light. When speed limit sign is detected and cropped from a frame, this fraction of image is transferred to an OCR [6] (Optical Character Reading) module which is specialized to recognize digits only.

Lane detection is done by specifying ROI to road part only. After that, filtering by color is implemented, which finds white and yellow parts of the frame. In the next step picture is blurred and canny [7] edge detection process is performed. This feature assumes that camera is in the center of a car and predicts the angle needed to turn the steering wheel to keep the car in the current lane. After all detections and calculations, data is transferred to control node.

D. *Control node*

Control node is in charge of the whole system, by generating vehicle control signals and sending those inside different ROS topics. This unit exchanges information with image processing node and cruise control node. It collects the necessary data needed for vehicle control signals generation. Image processing node sends the information about detection of "Stop" sign with calculated distance, number read from speed limit sign and predicted angle of steering wheel turn to control unit. When information arrives, this part of the system is responsible for checking if distance to "Stop" sign is sufficient in order to stop the vehicle. If this is the case, node produces breaking signal.

When predicted angle is received, calculation of difference between current and predicted angle of steering wheel is performed. If this difference is smaller than predefined threshold, signal for steering wheel rotation is generated. This is done to prevent sudden rotations.

Also this node is receiving maximum allowed speed signal from image processing unit and driver desired speed from cruise control node. It combines those two signals and sets vehicle speed to maximum allowed if driver set speed is greater than limit. This can be overwritten by the driver if same, greater speed, is required twice. On top of all mentioned features, this part of the system has watchdog timer function as well, which is required to turn off autonomous driving system if something goes wrong with camera sensor or the image processing node.

E. *QT Application*

This part of the system simulates vehicle itself. It interacts with user and shows which control signals are generated and sent from control node. Starting complete system, entering wanted vehicle speed and monitoring of all control signals can be done through application. Application is able to show processed frame which is used for keep lane function. The screenshot of application behavior is presented in picture below.

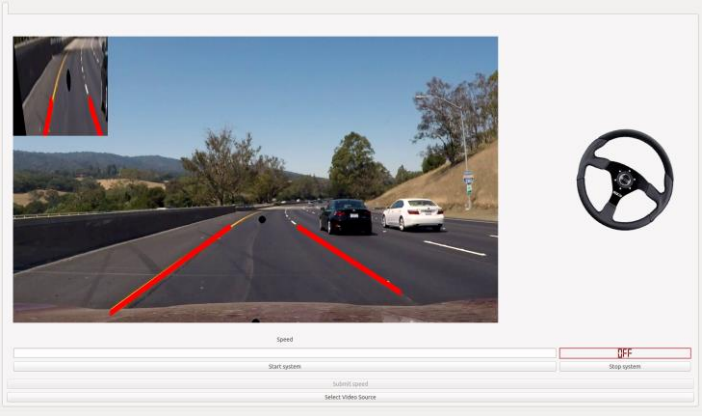

Fig. 4. Application screen shot with graphic user interface

F. *Watchdog node*

Watchdog is an electronic timer that is used to detect and recover devices from malfunctions. They are commonly used in embedded systems, such as this one. During normal operation of the system, watchdog timer is reset. In case that timer is not reset due to hardware fault or program error, this node's timer will elapse and generate timeout signal. When timeout signal is generated this node will try to recover the whole system to a working state if it is possible. Importance of this part of the system is high due to safety procedures in automotive industry.

G. *Cruise control node*

Modern cars cannot be imagined without cruise control function. This part of the system is in charge of collecting user defined speed. When user enters desired speed, this node collects this information and transfers it to control node, which will in return decide the actual driving speed. Also through this node, cruise control function of vehicle is being turned on or off, according to the driver's desires.

IV. RESULTS

Testing of system is done in multiple ways. Speed limit and "Stop" signs detection processes are tested automatically

using test scripts. System has its own log file system which is used to dump detected data inside. Script is run automatically when prerecorded video ends, to check if all detections are done correctly.

Keep lane function is tested visually by monitoring prerecorded camera video and calculated steering wheel angle. Unit and integration testing is done in this research too. It is done by using *google test* and *google mock* library. Mocking the objects is designed with use of DI (Dependency Injection) design pattern. In figure, below output of testing script used to test system is presented.

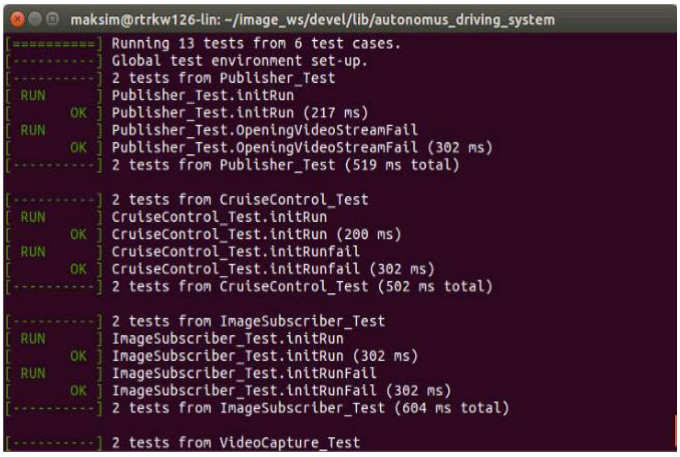

Fig. 5. Output of testing script used to check system functionality

Code coverage is measured using *gcov* [8] tool. In this work, due to very strict safety procedures which are very important in automotive industry, memory management is tested using *Valgrind* [9] tool. Static code analysis is performed due to high safety standards. Research done in this work is checked with MISRA 2004 guidelines using PC-lint [10] tool.

V. Conclusion

Contribution of this work is successful implementation of previously defined algorithms used in self driving cars. This research shows how combination of multiple independent building blocks are used to make a self driving system. Demonstration includes definition and development of algorithms for vehicle control using camera sensor. Algorithms shown in this investigation are:

- Keep lane function where software components are keeping a vehicle in current lane.
- Detection of "Stop" sign and its distance calculation due to stopping car in appropriate distance to this sign.
- Speed limit sign recognition and reading with intelligent vehicle speed control using neural networks.
- Traffic light detection with appropriate vehicle control according to traffic lights

The fact that this system uses only one camera sensor, proves that there are many possibilities for future improvements. More sensors can be added to the system, such as lidar and radar, then a fusion of sensors outputs could be made to get a better view of vehicle environment. By selection of ROS as the base platform of this work, program code is platform independent. Next step could be transferring the whole system to other platforms such as *AUTOSAR* framework.

Administration tool for multi-sensor imaging system

***Abstract*— Rapid development in imaging technologies as well as computer science bring both software and hardware improvements to systems used in military and surveillance fields, but there is a constant trade-off between adding new software features and lowering the system's security. Every new feature implemented in such system can potentially be a weak point for individuals with malicious intent. Particularly in multi-sensor imaging systems, initialization process of system itself is the weakest point, when no IP address is acquired, but system is powered on. Also, worth mentioning is the necessary use of static IP addresses, to avoid any DHCP Offer or other magic packets. However, there is a need for remote administration, especially since these types of systems are often found on distant locations. This paper presents a solution applied in such system and gives comments about which programming language should be used, recommended tools for enabling remote administration itself, as well as security shortcomings of such approach.**

***Index Terms* — System administration, multi-sensor imaging, Java, ONVIF protocol, remote system configuration.**

I. Introduction

Modern surveillance systems consist of multiple imaging sensors, cameras capable of different wavelength capturing, which work in tandem to provide best image available for further processing[1]. Picture acquired in this way is suitable for image algorithms, such as object tracking, motion detection, etc. Illustration of such system, and of the potential use-case scenario for service application presented in this paper is shown below (Fig. 1). Camera systems, based on Nvidia Jetson TX2 embedded computer board, communicate internally through a private local area network, with access to a wide area network ensured through a gateway. Operator's console on which the administration tool presented in this paper is running, is connected through Open Network Video Interface Forum - ONVIF protocol[2], which ensures encrypted data transfer as well as secure instruction set exchange.

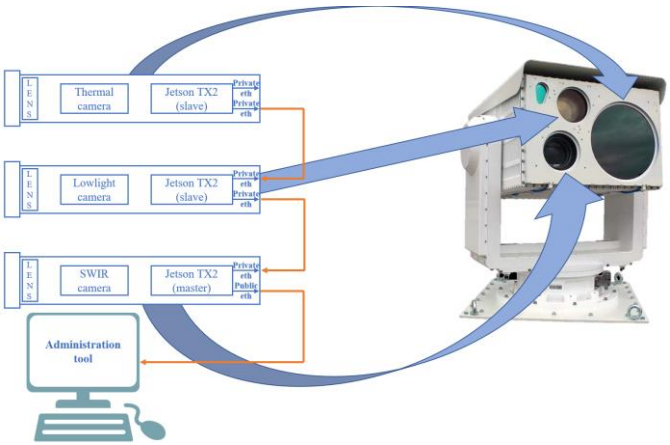

Fig. 1 Illustration of multi-sensor imaging system

With the swift development of both software and hardware, and quick adoption rate of new technologies which widen the abilities of traditional systems, there is an increasing demand for applications which serve to observe remote systems as well as log their activity. This phenomenon is especially pronounced in the security and military fields, where system failure can cause major problems. That is why it is important to have reliable software which can monitor system health, change basic parameters crucial for system functioning and observe any changes to the environment. This type of application faces a difficult trade-off between functionality and too much access to the system and its' resources. On one hand, the greater the number of tools available to user, the more possibilities there are for remote operation, which lessen the chances for obligatory site visits, but on the other hand, it leaves more room for potential harm-doing software and persons with malicious intent[3]. Having that in mind, it is important to define all needed options this type of application should have, and build it with only those operations available, which is why other existing solutions may not be acceptable.

Another thing worth considering is computer knowledge of applications' users, operating systems which will be used to run it and situations where it will be used. For example, it is not recommended to build an internet-dependant application when users have limited or no access to it.

One more thing to keep in mind is user's knowledge of English language, which is sometimes taken for granted, but it is not always the case that the user is fluid with all the technical terms and naming standards. Which is why intuitive software and placement of elements within the Graphical User Interface – GUI is very important[4]. Also, the language used in these types of applications should be as simple as possible, and use of whole sentences should be avoided in all cases except informational screens and logs.

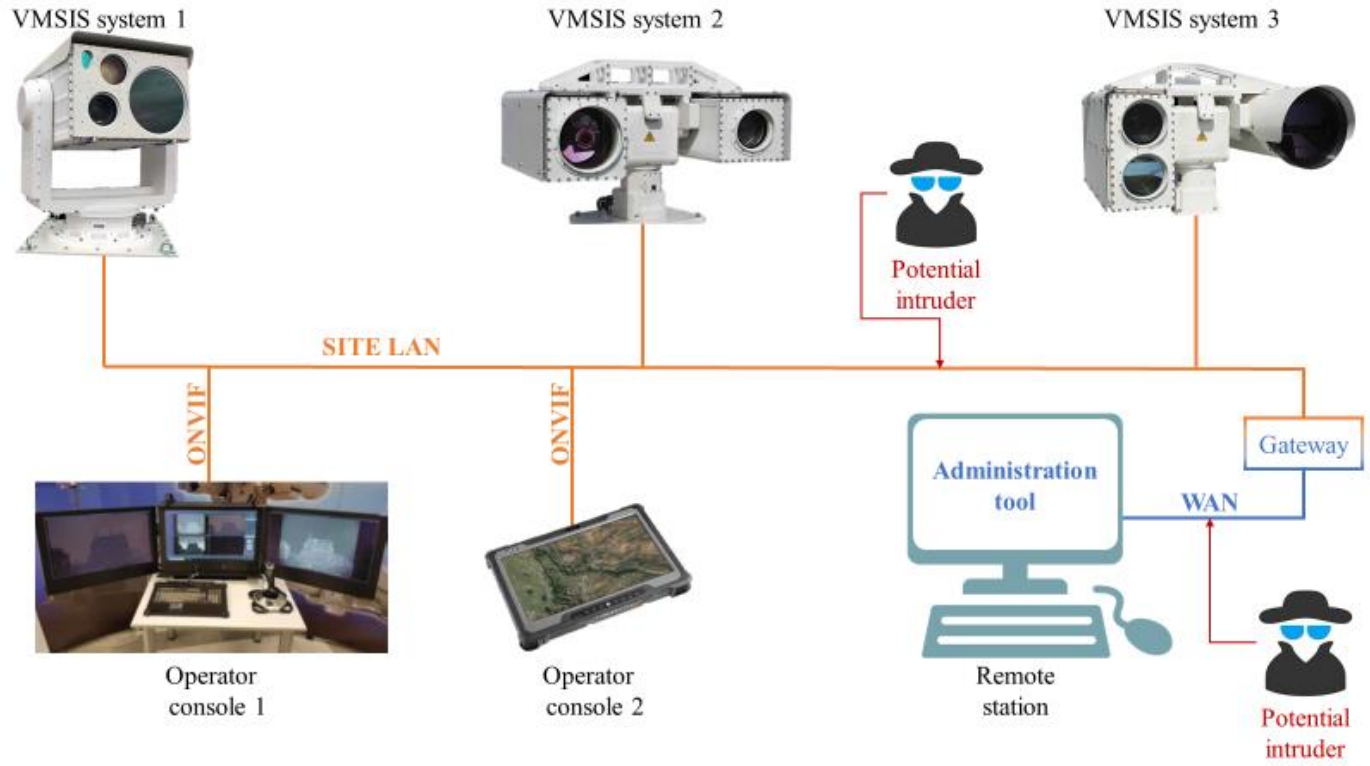

Fig. 2 Network structure on surveillance site

These types of systems are most vulnerable upon power on. At that point, if the system has no IP address assigned to it, potential intruder can manipulate it by giving the system an IP address of his choice, leaving it completely exposed. VMSIS is a server-type device with a static IP address and problems can arise when irregular address is used or assigned one is forgotten. Unlike SOHO networks, simple factory reset can't be used, because of system complexity. Once the power on sequence is finished, security measurements are passed on to the communication protocol of higher level, in this case ONVIF protocol. Network structure on surveillance site, with potential weak spots, is shown above (Fig. 2).

Advantages of this protocol compared to other ones, for example SNMP, is that it is built from ground-up with surveillance and video systems in mind. Since ONVIF is an open industry standard, its adoption rate is measured in hundreds of IP security manufacturers, leading to great interoperability among IP security devices. Also, having a universal protocol, which all manufacturers can use, benefits the developers as well, since software written for one compliant device will work on others without any alterations.

The paper is organized as follows. The Section II describes the methods used in order to achieve remote administration, as well as tools implemented in order to provide the features of administration tools described in this paper. In the Section III system components are discussed, and system prerequisites for running the administration tool presented in this paper are listed. The section IV shows field testing results of the administration tool presented in this paper. The Section V presents conclusions and future work in this research area.

II. System Description

Most multi-sensor camera systems consist of modules which communicate with each other privately, and have at least one public interface that is used for external communications and surveillance. That public interface is used for all purposes of service application presented in this paper. This particular service application is built in Java programming language, since there are end-users both on Windows as well as Linux operating systems[5], so compatibility with both platforms was a strong requirement. Also, Java offers visual elements which can be easily combined to form an intuitive User Interface – UI. Another positive of Java is its' ability to use remote resources and communicate seamlessly with devices which provide information for system functioning. For the most part, this application uses Java Secure Channel – Jsch[6], which is a pure Java implementation of SSH2 (Secure Shell 2)[7], to provide the needed tools to the end-user. This type of approach supports secure remote login, secure file transfer, secure TCP/IP as well as X11 forwarding. Also, there is support for key exchange like diffie-hellman-group-exchange-sha1, diffie-hellman-group-exchange-sha256, etc. Further, one of the features is connection through HTTP Proxy, as well as SOCKS5 proxy. This implementation gives the ability for port forwarding, stream forwarding and SSH File Transport Protocol, among other protocols. Everything mentioned allows the integration of all needed services which are essential to monitor these types of systems. Those include,

changing the network parameters of the remote host, such as device IP address, subnet mask, and default gateway, modifying both system and hardware time, downloading logs collected on the machine, both ones generated by operating system itself, syslogs, as well as those generated by proprietary applications which run on the system.

Another functionality implemented in the service application presented in this paper is remote host finder. This is especially important for systems designed to work only with static IP addresses, since some host may lose its' set IP address due to some system error, or even get a dynamically assigned IP address, by a DHCP server connected to the system, accidentally by an operator or on purpose by a potential intruder. So, it is very important to have a way to find IP address of the system which is to be configured or checked for errors. Since all operations on the remote host rely on knowing the host's IP address, host finder functionality is implemented in such a way that it finds and lists all the connected systems to the same network on which the operator's machine, running this service application, is connected.

For all purposes of finding the lost or forgotten IP address, as well as other IP manipulations, java.inet Java packet is used. It contains various tools for manipulation with Ethernet packets. One of those is a sub-packet called InetAddress, and it contains necessary classes and functions for checking if there is a valid route to the given host or not. To speed up the search for connected hosts, multi-threading is implemented, about which will be more discussion in the System Components section.

Use of ONVIF protocol enables the administration tool presented in this paper to communicate with the multi-sensor imaging system, without compromising the system's security.

III. System Components

A. Java Runtime environment

The basic component for running the service application on the host machine is a Java Runtime environment installed and set up. This environment is a free download, available on Java's owner website, Oracle. It is available for all popular systems, Microsoft's Windows, Apple's macOS, as well as most Linux distributions, such as Canonicle's Ubuntu, CentOS, Debian and others. Installation process is simplified and is a linear procedure, requiring minimal effort from the user, following only the steps listed by the installer. The multi-camera sensor system doesn't have to have Java Runtime installed, which is a plus, as there is no need to modify an already running system. That said, service application presented in this paper can operate with any other type of system, just some of the functionalities won't be available. For example, host finder will work in any given network and system configuration. Functionalities such as changing the target IP address, the system clock, log downloading as well as ping, are built in such a way, so they will retain their usability as long as the target is running a Linux-based operating system.

B. Secure log-in

Since this type of system and service application is intended to be used in surveillance and military systems, security is an important part of its' functionality. Therefore, before user can access any of the application's tools, secure login is required. Parameters of this login are changeable only before the first use of the application itself, leaving less room for any potential attacks and password cracking. Credentials for application are explicitly given to the user, and are not distributed.

After successful environment setup and application starting, user will be greeted with the log-in screen as shown below (Fig. 3).

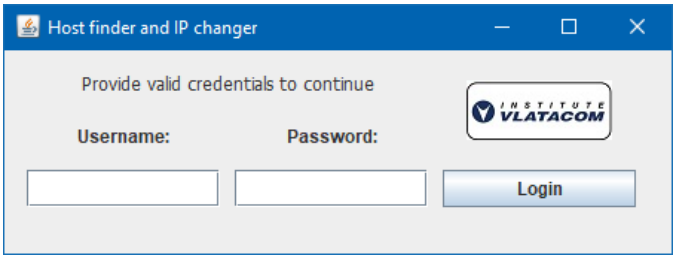

Fig. 3 Log-in screen

In case of valid credentials, user will be given access to the service application itself. On the other hand, if not, user will be informed about invalid combination of username and password, prompting for another try.

C. Service application main screen

Once the login is successful, user will be shown the main screen of the service application itself. It is worth mentioning that all functionalities provided by the service application are documented and described in detail in the manual which is supplied to the users alongside the service application. However, the form and presentation of the tools is composed in such a way that it tries to minimize the need for the manual.

Once opened, service application starts with the host finder tool on its' main screen. In the left part of the application, options for finding hosts are listed, while the right side is populated with some predefined, popular, subnets, as well as a button which leads to the part of the application that provides the user with options for changes on the system, but more on that later.

As shown below (Fig. 4), user has the ability to search only the predefined subnet, or just a given range of addresses, as well as conduct a full search of the whole network. In order to speed up this procedure, every query for an active host is started as a separate thread[8], up to a maximum of 65025 (255*255) threads. This is done to shorten the procedure, since every host has a time out of 200ms to respond, after which the request is discarded meaning that no host is connected on the given IP address. If a host replies in the meantime, it is registered as active and shown in the text area on the bottom of the service application.

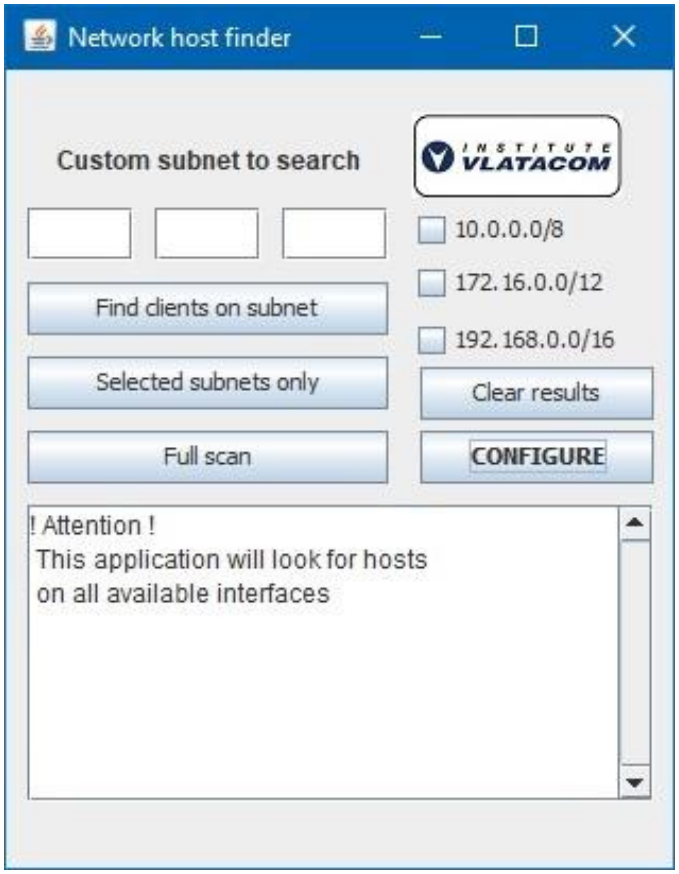

Fig. 4 Network host finder

Multi-threading may not be necessary when small networks are in use, but combination of using multiple threads, as well as setting the timeout limit to an empirically tested number, speeds up the procedure dramatically. The timeout itself can be set to a smaller or bigger number depending on what can be expected of the network and connected hosts.

The polling for active hosts is done by sending ICMP (ping) packets. While most tools rely on using ARP packets, solution presented in this paper doesn't implement that method, as some network firewalls may interpret sending that many ARP packets from one host machine as an attempt to destabilize the network, or as a flooding attack, and disconnect the host. On the other hand, ICMP packets are small, predefined, and are allowed in almost all networks, which makes them ideal for this purpose. Upon reply from the host connected to the network, its' IP address will be shown in the main window of the application. Order of IP addresses will be such that it matches the order of received replies, meaning that the hosts with smaller latency through the network will be on the top, and more distant ones, with bigger propagation latency, near the bottom.

D. Remote system connection

Once operator has the IP address of the system which needs to be configured, connection to that system has to be established in order to proceed to the device administration. Connection to the system is done through the connection panel, which is shown below (Fig. 5).

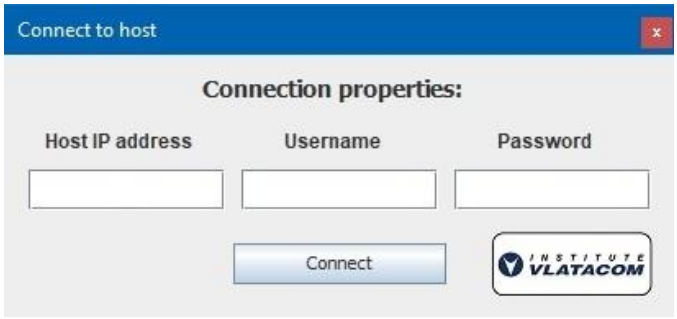

Fig. 5 Connection panel

System parameters used to connect to the device are the same as the operator would use to connect using a standard SSH connection[9], or in other words, IP address of the system which is to be administrated, username of an account on the machine, as well as password for that account.

E. Device administration

Upon successful connection to the system, device administration panel will open. This part of the application contains main tools for changing the system parameters as well as checking the system's health. It is not recommended to leave system parameters susceptible to change all the time the system is powered on, so a security feature is implemented which disables the ability to change the IP address as well as other network parameters after 5 minutes upon powering on. However, there is a way for this to be overridden, by using the button in the top left corner, which allows the user to change all system parameters, but only after providing a predefined administrator password. By doing so, one more security measurement is added through adding another step of authentication. The image below (Fig. 6) shows the state of the service application once the system has been powered on for more than 5 minutes and administration privileges are not granted.

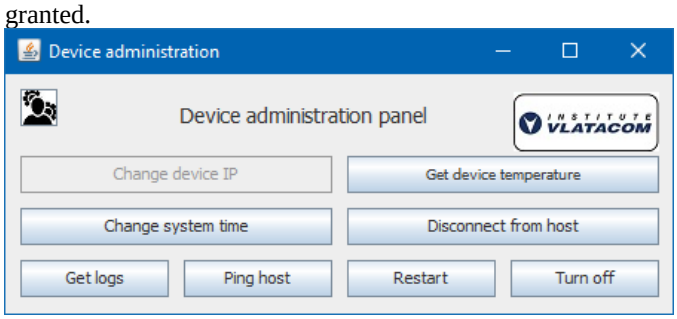

Fig. 6 Device administration panel

As already mentioned, button Change device IP will allow the user to make needed network adjustments, such as changing the IP address of the machine, setting the new gateway address, as well as changing the subnet. After successful parameters change, user will be disconnected, so the new parameters can be set on the remote host.

Another feature enabled by service application presented in this paper is the ability to change system software and hardware time. Before changing, the user will be informed about current time. The mentioned feature, along with its' GUI element is shown below (Fig. 7).

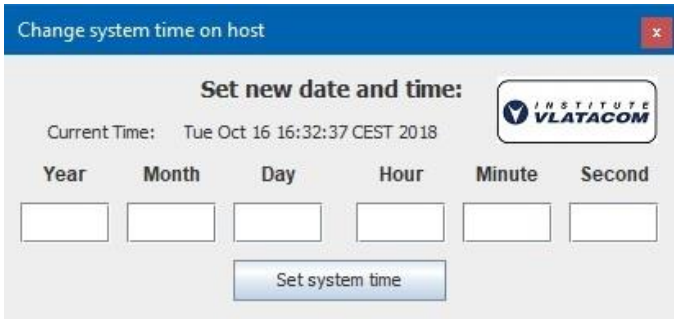

Fig. 7 System time modification panel

For any system intended to be operative for longer periods of time, it is essential to keep log of its' activity, which can be extremely helpful to diagnose a cause of an eventual system failure, or even if everything is running correctly, observe the system state. With logging implemented, tool for downloading those logs from the remote host is found in the lower left corner of the administration panel and once used, the user will be presented with a progress bar of the downloads. Among the Ubuntu's syslog files, log files generated by a proprietary logging tool are also downloaded.

Checking the connection between the host running the service application and the remote host can be done by pinging the remote host using the implemented tool. This feature presents the user with latency present in the network, as well as time needed for the remote host to be reached.

System health can be checked in various ways, depending on the implementation of the system, there are various parameters which can best represent its' state. In this implementation, system temperature is of special interest, that is why, solution presented in this paper has the ability to display to the user, temperature measured by the system.

Among other features, the operator has the ability to remotely reset the system, or power it off. It can be useful in some conditions where system isn't working properly to have a way to restart it remotely, without having to go on site.

F. Additional improvements

Adding the ability of downloading the recordings captured by the multi-sensor imaging system would be the next logical step in improving the administration tool. Also, addition of an informational file which would contain detailed information about the system, and the ability to download it remotely would see benefits in diagnostic speed, as the operator could easily identify components and prepare for needed repairs without having to go on site and look for what parts are installed.

IV. FIELD TESTING

Administration tool presented in this paper has already been field tested in the capital city of United Arab Emirates, Abu Dhabi. Fig. 8 shows the naval surveillance site in the bottom left corner of the figure, network connection used, operator console room with administration tool running on operator machine, on the bottom right in the image, and an image from the multi-sensor imaging system, VMSIS, in the upper portion of the picture. Note that even in the simplified setup, device is 10m above ground and factory reset button isn't accessible.

Fig. 8 Administration tool on surveillance site field testing

V. CONCLUSION

Modern surveillance systems are improving by day, and those improvements bring lots of additional features, but increase the system's overall complexity. One of those improvements comes from the ability to have multiple cameras, or multi-sensor camera system which can extrapolate signals captured by all of the cameras and then combine them to create a picture of higher quality. Image generated in that way can be better used for further processing, whether it be to detect an object in the image, track an object, or something entirely different. But all those improvements come at a cost of increasing system intricacy, since every imaging channel requires a subsystem which has a built-in processor, and an image processing hardware. All of those components have a chance of failing, that is why the need for administration tools is increasing.

One solution of DTV simulator for PC platform

Đorđe Glišić, Aleksandar Šuka, Aleksandar Plahćinski, Miodrag Đukić

***Abstract* — User requirements of digital TV receivers grows increasingly, so does the complexity of embedded development process. Current STB devices range from cheap low memory device to multi-core device with performance comparable to PC or mobile phones. Low cost devices present a specific challenge in development, as the stability and performance is more in focus than on high performance devices. Limitations in the development of software for digital television showed the need for the development of tools for analysis and testing. This paper presents one solution to overcome limitations of target platform. DTV software stack is taken and adjusted to be used on PC to get sophisticated development tools accessible.**

***Index terms* — simulator; digital TV receiver; software in digital television; Middleware; Middleware Testing Environment; hardware abstraction layer; Inter-process communication; SDL library; ffmpeg library; wxWidgets library.**

I. Introduction

Embedded devices in recent years show sudden increase in terms of performance, so *DTV* receivers no longer serve only for reproduction of television signals, yet they come with a set of additional functionalities, the implementation of which in time becomes more and more complex. Usually the development of software for embedded devices is slower than the PC platform. The main challenges are the lack of tools to detect programming errors, general tools for software development, as well as lack of hardware resources. Idea was to develop tool that could give us ability to use debugging tools at runtime, code coverage analysis and to automate testing of DTV stack as black box and in development.

Similar work was done in commercial DTV software, were aim was mostly toward supporting development of application part, but not around simulating whole DTV stack. One example of that is Observatory [1], that supports minimal functionality of DTV and focuses around UI development. Second more close solution working only on Linux platform is DVBCore [2], it supports DVB-T, DVB-C, DVB-S, and it has similar requirements for building on Linux. It uses older versions of underlaying libaries, limiting capabilities in UI presentation and reproduction, and does not provide version for Windows operating system.

The second chapter gives a general structure of software for *DTV* receiver, the aim is to create a sense of layering and modularity, which facilitates the implementation of the simulator.

The third chapter describes modules that had to be implemented on DTV stack in hardware abstraction layer for target platform. For simulation of hardware devices like tuner, demultiplexer, decoder we used libraries from open source community. For decoding and demultiplexing of content from transport stream we used *ffmpeg* library[3]. For audio and video reproduction, graphical presentation, as well as to send and receive user-generated events with keyboard we used *Simple DirectMedia Layer – SDL* library [4].

Chapter four describes second part of this solution, graphical environment that is used to control simulator from outside and to generate commands and receive simulator states. Environment is possible to send a number of test commands, to trigger a series of user and system activities. Communication between PC simulator and test environment is done using TCP/IP protocol.

II. Software for DTV receiver

Architecture of DTV software can be divided into: operating system layer and DTV drivers layer, hardware abstraction layer (*HAL*), *Middleware*, *Middleware* abstraction layer API *(MAL API)* and DTV application. Applications can be different from application running using build-in UI engines to external clients like Web browser or application written in Java (in case of Android OS) as depicted in Fig. 1.

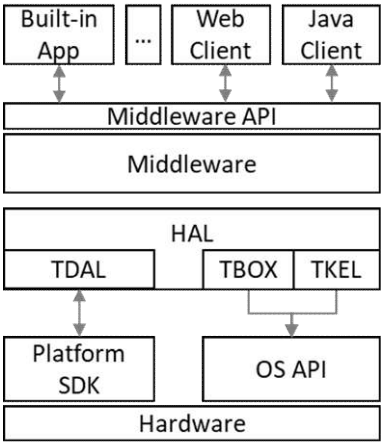

Fig. 1 DTV application architectural overview

A. Middleware

The *Middleware* layer is central part of the DTV stack, it is responsible for parsing DVB information, service management, access control, support for personal video recording (PVR), electronic programming guide (EPG), control reminders, controlling descrambling and decoding of

Aleksandar Šuka – RT-RK Institute for Computer Based Systems, Novi Sad, Srbija, (e-mail: Aleksandar.Suka@rt-tk.com)
Đorđe Glišić – RT-RK Institute for Computer Based Systems, Novi Sad, Srbija, (e-mail: Djordje.Glisic@rt-tk.com)
Aleksandar Plahćanski – RT-RK Institute for Computer Based Systems, Novi Sad, Srbija, (e-mail: Aleksandar.Plahcanski@rt-tk.com)
Miodrag Đukić – RT-RK Institute for Computer Based Systems, Novi Sad, Srbija, (e-mail: Miodrag.Djukic@rt-tk.com)

multimedia content and so on. Middleware controls data flow for multimedia content, from one or more modules in HAL layer. Middleware has defined API as seen in Pic. 1, that is used by user application or other clients, depending on the actual architecture and platform. The role of the user application layer is to control the display of graphic elements, and to define the behavior of the application that interact with the user. Key point for reusability of the middleware is that its code is platform independent, in a sense that it does not assume particular architecture or uses any platform specific features. All system or driver dependencies are encapsulated through HAL layer.

B. Hardware abstraction layer

Hardware Abstraction Layer (HAL), is layer on which *Middleware* relies. This layer has strict predefined API serves to hides physical architecture of the *DTV* receiver, and needs to be implemented for every new targeted platform.

HAL consists of three independent units: *Thin Kernel Encapsulation Layer (TKEL)*, a layer for functional abstraction of real time operating system, *Tool Box (TBOX)* module provides I/O capability over serial connection (UART, TCP/IP etc.), and *Thin Driver Adaptation Layer (TDAL)* that serves as an abstraction layer for drivers which consists of many modules, each block of physical architecture of the *DTV* receiver has corresponding *TDAL* controller.

III. Adjustment of DTV Software to Targeted PC Platform

As part of the *DTV* receiver software adjustment to target platform it was necessary to implement hardware abstraction layer. This chapter describes the details of implementation used to port DTV stack to the *Windows* and *Linux* platform. It was selected to use built-in application as DTV application with stack as in Fig. 2.

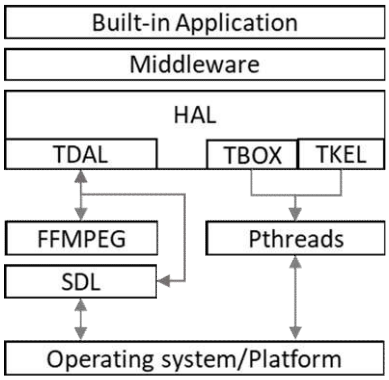

Fig. 2 Architectural overview of PC simulator for DTV

A. Adjustment of TKEL module for targeted platform

TKEL module implements functions that are specific to the used operating system, provides *API* for: semaphores, critical sections, creation of software threads, communication between program threads, memory allocation and deallocation, timers.

In this paper we used programing interface from *Pthreads* library to implement *TKEL* module parts related to the creation, synchronization and communication between threads - tasks. *Pthreads* is *POSIX* standard directly supported on *Linux* platforms, unlike the *Windows* operating system, which in this case it was necessary to include *Minimalist GNU for Windows* (*MinGW*) solution. As a result, we got code which does not depend directly on the programming interface provided by the operating system, and accordingly it is not necessary to maintain separate *Windows* and *Linux* version as shown in Fig. 2.

Exchange of data between tasks in the operating system adaptation module is provided by using message queues. As queues are simple structures, there is no difference between this implementation and the implementation of the DTV receiver. Attention is paid only to synchronization, depending on the system calls typical for the targeted platform, for which was used the same module as described in the section for synchronization between tasks.

On DTV receiver timing is achieved using special thread that is blocked, and signaling to that thread takes place every hardware cycle and every cycle of that thread is one unit of time. On the targeted platform, the part of hardware that performs signaling is switched by system signaling.

B. Adjustment of TBOX module for targeted platform

The main role of *TBOX* is to enable communication of the *Middleware* with the system environment for the purpose of performing debugging output via the serial interface. *TBOX* allows multi-level printing, such as: critical prints, warning, monitoring hierarchy calls, general printouts.

Adjusting *TBOX* module comes down to the implementation of *TBOX* as a tool to print to standard output or to output for errors.

C. Adjustment of TDAL module for targeted platform

TDAL is driver abstraction layer, which allows the use of physical architecture of *DTV* receiver by the *Middleware*, without needing to know the details of the implementation of that architecture. *TDAL API* is the most comprehensive *API* and most complex for porting to targeted platform. *TDAL* is modularly organized, and so that in most cases one *TDAL* module corresponds to one block of the physical architecture, one module can be viewed as the driver handler from the point of *Middleware*.

In the following section are given solutions of how some of the modules from *TDAL* are implemented.

1) Adjusting the block that controls demodulator

Block that controls demodulator and set the reception at a specific frequency *TDAL_DMD* [8] is responsible for managing the physical network module. Some of the roles are: setting up reception at a certain frequency, performs search on a given frequency band, notifies other modules of the important events related to the reception, provides access and control parameters of signal quality.

Within the simulator input data are represented as a transport stream in a digital format. The process of signal demodulation has been done already in the process of recording a transport stream. Complete transport stream that would be obtained as an output from the demodulator is in the file. In addition to the file that contains *MPEG-TS* data, there is a configuration file that contains all the information necessary to describe the signals that are obtained by the process of demodulation. *MPEG-TS* data that are transmitted at different frequencies are stored in separate files, when adding a new *MPEG-TS* file it is necessary to modify the configuration file. Each line in the configuration file specifies *MPEG-TS* in the following format: the frequency at which *MPEG-TS* is being broadcasted

expressed in Hz, path to *MPEG-TS* file, signal quality which is set in the range of 0 to 100, the signal strength, which is applied in the range from 0 to 100, speed at which data is transferred expressed in number of bits per second, comments in the configuration file begin with * and they do not interpret.

During initialization of the block that controls demodulator, the configuration file is being parsed. Parsed information are stored in the structure and later used to set the reception at a specific frequency – *tuning*. Setting the reception at a specific frequency for us means positioning to the next *MPEG-TS* file. Signals the library *ffmpeg* which first deinitializes old contexts for formatted input and output, and then initialize the new contexts. After the opening of the new context library closes previous, and then opens new file. When opening the file, functions to read the file and positioning within the file are provided. It is also necessary that the local structures for the management of the demodulator is filled with information from the current *MPEG-TS* file, after which the system is ready to fetch new data.

2) Adjusting the block that controls demultiplexer

The role of the *TDAL_DMX* [7] module is to manage the demultiplexer to separate the audio/video components, *Packet Elementary Stream (PES)* packages and filters *Service Information (SI)* sections [5].

TDAL_DMX module allows the creation and deletion of channels, which are used for the delivery of data by type of channel. The channels may be of different types: video stream, audio stream, PCR stream, teletext stream, stream for subtitle, stream for sections etc. Each channel is dependent on the correct one *packet identifier – PID*. Within the channel, *TDAL_DMX* allows usage of filters that additionally filters data from transport stream. Two modes of filtration are supported: positive filter (client requires filtering according to certain criteria, *TableId*, *ExtensionId*, *VersionNumber*) and negative filter (client requires fetching sections that do not contain specific criteria).

How hardware support for demultiplexing on *PC* platform does not exist, we have implemented demultiplexer in the TDAL_DMX module. Functions, for reading and positioning within *MPEG-TS* file that we registered to *ffmpeg* library, shall be fetching data. The data in this case are the packets. Special demultiplexing thread is reading data and applies filtering, first on the basis of *PID* value, and then on the basis of defined filter, if one exists. Given that *ffmpeg*, itself, may differ audio and video packets from other *PSI* packets, we used that ability so in demultiplexer thread goes only data related to *PSI* packets. *PSI* packets are after filtering grouped into sections, that are by *callback* function passed to the *Middleware*.

3) Adjusting the block that decodes audio and video packets from elementary stream

The role of the *TDAL_AV* [11] module is to fully control the process of decoding video and audio *PES* packets. Within *DTV* receiver the physical audio and video decoders are controlled directly. On PC platform decoding function performs library *ffmpeg*, to display content we used *SDL* library. Below it will be explained how the audio and video decoding process is implemented, forming video frames and displaying of synchronized audio and video content.

Block that reads *MPEG-TS* file is implemented using *ffmpeg* library. As we stated in part for demultiplexing, library can distinguish audio and video packets, so depending on the type of packet, package is sent to the block for video processing or into the block for audio processing.

Block for video processing takes sent video package, decodes it, forms a frame and synchronizes its display. Then *SDL* library is informed to allocate space for a picture and based on frame creates video texture for displaying. Showing is realized by the timer that signals *callback* function, that joins part with graphic and part with video texture and refreshes the display.

In the audio processing block is defined callback function, in which are audio packets collected, decoded and synchronized. This function is passed to library *SDL* when audio and video content are being played.

4) Adjusting the block that controls graphical rendering

TDAL_GFX [9] serves as a loop which is used by the application to display a graphical user interface. Some functionalities of module for graphical rendering are: graphical regions management, color palettes management, transparency level management, bitmaps manipulation and drawing, filling a rectangular region with color, blit command to combine multiple bitmap and multiple regions into a single final image.

The graphics module used in the simulator relies on library SDL. The library provides the concept of texture and the concept of region, as the *Middleware* expects graphic layer and windows within the graphic layer, we used texture as a graphic layer, and regions represent windows within a layer. Rendering graphics comes down to going through all regions and bliting with texture.

Initialization of graphic layer boils down to creation of graphic texture and initialization of ten free regions. When the *Middleware* is prompted to create a new region, *TDAL_GFX* finds the next available region, creates texture for a specific region and returns to *Middleware* handler for specific region. All drawings are related to a texture region. Using *SDL* library primitives can be rendered, for complex images are first created bitmaps, which are then glued to the texture Blit function we implemented so that, in addition to the gluing bitmap on the texture of region, it can perform sticking color to bitmap, as well as some memory content on bitmap.

The content of the graphic texture is copied to the display, together with the content of video texture described in the section referring to the video decoding. Refresh the display gets the final image.

5) Adjusting the permanent memory management block

TDAL_FLA [12] module is responsible for providing access to *flash* permanent memory. *Flash* memory is divided into blocks, predefined size.

In the simulator the file is opened during the initialization of the permanent memory management block. File is mapped with buffer, and further manipulation with permanent memory comes down to operations with buffer.

6) Adjusting the block for receiving user events

In the case of *DTV* receiver for receiving and processing user events is responsible *TDAL_KDB* [10] module. For each user action on the remote control, *TDAL_KDB* module generates an event that can be received and processed in order to carry out certain actions. *TDAL_KDB* module supports the following events on the keys of the remote control: key is pressed, key released and key is hold. Physical codes are translated into *Middleware* codes using configuration files.

Instead of an infrared remote control as an input device to generate a user event parameters are utilized with the keyboard. To receive events generated by the keyboard we used structure and program interface offered by *SDL* library. For event handling *SDL* library offers a collection of events. For the purpose of the simulator we used fields that relates to keyboard events. The structure for the events from the keyboard has a field type, which can have values pressed or released which allows us to distinguish events key is pressed or released key. Key identifier is read from the field symbol keys which are then mapped to the corresponding code that is sent to the *Middleware*.

The mechanisms for receiving user control event distinguish between two threads. The first thread receives user events over the functions of *SDL* library and sends it to another thread over a common buffer, while another thread processes event and calls the appropriate *callback* registered by the *Middleware*. Running PC simulator is depicted in Fig. 3.

Fig. 3 PC simulator at execution time (Windows version)

7) Adjusting the block for playing multimedia content

The main job of the *TDAL_MP* [13] is to control audio/video playback of multimedia content from local hard disk, extern flash memory or extern hard disk connected via USB plug. Module allows to play, pause, stop, rewind or fast forward reproduction.

Within *DTV* receiver, drivers capable of decoding specific multimedia coding are already present on board. In case of PC simulator, we used feature of *ffmpeg* which distinct audio and video packets, provides access to a single package, the fields and content, as well as content decoding. It has support for a large number of audio and video codecs, as well as container formats. In simulator extern storage memory is simulated with directory on PC platform local hard disk.

After opening multimedia file, there are three threads that control: reading data, decoding of audio and video packets and performing their reproduction. Functions for file reading and positioning within the file are provided to *ffmpeg,* after that using those functions *ffmpeg* reads packets from elementary stream and decodes them. For displaying video content and playing audio content, is again used *SDL* library.

It was necessary to implement function used to manipulate playing of content. Rewind was enable by function which changes position in file. Fast forward function skips parts of file periodically so that frames are displayed with longer time intervals in between, different sets of arguments for speed increase or decrease distance between presented chunks.

8) Adjusting the block for conditional access

Conditional Access System (CAS) is a mechanism by which television services can be accessed if the relevant provisions of the term of use defined by the digital television provider are met. The need for a conditional system occurs whenever the commercial content is transmitted over to the user by unsafe networks and is used to protect the content of television services transported by satellite, cable or terrestrial systems for the transport of digital content.

Within the elementary stream each packet has a header, that contains information relevant to the transport protocol itself and a segment containing useful data, for example, audio and video. Scrambling takes place at the packet level and only segment containing useful information is encrypted, header remains the same. Main task of *CAS* is to process *Entitlement Control Messages – ECM* and *Entitlement Management Messages – EMM*, descramble encrypted packets using *Control Words – CW* located inside *ECM* and responds to messages to request transported over *EMM*.

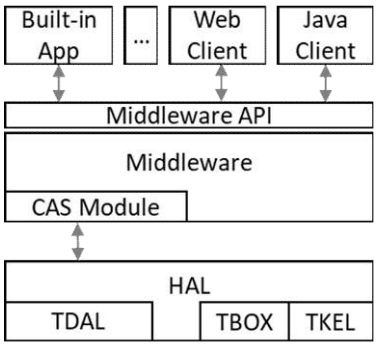

Fig. 4 Conditional access system module

Since library for descrambling is kept in privacy by *Conditional Access Provider*, when adjusting *CAS* to PC platform we had to bypass all the details concerning scrambling and descrambling of content obtained through the transport stream. Existence of descrambling block is abstracted so testing is possible only on streams that are not scrambled. Module is part of middleware Fig. 4, and is only module modified that is not part of HAL. Testing of *CAS* and its importance will be explained in following chapter.

IV. Middleware Testing Environment

In order to assure satisfying test results it is necessary to have a number of test procedures established at various levels. Testing is which, in addition to the software itself, checks all accompanying components and features. Testing is a process that involves a large number of activities and is closely related to software development itself. Bearing in mind that the errors are relatively frequent, it is necessary to introduce a quality control system that will serve for early detection of errors and their removal.

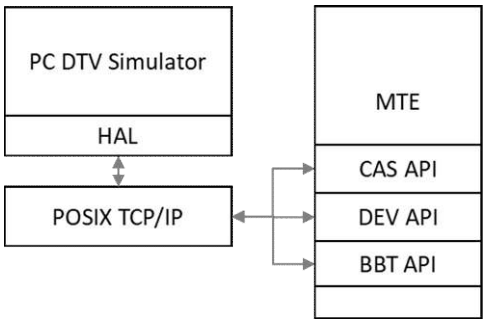

Fig. 5 Communication between PC simulator and MTE

The idea is to develop special modules with a graphical environment that would facilitate work. Their existence in the long run saves a lot of time that would otherwise be spent on writing tests, which ultimately promotes the development of the product itself. Also, in some situations, when several different parties work on development of different modules of the same product, their testing may require the cooperation of several parties. In this case, having a tool that would be standardized during testing can further promote the development itself.

Environment used for the purpose of testing middleware is the *Middleware Testing Environment – MTE* as given in Fig. 5. Graphical environment is developed in Python using wxWidget library, and consists of window that mimics *Remote Controller* and *CAS Middleware Testing Environment – CAS MTE* window.

From user point of view, using keyboard is not practical. Purpose of *Remote Controller* in *MTE* is to enable interaction between user and PC simulator. Beside obvious functionality which is sending events to *TDAL_KBD* module, *Remote Controller* supports *Logging* mechanism as well as environment for automatic testing. It allows to search and filter output from PC simulator using *Logging* mechanism. It is also possible to make automated tests in the form of a series of commands that are generated individually in the *MTE Environment*, send it all together via generated communication stream and execute sequentially on the simulator. Control over digital content is also possible from MTE, PC simulator and MTE can communicate sources as tuple (file name, frequency, signal quality, and bit rate) as seen in Fig. 6.

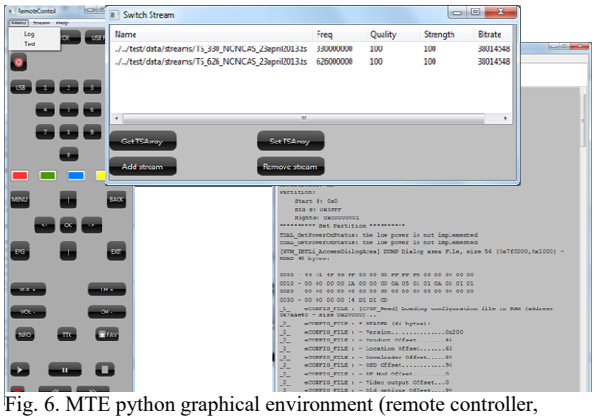

Fig. 6. MTE python graphical environment (remote controller, logger, stream picker)

Part of MTE is dedicated to CAS simulation. It is implemented to send commands that will simulate actual CAS system. On PC simulator side there was need to implement CAS module that would receive commands and process them. It was not possible to use any proprietary CAS libraries as they are not available for PC. Data exchanged simulates use cases for real data that would come through stream in *STB* environment from proprietary CAS. Some of use cases are: access permissions to certain services, fingerprint security, popups, smart card states, email messages.

Simulator for DTV and MTE are two different applications which are also written in two different languages C and Python. Reason behind splitting this was to minimize performance and memory impact on DTV software in execution and to move all the user interaction away from simulator. Communication was realized through TCP/IP protocol using sockets. In simulator HAL layer, which is used to work with sockets, is using *Winsock* library in case of *Windows OS* and *Berkeley sockets* library in case of *Linux OS* [14].

With given MTE environment following features have been tested and checked for functionality flaws:

Table I
Group of tests that were executed using MTE

Test group	Result
Switching services	*PASS*
Electronic programming guide	*PASS*
Personal video recording	*PASS*
User settings	*PASS*

Automated testing reduces amount of time developer has to do manual testing, and removes possibility of missing test cases. Currently test cases prepared for this work take about 10 minutes to execute, where developer will take more than half hour. On the other hand, with implantation of CAS module it is possible to test scenarios that would otherwise require additional resources.

V. Conclusion

With this work we have shown that it can make a fully functional environment for the development of digital TV applications supported by *Windows* and *Linux* platforms. This would mean that all the solutions in the *Middleware*, which does not depend on the hardware performances, can be developed on PC platform, which exceeds the unavailability of hardware and software complexity in the process of software development for embedded systems. Also, *MTE Environment* is designed so that it can easily be adapted for different projects and leaves a lot of space for its further development.

From perspective of development, all possible IDE's that have analytic capabilities like Eclipse, NetBeans, Visual Studio and many others can be attached to PC simulator for debugging. On MTE side, it is also possible to attach IDEs for debugging python execution. It has been tested for both PC simulator and MTE to be run in debugging mode simultaneously.

From perspective of quality assurance, automatic testing black box testing [15] was implemented to help validate changes done in development. Aim of the paper was to expose work that had to be done to create working DTV simulator, and not so much about testing, so it was not given in detail.

Further directions of development PC simulator can go toward adding support for descrambling of protected digital content, adding support for IPTV, adding support for multiple outputs (SD and HD) and supporting for web clients. On MTE side, development should focus toward

improving automated testing, DTV content generation and run-time modification that would allow testing all possible scenarios. This gives the possibility of simulating the operation of the entire television network.

ACKNOWLEDGEMENT

This work was partially funded by the Ministry of Science and Technology of the Republic of Serbia, the number of technological development project: III_044009_2.

Reproduction of high quality object-based audio content using GStreamer multimedia framework

Srđan Šuvakov, Jelena Kovačević, *Member, IEEE*, Dejan Bokan and Andrej Popović

***Abstract* — The new generation of audio technology introduces a significant increase in audio processing demands from playback devices. The implementation of such technologies for embedded devices represents a challenging task. By using an already existing multimedia framework, we can speed up the development process, but most of the state of the art multimedia frameworks do not support new types of audio stream formats such as object based audio. This paper describes the process of extending the GStreamer multimedia framework with support for object-based audio stream playback. A new GStreamer plugin for rendering audio objects, has been created. The plugin receives and prepares the object-based input stream, invokes the rendering function and after the rendering is finished, the plugin sends the rendered data to the next element in the GStreamer pipeline. This paper also presents a method for audio objects and metadata transfer between GStreamer. The plugin is evaluated on an ARM based SoC device running Linux OS.**

***Index Terms*— Object based audio coding, Audio object rendering, GStreamer, Embedded, Audio systems**

I. Introduction

Over the past few years, we have witnessed a significant progress in developing new technologies for audio content processing, distribution and delivery. Most of these advancements are aimed towards enabling lifelike, scalable and interactive audio experiences to consumers across a wide range of devices and applications. Some of the key properties of modern audio content is spatial realism and immersion. Immersive audio content provides an accurate representation of the spatial attributes of an audio program while providing user experiences that engage our sensory system in a more natural way – allowing sensory systems to process information in a way comparable to how listeners experience the natural world by providing more realistic and natural auditory cues to the listener. [1]. Modern audio technologies allow extending existing mix practices, sound mixers can use music, effects and dialogue in new ways. This allows content creators with the ability to deliver significantly improved, personalized and immersive experience to consumers as shown in [2].

In order to achieve the immersive experience, modern audio technologies usually combine several elements for producing an audio scene, such as: object based audio representation, enhanced height surround sound, and advanced virtualization algorithms. Introducing these new technologies significantly increased the complexity of the tasks performed by audio playback devices. Additionally, these new technologies are being introduced not only as part of high end audio devices, but also in different home audio systems, in-vehicle infotainment systems, mobile devices etc. Thus real time implementation of these technologies has become an important and ongoing topic.

Modern multimedia and infotainment systems are commonly based on System on Chip (SoC) platforms [3]. The audio DSP cores found in most SoCs lack the processing power required to execute new generation complex audio processing technologies on their own. There are two effective solutions to this problem. One is simply increasing the number of audio DSP cores in the SoC or adding additional Audio DSP chips to the device. This solution does not resolve the problem of adding support for modern audio technologies within the existing audio device designs. The other solution to enable support for complex audio processing technologies is to use the application processor for audio processing. This would enable new audio technologies to be implemented within already existing hardware.

In most SoC based multimedia systems application cores are used to execute operating system and user interface tasks. Providing support for multimedia tasks within the OS is usually performed using a multimedia framework. One of the commonly used frameworks is GStreamer [4]. GStreamer is an often used framework when it comes to developing real time media processing and playback solutions for SoCs. GStreamer is an open source project developed by the GNU community. It is written in programming language C, and it supports multiple OS (Windows, Linux, Android, iOS, Mac OS X). Examples of GStreamer being used for playback, recording and streaming in different multimedia systems can be seen in [5], [6] and [7]. GStreamer framework is designed to make it easy to write applications that handle audio or video or both. The pipeline design is made to have little overhead above what the applied processing modules induce. This makes GStreamer a good framework for designing even high-end audio applications which put high demands on latency. GStreamer framework enables easier porting of existing solutions to other SoCs that support the GStreamer framework. Although GStreamer contains support for an extensive set of plugins and tools for streaming, decoding, formatting and processing traditional channel-based audio content, there is currently no support for any form of object based audio representation.

In this paper, GStreamer's functionality is extended with support for object based audio stream playback. An existing

audio object rendering module is used to create a new GStremaer plugin. Additionaly, support for a new type of stream and metadata handling is added to GStreamer framework.

The object based audio renderer was built as a static library. To run the object based audio renderer within GStreamer a new plugin was created. This plugin would serve as an interface between GStreamer and the object based audio renderer, the plugin receives and prepares the input stream, and after the rendering is done the plugin sends the rendered data to the next element in the GStreamer pipeline. The plugin was implemented on *Raspberry pi 2 model b* as it includes an ARM based chip, which are very prevalent in multimedia SoCs.

II. Object Audio Coding

There are two approaches to 3d audio scene reproduction, channel based and object based [8]. With channel based audio the number and position of the speaker setup must be predefined. This means that any audio content has to be mastered for any speaker setup on which we want to reproduce it on, trying to play audio content mastered for one speaker setup on a different one may result in loss of audio content. Object audio coding has no such issue [9]. Every object in object based audio coding contains audio content for reproduction and its proprietary metadata. This metadata contains additional information that is used to accurately reproduce the audio scene, such as the position of the audio content, its gain as well as its trajectory, if its position changes over time. Thanks to metadata, object based audio systems offer more flexibility when it comes to speaker setups. This also means that the complexity of audio reproduction devices increases, as it's now up to the end device to not only decode, but accurately render the audio scene as well. The added complexity also makes it more difficult to implement object based technologies in existing hardware.

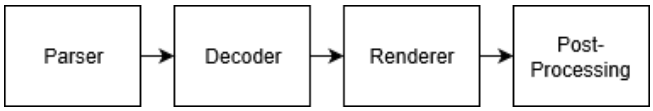

Figure 1 Data processing order within object audio processing systems

There are many different approaches to object audio content distribution and reproduction (such as MPEG-H[10], Dolby Atmos[11] etc.). While different in many ways, the basic principles are similar. Each approach needs to simultaneously unpack objects and metadata, ensure their synchronization and rendering. Accurate rendering requires a pre prepared model of the reproduction room. The creation and presentation of that model is not covered in this paper as that process differs greatly for each object based audio technology. The post-processing of object based audio does not differentiate much from post-processing within channel based audio technologies. Modules dedicated to rendering object audio content receive audio objects that contain raw audio content along with its proprietary metadata from the input stream. The module then renders the audio content from the audio objects according to metadata. Depending on the object audio technology, and its use case, the rendered audio content is then either sent to a post-processing module or towards an audio output, such as speakers. The object rendering module in most object audio technologies is situated between the decoding module and the post-processing module, as is shown on figure 1.

III. GStreamer Framework

The GStreamer framework provides a pipeline mechanism that allows a complex audio system to be divided into several major functionalities and be developed independently of one another. A *bin* in GStreamer is container for a collection of elements. As bins are GStreamer elements themselves, they can be controller as elements, thereby abstracting a lot of complexity of the developed application. For example, you can change the state of all of the elements within one bin by changing the state of the bin. A *pipeline* is a top-level bin. It provides a data buss and manages data flow and synchronization between its elements. Once started, pipelines run in a separate thread until stopped. GStreamer also allows for a pipeline to be split into multiple threads, for example when both video and audio needs to be decoded simultaneously. An example of one pipeline instance can be seen in figure 2.

Plugins are a core building block for the GStreamer framework. Each plugin has one specific function, such as decoding, reading data from a file, outputting to a file or sound card etc. By linking plugins together a pipeline that can do a specific task is created, for example a pipeline for media playback. Each plugin has input and output ports called "Pads". These pads are used to negotiate links and data flow between plugins in GStreamer. Each pad has specific data handling capabilities, or *caps* for short, and will only allow data flow between plugins with compatible pads. In addition to providing a pipeline mechanism, GStreamer also provides an extensive set of tool that cover media type handling, synchronization between pipeline elements and a vast library of existing plugins that provide multimedia processing functionalities. These functionalities include a collection of parsing, decoding and post processing algorithms implementations for both video and audio content. Additionally, there are plugins for handling input and output transport streams, which allow receiving multimedia content from different sources (file, disc, network stream, etc.) and directing audio to a specified output. [4]

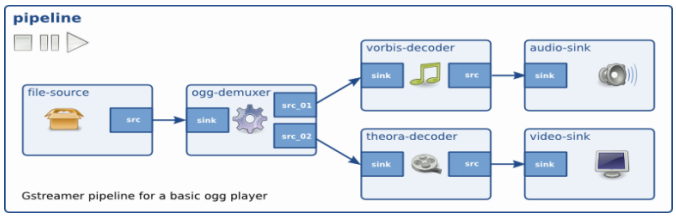

Figure 2 Gstreamer pipeline example

GStreamer offers base classes that provide base functionality for some types of plugins. These classes provide everything required for a plugin to function within the GStreamer framework, meaning that they only need to be expanded with the functionalities that the plugin itself is designed to perform.

IV. Plugin Implementation

As it was stated in the introduction, an object rendering module from an already existing object based audio solution was used

as the base for the created object rendering plugin (ORP) in GStreamer. The rendering module is given in form of a prebuilt C library. The ORP plugin serves as an interface between GStreamer and the rendering module itself, it receives and prepares all the necessary data for the rendering module, invokes the rendering function and afterward it sends the rendered data forward along the pipeline. *BaseTransform* was used as the base class for the ORP. *BaseTransform* is commonly used as a base class for plugins that have raw audio content on both input and output pads. Plugins which extend the *BaseTransform* usually modify only audio content, preserving the format, but it also contains a capability to change audio format (number of channels, sample format, sample rate etc.). This makes is a suitable base class for a module that would transform input objects into a channel based stream that could be reproduced on a variety of speaker configurations. In order to create ORP, *BaseTransform* class is extended and the following functionalities were implemented:

- Caps negotiation and transformation
- Bitmask formation
- Metadata handling
- Rendering

A. *Caps negotiation and transformation*

Caps negotiation is a process between two connecting GStreamer elements in which the output capabilities of the output pad of one element is compared to the input pad of the other to determine if they are compatible with one another. In most GStreamer elements the output caps are inherited from its input caps. The ORP expects audio objects with metadata on the input and sends raw channel audio containing rendered audio scenes to its output. The output caps of ORP are set based on audio scene model which is loaded during module initialization. Output caps of ORP are not negotiable, which means that input pad of successor plugin must match them. These caps are always in form of raw audio content with the possible format parameters:

- Number of channels: 1 to 23
- Sample rate: 1 to 96000
- Audio format: S32LE - 24 bits in 32 bits, unsigned, little endian
- Channel layout: interleaved, non-interleaved

The input caps of ORP are set based on output caps of previous plugin in the pipeline. GStreamer currently does not have ability for identifying object based audio stream. A new identifier for this type of stream is introduced, and named: "Audio/object-audio", the possible audio parameters for object audio content are the same as with raw audio content, with the exception that the number of channels now represents the number of objects being transmitted. Each decoder which has the ability to decode object based audio needs to be modified to support this caps identifier, and to emit the extracted metadata with the audio content.

B. *Bitmask formation*

Since the audio channel bitmask of the object rendering module that was used in the ORP differs from GStreamer's bitmask, the two needed to be aligned. The object rendering module requires the used channels mask to be in the form of a string. For example for a stereo stream that uses the left and right speaker, the string that is sent to the ORP is "LR". The string is then parsed and list of GstAudioChannelPositions is filled. The list of audio channel positions is then turned into a mask by calling the gst_audio_channel_positions_to_mask() function. Alongside the GstAudioChannelPositions list, the function also requires the number of channels. The bitmask created in such a manner is then set as the output channel bitmask by calling the gst_value_set_bitmask().

C. *Metadata handling*

Object audio relies on metadata to provide information needed for accurate reproduction of the audio scene. GStreamer framework contains a mechanism to transfer some additional information about the stream which is referred to as "metadata". But in GStreamer terms, metadata can contain only a small number predefined fields with the information on the properties of the stream (such as its format, type etc.) and as such cannot be used to transfer the metadata needed for object audio rendering. This problem was solved by creating an additional buffer for object audio metadata which is sent alongside the audio content. Specifically, a new buffer is created that encompasses all the metadata required for one frame to be rendered. That buffer is then bound to the main buffer containing audio data that needs to be rendered, and that is achieved using the using GStreamer's ability bind the life expectancy of one buffer to another. This binding is performed using *gst_buffer_add_parent_buffer_meta()* mechanism, which adds a reference to the metadata buffer, as shown in figure 3, and prevents the parent buffer to be returned to the buffer pool while the child buffer is still in use. Additionally a class containing the new metadata structure as well as its functions needed to be made. The functions contained in this class provide functionalities such as initialization, filling and registering the metadata structure with its implementation name. Registering a metadata structure is required so that it can retrieved from the metadata buffer later by using its implementation name.

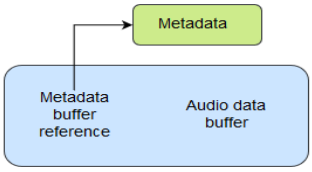

Figure 3 Binding the metadata buffer to the audio data buffer

D. *Rendering*

While the rendering itself is done within the rendering module, as the interface between GStreamer and the module, the task of the ORP is to handle the data prior to, and after the rendering is done. When a new input buffer is received on the ORP input pad, a function called gst_renderer_transform() would be called. The gst_renderer_transform() contains all the rendering functionality such as buffering, rendering and preparing the output stream. After a buffer is received from the input stream, its metadata buffer is extracted using the gst_buffer_get_parent_buffer_meta() function. It is possible that one audio data frame contains more than one metadata frame. After the metadata is extracted, the metadata frames are counted. The entire content of audio data is placed in the input FIFO structure. For each metadata frame, the rendering function is invoked with the FIFO structure as audio input. The rendering module renders audio samples covered by one

metadata frame and increases the FIFO pointer. After rendering all the samples covered by one metadata frame, the rendered audio is placed into the output buffer. This process is repeated while there are still unprocessed metadata frames and enough audio data in the FIFO buffer for the rendering of current metadata frame. After all metadata frames are processed, the output buffer is resized to fit the number of samples rendered, and sent towards the next element within the pipeline for further processing. In case there are samples left in the FIFO buffer after all the metadata frames were rendered, this data is preserved for the next rendering cycle. As GStreamer has the ability to change the size of the buffer transferred between elements of its pipeline, in case that the amount of samples that were rendered is less than the set size of the output buffer the object renderer plugin will resize the buffer to fit the actual size required to transmit all the rendered samples. One example of dataflow in ORP is shown on the figure 4.

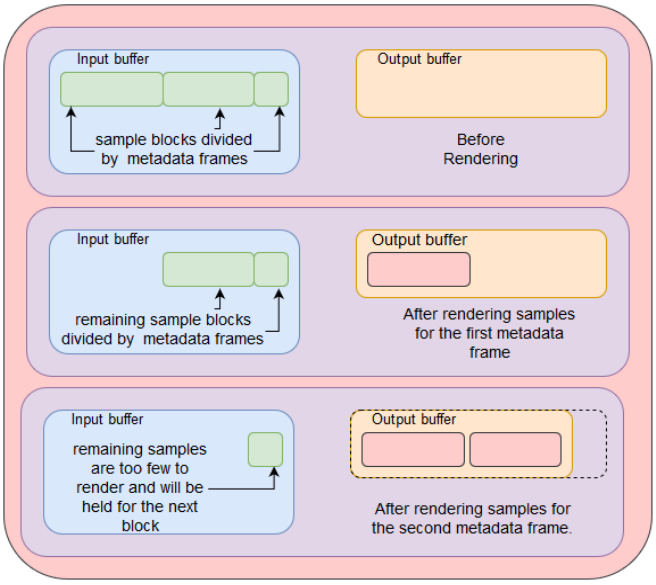

Figure 4 Visual representation of the rendering process for one block of samples

V. TESTING AND RESULTS

The end goal for the ORP was running it in embedded devices. For this purpose the testing was done on Raspberry Pi 2, as it is a good example of a Linux embedded device with GStreamer support. The full test environment is given in table 1.

As previously stated, the rendering module expects objects and their metadata as its input stream. This would normally be done within the decoding or parsing modules, or even the combination of the two. As neither of the two have a GStreamer implementation that supports object audio processing, for the purpose of testing the rendering module, a separate module was created that will load pre prepared objects with their metadata, pack them into a buffer and send them to the rendering module. The module was named "Loadfile" and uses basesrc class template. As its input, this module expects an XML file. This XML file contains the location and names of all the object files and their metadata on disk. The audio object were pre prepared and each object was stored as a separate uncompressed WAV file. Metadata files for all objects were stored in a single file.

Table 1 Test environment

Platform	Raspberry Pi 2 model B
SOC	Broadcom BCM2836
Instruction set	ARMv7-A (32-bit)
CPU	4× Cortex-A7 900 MHz
OS	Raspbian stretch 1.4.6
GStreamer version	Gstreamer1.0
Audio output:	Analog out, HDMI

A. *File I/O test*

The ORP was tested using a pipeline created using GStreamer's gst-launch-1.0 tool, which builds and runs GStreamer pipelines from elements passed as its arguments. The pipeline created by gst-launch-1.0 can be seen in figure 5. The resulting file would then be compared with the output file of the reference object rendering module. This output file was created by running the reference module binary, built for the raspberry pi.

Figure 5 ORP file I/O test pipeline

B. *Real-time test*

The gst-launch-1.0 also enabled the pipeline to be executed in real time. This is done by setting the last element of the pipeline to alsasink. The Alsasnik plugin uses system audio output, such as analog output or HDMI output. The HDMI output was recorded using RT-AG[12]. RT-AG is a digital audio grabber and player with support for both analog and digital audio playback and recording. RT-AG supports recording of up to fourteen channels, and recording up to eight channels at frequencies of up to 192kHz and a depth of 32 bits per sample. The test setup is shown in figure 7. The RT-AG connects to the PC using the Ethernet port to ensure a lossless transmission of high quality audio content. Real time test were executed using a script from the pc. The script would copy test stream files to the Raspberry Pi and run the pipeline shown in figure 6 using gst-launch-1.0. The stream would then be sent through the HDMI to RT-AG . RT-AG would record the stream and send it to the pc through the Ethernet port. The stream would then be saved on the PC as WAV file. This file can then be compared to the output file of the reference module generated on the PC.

Figure 6 ORP real-time test pipeline

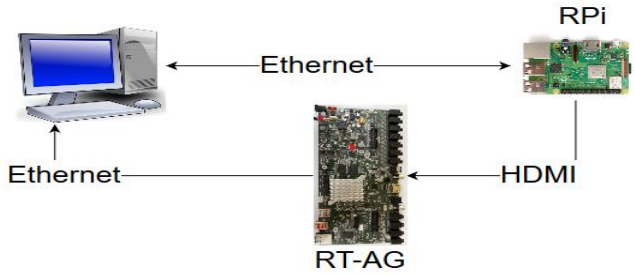

Figure 7 Raspberry Pi 2 connected to RT-AG

C. System resource utilization

After it was determined that the outputs of the reference module and the implemented module were bit exact, the CPU usage of the module was calculated. This was done with the help of the Linux *Perf* tool [13]. Perf tool was used to get performance information of the module such as the total amount of cycles that the implementation used and the running time of the implementation. Perf was also used to calculate how much of CPU time was used for the rendering module itself, as Perf was counting this information for the whole audio chain, including the Loadfile, converter and sink. The final calculation was expressed in MIPS (Millions of instructions per second) and was done by using the following formula:

$$MIPS = \frac{nr\_cycles * \frac{R}{100}}{1000000 * total\_time}$$

Where "R" is the percentage of CPU utilization of the rendering module itself, divided by 100 to normalize it. Table 2 contains the MIPS calculations using the test from the certification package of the object based technology used as the base for the GStreamer plugin. The results from Table 2 show that the rendering time, as well as the processor usage represented in MIPS, doesn't linearly scale up with the amount of objects nor the stream duration. As the object count increased the amount of time it took the module to render an audio scene did increase, while the amount of MIPS the module required didn't change. For example we see that the tests three through five have the lowest amount of MIPS required, even though they are the longest streams with the largest object count. That is due to the stream only having general speech in it that would sound off on which audio channel, and by proxy speaker, it should be positioned. In contrast, the shortest stream from test eight with a relatively low amount of objects has the highest MIPS count. That test used a complex stream that contains a full audio scene that consisted out of ambient sounds as well as foreground noise, fully utilizing the rendering capabilities of the rendering module. On the other hand the rendering time for tests three through five, all of which contain 11 object, compared to their duration was around 80% of the stream duration, while the rendering time of test eight, which contains 3 objects, was 61%. But, these test have shown that, even in the worst case scenario that happened in test eight, that required 383.986 MIPS to run, or 42.66% of a single CPU core, the Raspberry Pi 2 is able to run it on a single core with no issues.

VI. Conclusion

This paper aimed to present GStreamer as a viable option when it comes to the development of new generation audio technology solutions for the embedded devices. The CPU usage alongside the real time tests confirm that GStreamer is able to render objects in real time. With further testing that includes implementing the complete audio reproduction chain within GStreamer as well as utilizing GStreamer's ability to split the pipeline into multiple threads to run the decoder and renderer simultaneously, GStreamer could become a very viable option for embedded media streaming devices that would eliminate the need to add additional dedicated DSP cores. This would also have the added benefit of using GStreamer is lowering the development time for new technologies as GStreamer can reuse the reference code, only requiring an interface to be able to execute it. Most DSP based solutions on the other hand require the whole reference code to be ported and adapted to fit their architecture.

Table 2 MIPS calculation results

Test	Object count	Output channels	Stream duration [s]	Render time [s]	CPU usage [mips]
test_1	1	8	2	1,071	344,640
test_2	1	8	2	1,03	331,969
test_3	11	2	30	23,141	176,272
test_4	11	8	30	23,921	172,595
test_5	11	8	30	23,479	178,689
test_6	5	6	2	1,24	312,563
test_7	5	6	2	1,23	281,501
test_8	3	8	1	0,61	383,986
test_9	1	8	2	1,009	284,937

Spectral Analysis of Male and Female Speech Signals

Omar Zelmati, Boban Bondžulić, Milenko Andrić, Dimitrije Bujaković

***Abstract*—In this paper a spectral analysis is applied on a male and female speech audio database. The effect of unsounded audio signal parts on the spectrum rate is studied and it is shown that silent parts disturb strongly the spectral analysis and these parts should be deleted. A comparison between different spectra is made based on correlation. For the case of the spectrums that origins from the same speaker, it is shown that these spectrums are strongly correlated, while a significant correlation between spectrums of the same speaker's gender is highlighted. Finally, the effect of audio signal duration on the spectrums correlation is discussed. The obtained results are very promising and can be used in several fields of speech signal analysis such as speaker recognition and speaker gender identification.**

***Index Terms*— Spectral analysis, Speech signal, Correlation.**

I. Introduction

ANALYSIS of speech signal has various applications such as speaker identification, automatic speech recognition, speaker gender recognition, speech enhancement, etc. In recent years, many researches have been carried out in order to take some advantages of the spectral analysis benefits over the speech time analysis.

As it is stated in [1], spectral analysis (known also "Fourier representation") is often used to highlight certain properties of the speech signal that may be hidden or less obvious if the signal is represented in time domain. These properties are extracted from a spectrum using different techniques and, furthermore, they can be exploited in various methods according to the application and the purpose of the research. Various approaches and implementations in order to extract features of spectrum have been studied in literature [2], such as Discrete Fourier Transform (DFT), and its fast implementations: Fast Fourier Transform (FFT) and Short-Time Fourier Transform (STFT).

Regardless to the signal type, Fourier representation aims to decompose it into its frequency components [3]. For the special case of speaker recognition, numerous signal decomposition techniques based on DFT are proposed. Moreover, some alternatives such as non-harmonic bases, aperiodic functions and data-driven bases derived from independent component analysis have been discussed, and their effectiveness has been placed in evidence [4-6]. However, because of its simplicity and efficiency, DFT is used in practice and usually only the magnitude spectrum is considered, based on the belief that phase has little perceptual importance [7]. The overall shape of the DFT magnitude spectrum, called spectral envelope contains information on the resonance properties of the vocal tract and has been found to be the most informative part of the spectrum for purpose of speaker recognition [1].

Dynamic spectral features (spectral transition) as well as instantaneous spectral features play an important role in human speech perception [8] and many researches on feature extraction for isolated word recognition have investing the effectiveness of using spectral features. In [9] it is shown that Mel Frequency Cepstral Coefficients (MFCCs) are the robust features for isolated word recognition. In this research these coefficients are calculated in six steps: pre-emphasis, applying Hamming windowing, frame blocking, FFT, Log Mel spectrum calculation and applying Discrete Cosine Transform. Furthermore, MFCCs and other measures like pitch, log energy and mel-band energy, have been fixed as based features for emotion recognition using speech signal in [10].

Linear Prediction Coding (LPC) method is applied for speaker gender recognition in [11]. LPC method is such a filter applied on the FFT in order to spectrally flatten the input signal. Beyond its use in gender recognition, this method has been used in speech enhancement and particularly for noise reduction [12].

In this research the spectral analysis of recently formed database of audio signals is performed. Spectral analyses are done regard to the speaker gender (male or female) and as the measure of spectral properties of different speakers the correlation between spectrums of the recorded audio signals is used. These correlations are analyzed for different speakers and for different texts. Beside this, the effects of the audio signals duration are also analyzed through the correlation between male and female speakers.

The rest of paper is organized as follow: in the Section II the used audio signals database is described; in Section III it is applied spectral analysis based on FFT for audio recordings of used database through three analyses: speaker-based correlation, text-based correlation and analysis of the duration of speech signals on the correlation between various speakers.

In the last part of this paper, results are discussed and some conclusions are highlighted with some direction of further research.

II. Description of Speech Signals Database

For the purposes of the male and female speech signal analysis, an audio recordings database is created with the recording of five already prepared texts in the Serbian language read by five male and five female speakers. As each speaker read five texts, the complete database consists of 50 audio records. The duration of each record is about 30 seconds.

All speakers are aged between 20 and 25 years (students of the Military Academy in Belgrade). In order to guarantee the same environmental conditions of recording, the recording is done in the same place, in a sound-isolated room. All voice recordings were recorded using the SpectraLAB software package on a DELL laptop, with sampling rate f_s = 8 kHz and 16-bit resolution. As input, the microphone of the headphones for the VoIP communication Genius HS04S is used. The sensitivity of used microphone is –60 dB, while its frequency response is within 50 Hz and 20000 Hz.

Audio recordings contain words used in military terminology (gun, pistol, airplane, attack, defense, etc.), so it represents a good basis that in further research they can be used for isolated word recognition or for speaker identification.

III. Speech Signals Spectral Analysis

In this research the FFT of the recorded audio set is applied in order to calculate the correlation between the different obtained spectrums. Although the recording is done in special conditions, the segmentation step is necessary in order to eliminate the effect of the background noise in the spectrum form. All analyzed speech signals are preprocessed due to elimination of the audio signal silent parts. The algorithm for silence removal is proposed in [13] and in this part of the paper is briefly described. The method of silence removal is based on two audio features, the signal energy and the spectral centroid. The applied algorithm consists of four stages:

1) Extraction of the signal energy and spectral centroid from the already decomposed sequences of audio signal;

2) Thresholds estimation for each sequence, where two thresholds are calculated on the base of the extracted features;

3) Application of thresholds criterion on the audio signals sequences, and

4) Speech segments detection based on the threshold criterion and post-processing.

Firstly, the audio signal is divided into non-overlapping frames of the same duration (in this research the frame duration is 50 ms), where $s_i(n)$, n = 0,…, N-1 are the audio samples of the i-th frame of length N. The energy of one frame of audio signal can be calculated using:

$$E_i = \frac{1}{N}\sum_{n=0}^{N-1}\left|s_i(n)\right|^2. \quad (1)$$

This energy is used to detect the silent frames presented in the audio signal, based on the assumption that, if the level of background noise is not very high, the energy of the voice segments is significantly greater than the energy of the silent segments [13]. Silent segments may contain environmental sounds, and for that reason, the measurement of the spectral centroid is performed. The spectral centroid of low energy segments is much smaller, as these noisy sounds tend to have lower frequencies and, as a result, spectral centroid values are lower [13]. If the $X_i(k)$, k = 0,…, N-1 are the DFT coefficients of the i-th frame of length N, the spectral centroid is calculated as:

$$C_i = \frac{\sum_{k=0}^{N-1}(k+1)\left|X_i(k)\right|}{\sum_{k=0}^{N-1}\left|X_i(k)\right|}. \quad (2)$$

After determining all voiced segments of the audio signal, the new-voiced signal is created using concatenation of all voiced segments of the original audio signal. Furthermore, the FFT is applied on each modified signal. Magnitudes of the FFT of an audio signal from created database before and after silence removal are shown in Fig. 1.

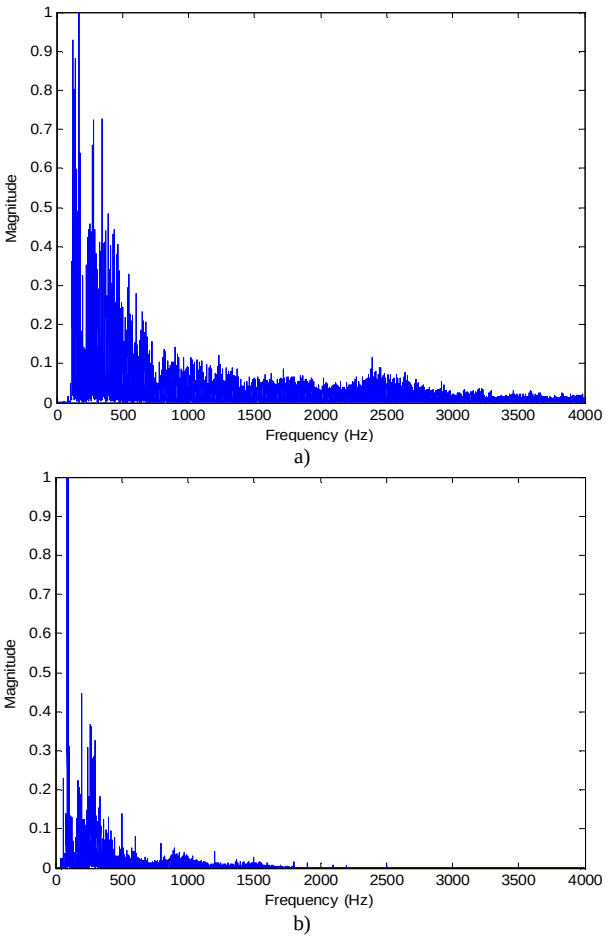

Fig. 1. Normalized spectrum of the audio signal: a) before silence removal, b) after silence removal.

Comparing spectrums before silence removal (Fig. 1.a) and after silence removal (Fig. 1.b), it can be noticed that silent parts strongly affect the spectrum shape. After silence removal, the magnitudes of frequencies above 1800 Hz are suppressed. The correlation between the spectrums of audio signal before and after silence removal is about 20%.

A. Speaker-based Correlation

In the first analysis, the spectrums of audio signals after silence removal of one speaker that speak different texts are compared. The normalized spectrums of audio signals from a one male (speaker 3) and one female (speaker 7) extracted from used database are shown in Fig. 2.

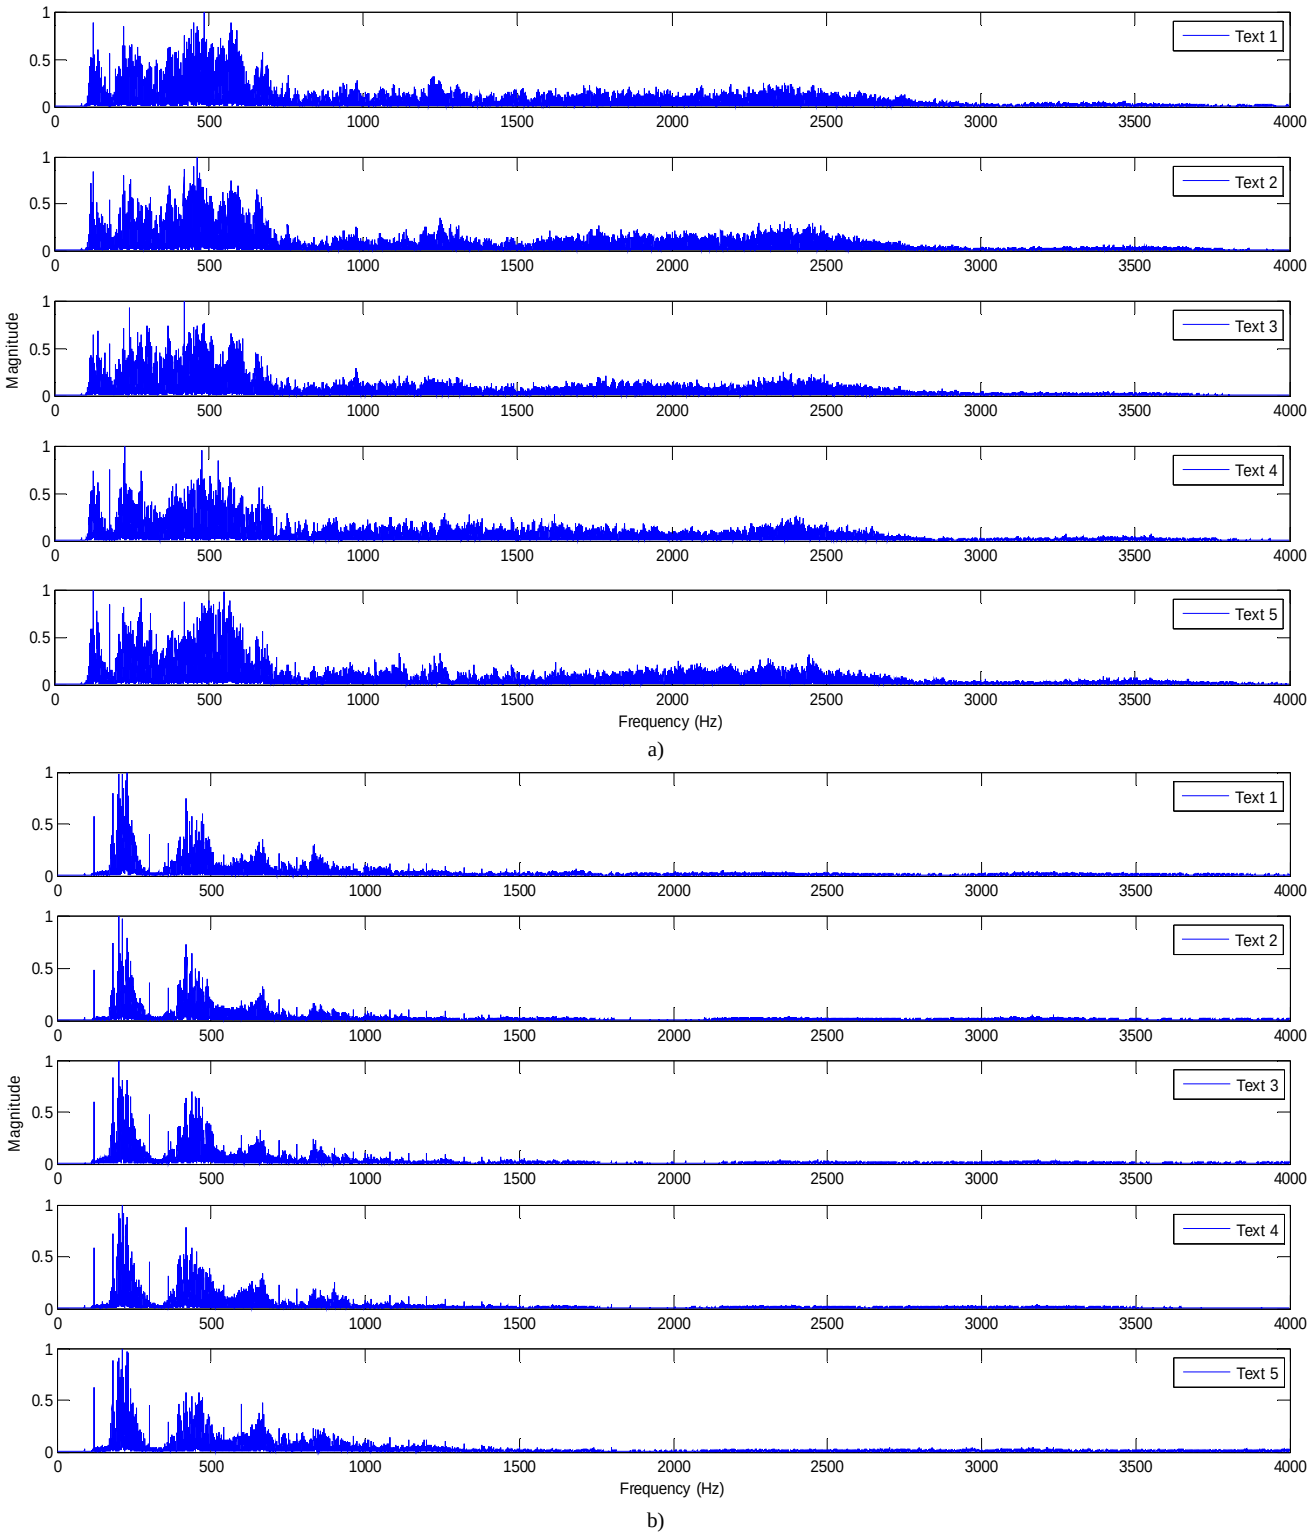

Fig. 2. Spectrums of the different audio speech signals for the same: a) male speaker (speaker 3) and b) female speaker (speaker 7).

From the Fig. 2, it can be noticed that signals origin from the same speaker and different read texts, have the similar spectral shape. Analyzing the spectral properties of male speaker (Fig. 2.a), it can be noticed that spectral components are wider, while for female speaker (Fig. 2.b), spectral components are concentrated around 200 Hz and 400 Hz. In order to quantify spectral similarity, the correlation of spectrum of audio signals produced by male and female speaker is calculated with regard to the spoken texts with and without silence removal. Results of this analysis are shown in Table I (male speaker) and Table II (female speaker).

TABLE I
SPECTRUM BASED CORRELATION FOR THE MALE SPEAKER

	Text 1	**Text 2**	**Text 3**	**Text 4**	**Text 5**
	Without silence removal				
Text 1	1	0.48	0.46	0.41	0.45
Text 2	0.48	1	0.47	0.40	0.43
Text 3	0.46	0.47	1	0.39	0.43
Text 4	0.41	0.40	0.39	1	0.40
Text 5	0.45	0.43	0.43	0.40	1
	With silence removal				
Text 1	1	0.69	0.68	0.66	0.64
Text 2	0.69	1	0.71	0.68	0.67
Text 3	0.68	0.71	1	0.70	0.68
Text 4	0.66	0.68	0.70	1	0.70
Text 5	0.64	0.67	0.68	0.70	1

TABLE II
SPECTRUM BASED CORRELATION FOR THE FEMALE SPEAKER

	Text 1	**Text 2**	**Text 3**	**Text 4**	**Text 5**
	Without silence removal				
Text 1	1	0.37	0.36	0.36	0.32
Text 2	0.37	1	0.37	0.38	0.32
Text 3	0.36	0.37	1	0.37	0.31
Text 4	0.36	0.38	0.37	1	0.32
Text 5	0.32	0.32	0.31	0.32	1
	With silence removal				
Text 1	1	0.70	0.68	0.68	0.65
Text 2	0.70	1	0.70	0.69	0.70
Text 3	0.68	0.70	1	0.71	0.71
Text 4	0.68	0.69	0.71	1	0.72
Text 5	0.65	0.70	0.71	0.72	1

Comparing results of spectral correlation presented in Table I and II, a high correlation can be noticed between the spectrums of the same speaker for different texts read either for male or for female in the case after silence removal while it is much lower for the case without silence removal. The highest correlation value is obtained for the female speaker (72%), while the lowest correlation is obtained for the male speaker (64%). However, the average spectral correlation for the male and for the female speaker is nearly the same: 68% for the male and 69% for the female speaker. From this, it can be concluded that spectral shape after silence removal may be used for feature extraction in order to perform speaker recognition.

B. Text-based Correlation

In order to determine the correlation between the spectrums of the same text uttered by different speakers, the correlation between the spectrums of different speakers is calculated on the text 1 with and without silence removal. The results of spectral correlations are shown in Table III. The part of this table colored in blue represents the correlation between spectrums of five male speakers for the read text, while the part colored in orange represents the correlation between spectrums of all the five female speakers for the same text. The yellow part of Table III is the spectral correlation between males and female speakers.

TABLE III
SPECTRAL CORRELATION OF TEXT 1

		Male speakers					**Female speakers**				
		1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**
		Without silence removal									
Male speakers	**1**	1	0.21	0.36	0.33	0.37	0.23	0.22	0.17	0.21	0.10
	2	0.21	1	0.25	0.23	0.24	0.14	0.10	0.14	0.16	0.08
	3	0.36	0.25	1	0.38	0.33	0.28	0.24	0.29	0.33	0.14
	4	0.33	0.23	0.38	1	0.35	0.22	0.20	0.24	0.26	0.15
	5	0.37	0.24	0.33	0.35	1	0.20	0.18	0.23	0.22	0.19
Female speakers	**6**	0.23	0.14	0.28	0.22	0.20	1	0.31	0.28	0.36	0.14
	7	0.22	0.10	0.24	0.20	0.18	0.31	1	0.27	0.30	0.15
	8	0.17	0.14	0.29	0.24	0.23	0.28	0.27	1	0.37	0.29
	9	0.21	0.16	0.33	0.26	0.22	0.36	0.30	0.37	1	0.21
	10	0.10	0.08	0.14	0.15	0.19	0.14	0.15	0.29	0.21	1
		With silence removal									
Male speakers	**1**	1	0.53	0.54	0.59	0.55	0.44	0.43	0.32	0.38	0.31
	2	0.53	1	0.56	0.61	0.55	0.43	0.35	0.40	0.45	0.36
	3	0.54	0.56	1	0.60	0.50	0.49	0.44	0.43	0.51	0.37
	4	0.59	0.61	0.60	1	0.57	0.50	0.46	0.46	0.51	0.43
	5	0.55	0.55	0.50	0.57	1	0.39	0.34	0.37	0.39	0.42
Female speakers	**6**	0.44	0.43	0.49	0.50	0.39	1	0.63	0.52	0.66	0.44
	7	0.43	0.35	0.44	0.46	0.34	0.63	1	0.50	0.58	0.42
	8	0.32	0.40	0.43	0.46	0.37	0.52	0.50	1	0.58	0.59
	9	0.38	0.45	0.51	0.51	0.39	0.66	0.58	0.58	1	0.51
	10	0.31	0.36	0.37	0.43	0.42	0.44	0.42	0.59	0.51	1

From the Table III, it can be noticed that the average spectral correlation of the different male speakers after applying silence removal is about 56% while for different female speakers is about 54%. The average correlation of the male-female part is about 42%. From this, it can be concluded that spectrums of the same gender are notably correlated, whilst spectrums of different gender are less

correlated. This can be explained by the fact that the energy of the audio origins from female speaker is concentrated around 200 Hz and 400 Hz, while energy for male speaker is distributed on larger frequency range. The average spectral correlation of all male speakers for the case without silence removal is about 30% and for all female speakers it is about 27%. These results confirm that the correlation decreases significantly because of the parts of the signal having a low energy (unsounded parts). These conclusions may be used for feature extraction in order to perform gender recognition using speech signal.

C. *Effect of Audio Signal Duration*

For the purpose of the audio signal duration effect investigation on the spectrum correlation, ten signals were prepared by concatenating all the uttered texts for each speaker. In such manner, each speaker is presented by a larger signal. The spectrum of this signal after silence removal is determined and the correlation between it and original signals is calculated. The results are shown in Table IV.

TABLE IV
CORRELATION BETWEEN SPECTRUMS OF SIGNALS SUM AND ORIGINAL ONES

	Speaker	Text1	Text2	Text3	Text4	Text5
All texts	**1**	0.77	0.75	0.81	0.72	0.70
	2	0.76	0.80	0.78	0.81	0.77
	3	0.81	0.73	0.75	0.76	0.76
	4	0.85	0.84	0.81	0.77	0.72
	5	0.73	0.79	0.67	0.81	0.80
	6	0.82	0.69	0.68	0.66	0.64
	7	0.79	0.78	0.71	0.80	0.68
	8	0.78	0.71	0.76	0.70	0.78
	9	0.81	0.68	0.75	0.79	0.70
	10	0.74	0.82	0.77	0.70	0.83

From the Table IV, it can be noticed that the correlation is enhanced using longer speech signal duration. Analyzing results from the Table I, it can be noticed that the average correlation between the different texts of the speaker 3 (with silence removal) is around 68%. On the other hand, the average correlation of the same speaker calculated based on Table IV is about 76%. From this, it can be concluded that if the audio signal is longer, the spectral correlation after silence removal is higher.

In order to support this conclusion, correlation matrices for each of the five analyzed texts and for all concatenated texts are calculated. From each obtained matrix, the average correlation between spectrums of male speakers (male vs. male), the average correlation between spectrums of female speakers (female vs. female) and the average correlation between speakers of different gender (male vs. female) are calculated. Referring to the Table III the male vs. male average correlation is computed based on the blue part of the table, while the orange part serves to calculate the female vs. female average correlation and the part in yellow is used to calculate the male vs. female correlation. Results of this analysis are presented in Fig. 3.

From the Fig. 3, it can be noticed that for higher duration of analyzed signal the spectral correlation between speakers is higher with silence removal than without it. Beside this, from this figure it can be concluded that spectral correlation after silence removal is higher to the speaker gender, while by comparing audio signals that origin from the speakers of different gender, it is concluded that the spectral correlation is lower. These results can be used for determination of the optimal speech recording duration in data training of speech analysis datasets.

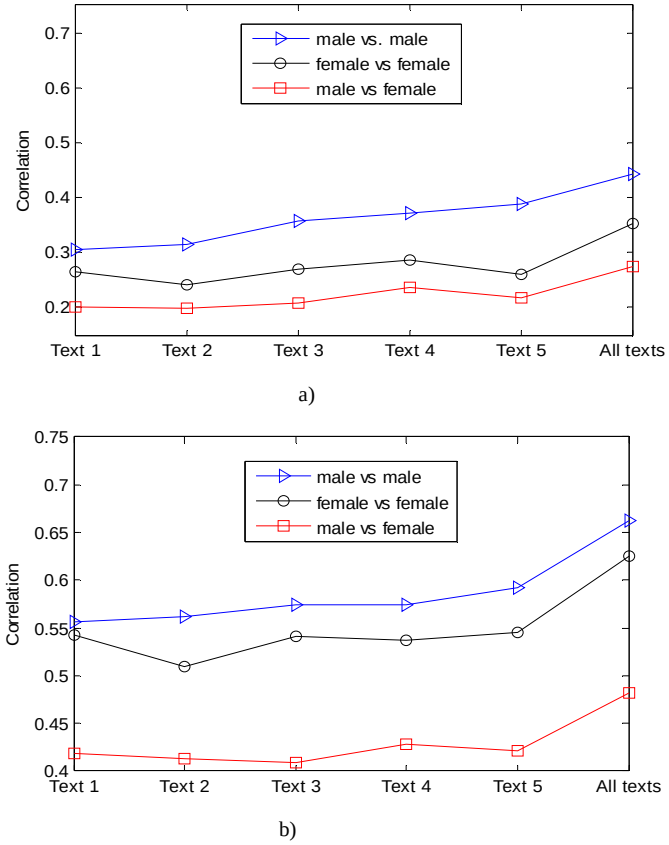

Fig. 3. Average correlation for the different texts and speaker gender: a) without silence removal and b) with silence removal.

IV. CONCLUSION

This paper presented a spectral analysis applied on recently created database that consists of male and female speech samples. Using the spectral correlation measure, in this research it is analyzed the effect of unsounded audio signal parts on the spectrum shape and it is shown that silent parts strongly affects the results of a spectral analysis. Beside this, in this research the spectrums obtained from signals of the same speaker for different uttered texts are compared and it is shown that they are strongly correlated. Moreover, there is a significant correlation between spectrums obtained from speakers of different gender reading the same text. In this research is also analyzed the

effect of the audio signal duration on the spectrum correlation. Obtained results show that for longer duration signal, the spectral correlation is higher. These results may be ground for future researches related to the speech signal analysis. In future research, the problem of spectral-based feature extraction for speaker identification will be considered. Furthermore, the case of background noise, music and distant speakers will be taken into account.

pyHRV: Development and Evaluation of an Open-Source Python Toolbox for Heart Rate Variability (HRV)

Pedro Gomes, Petra Margaritoff and Hugo Silva

***Abstract*—Heart Rate Variability (HRV) is a continuously growing field of interest in research, with an increasing number of new measurements being introduced over the recent decades, followed by complementary software tools. However, mostly closed source HRV tools are available, with high license costs and that prevent source code access for developers, limiting the possibilities of custom application development. Open-source solutions, on the other hand, face different limitations such as reduced functionality, non-validated results, or full support for mainstream programming languages. In this work, we describe a fully open-source Python toolbox named pyHRV for HRV in custom research and development applications, which is validated against a gold standard software. pyHRV computes state-of-the-art Time Domain (TD), Frequency Domain (FD), and Nonlinear (NL) HRV parameters. As for the evaluation, short-term parameters have been computed from 50 Normal-to-Normal Interval (NNI) series of 5 minutes in duration, with long-term parameters being computed from 50 NNI series of 60 minutes in duration. The results have been computed using the pyHRV toolbox and the KUBIOS HRV gold standard software, against which the pyHRV results have been compared. Overall, pyHRV computes a total of 78 HRV parameters (23 TD, 48 FD, 7 NL), from which 12 have achieved identical results as the gold standard software, 38 showing marginal and/or neglectable differences, and 26 showing significant differences, thus requiring further investigation.**

***Index Terms*—Heart Rate Variability, Python, Open-Source**

I. Introduction

Heart Rate Variability (HRV) has been established as a well known and important measure of cardiac and overall health, due to the extensive amount of research conducted over the past decades [1], [3], [4]. This is a continuously evolving research field in which series of temporal, spectral, and non-linear parameters are extracted from Inter-Beat-Interval (IBI) series, i.e. the intervals between successive heart beats, which has strongly benefited from the fast pace of technological advancements in the biomedical field [3], [18]. In addition, the advancements in consumer technology facilitated the access to tools with Heart Rate (HR) extracting capabilities, opening up new fields in which HRV can be found beyond the traditional clinical context, such as in pharmacology, sports science, and virtual reality applications [12], [16], [17], [19].

Many software solutions specialized in HRV have been published, motivated by its increasing research popularity and application fields providing researchers the necessary tools to support their research. However, solutions on both ends of the closed-source and open-source spectrum exhibit different shortcomings in their functionality, usability, or selection of extracted HRV parameters often limiting developers in their work towards new and custom software solutions. For instance, commercially available tools may often be well-established in research communities, but lack the insights in the underlying source code with little to no possibility to extract individual HRV algorithms for further integration possibilities. In addition, high-cost licenses are required to grant full access to all functionality of the software tools to researchers and developers. While open-source tools do not, in most cases, face the same limiting aspects of closed-source solutions, they do not always provide all features required for the computation of the most popular HRV features, have not been validated against gold-standard software, or lack support for mainstream programming languages.

The goal of this work is to validate the results of a newly developed open-source HRV toolbox for the Python programming language named pyHRV, to provide a reliable solution for HRV researchers and developers[1]. This toolbox complies with the HRV guidelines *"Heart Rate Variability: Standard of Measurement, Physiological Interpretation, and Clinical Use"* issued by the Task Force of The European Society of Cardiology and The North American Society of Pacing Electrophysiology in 1996 and newer findings in HRV research [1], [4], [18]. As for the evaluation, series of Normal-to-Normal Interval (NNI) datasets have been computed with the pyHRV toolbox and with KUBIOS HRV, here identified as the gold-standard software, compared, and evaluated to measure the reliability of the newly developed solution [20].

The remainder of the paper is organized as follows. The methods and materials are described in Section II. In Section III, the experimental results are presented to illustrate the performance of the proposed toolbox. Finally, conclusions and future work are discussed in Section IV.

II. Methods and Materials

A. HRV Parameters Computable with pyHRV

pyHRV computes TD and FD parameters in accordance with the HRV guidelines and latest findings in HRV research, adding also newer methods for the extraction of NL parameters [1], [3], [4], [6]. In the TD, temporal statistical parameters are derived from the NNI series, Series of Successive NNI Differences (ΔNNI), and HR series. Table I lists all computable TD parameters using pyHRV. In the FD, all spectral parameters are computed from Power Spectral Density (PSD) estimation methods computed from the NNI series. The Fast Fourier Transform (FFT)-based Welch's and the Autoregressive (AR) methods have been implemented according to the HRV guidelines, with the selection of available PSD methods being extended by the Lomb-Scargle method [1], [7]–[9].

Table II lists all computable FD parameters which can be computed over up to 4 frequency bands, the Ultra Low Frequency (ULF), Very Low Frequency (VLF), Low Frequency (LF), and High Frequency (HF) band. Default frequency ranges are defined for the VLF (0.00Hz-0.04Hz), LF (0.04Hz-0.15Hz), and HF (0.15-0.40Hz) bands [3].

The guidelines failed to establish a standard set of nonlinear methods and parameters, due to the lack of scientific backing for the variety of suggested methods at the time [1]. The Poincaré scatter plot is a commonly found visualization method of HRV, from which a set of parameters can be derived: the Standard Deviation (SD) along the minor axis of the scatter plot (SD1), the SD along the major axis (SD2), the SD2/SD1 ratio, and the area of a fitted ellipse with the focal points SD1 and SD2 along the minor and major axis [3], [6]. In addition, the set of NL parameters has been extended by the Sample Entropy (SamPen) and the Detrended Fluctuation Analysis (DFA) [4]. The computable NL parameters are listed in Table III.

B. Open-Source Third-Party Python Packages

The BioSPPy (v.0.5.1) packages *biosppy.signals.ecg.ecg()* function is used in pyHRV to extract R-peak locations from ECG signals, which are required for the computation of the NNI series, from which the HRV parameters are subsequently computed. Different packages have been used for the computation of the different methods of PSD estimations. The *scipy.interpolate.interp1d()* and the *scipy.signal.welch()* functions of the SciPy package (v.1.1.0) are used for the 4Hz interpolation of the NNI series and the computation of the Welch's PSD. Additionally, the *scipy.signal.lombscargle()* method is used for the computation of the Lomb-Scargle method. The AR PSD is computed using the Yule-Walker algorithm of the Spectrum package (v.0.5.2) using the *spectrum.pyule()* function. The NL parameters, the SamPen and the DFA are computed using the *nolds.sampen()* and the *nolds.dfa()* functions from the nolds (NOnLinear measures for Dynamical Systems) (v.0.4.1) package. All functions with plotting capabilities use the Matlplotlib (v.2.2.2) plotting library. Data series and their manipulation are stored and conducted in the NumPy (v.1.15.1) array format and its supported functionalities. Other Python native packages are used through pyHRV for general purpose functions such as data import and export, time stamp creation, and operating system-specific functionalities. All functions are used, configured, and extended with HRV application-specific input parameters, ranges, and methods [1].

C. NNI Series Used for the Evaluation Procedure

The NNI series used is the MIT-BIH Normal Sinus Rhythm Database (MIT-BIH) from the PhysioNet database [2]. This database consists of long-term ECG recordings from 18 healthy subjects (5 men, 26 to 40 years and 13 women, 20 to 50 years) with no observable pathological ECG arrhythmias. The NNI series were extracted directly from the PhysioBank ATM (Automated Teller Machine). The use of

the NNI series as input data is preferred over the use of the raw ECG signals to avoid HRV parameter computation using non-identical input data series, as differences could occur due to the different implementations of the R-peak detection algorithms in BioSPPy and KUBIOS HRV. Such differences could ultimately influence the parameter results (pyHRV vs. KUBIOS HRV).

D. NNI Pre-Processing and HRV Parameter Computation

Although the physiological context and significance of the computed HRV parameters are not of interest for the evaluation process, all efforts were made to provide physiologically reasonable data and HRV input parameters. The NNI series of the MIT-BIH database contain NNI outliers of up to approx. 42 seconds in duration. These outliers are caused by visible motion artifacts and/or electrode disconnections during the acquisition rather than having a physiological source, and are visible the original ECG datasets, distorting the NNI series as depicted in the Tachogram shown in Figure 1. This could greatly alter the signal segmentation process in the next steps and the HRV parameter results, reason for which these outliers have been removed by applying a threshold of 1.2s ($\hat{=}$ 50 bpm) as maximum acceptable NNI duration.

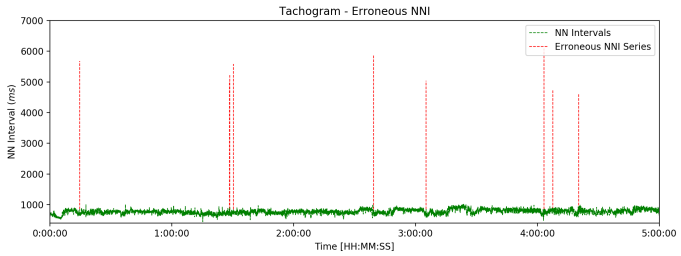

Fig. 1. Tachogram of a NNI series with outliers caused by signal artifacts during the ECG acquisition (in red). These outliers can cause issues during the signal segmentation process of the NNI series pre-processing and eventually alter the results of the HRV parameters (signal source: MIT-BIH, signal 19090 [2]).

After applying the 1.2s threshold, the original NNI series were segmented into multiple blocks of shorter durations, resulting in segments with 5 minute duration for the computation of short-term parameters and 60 minute segments for the computation of the long-term parameters SDNN Index and SDANN. The algorithms computing these long-term parameters contain their own segmentation process, which splits the 60 minute segments into 12 $\times$ 5 minute segments, reason for which additional datasets have been generated to validate these parameters. From all generated segments, 50 x 5 minute and 50 $\times$ 60 minute segments have been randomly selected from which HRV parameters were computed using pyHRV and KUBIOS HRV according to the configurations listed in Table IV.

E. Classification and Validation of the HRV Results

The following statistical taxonomy has been applied to classify the pyHRV results into three categories: *Optimal*, *Acceptable*, and *Divergent*. The mean values $\overline{P_x}$ and $\overline{K_x}$, and the standard deviations (SD) $\sigma(P_x)$ and $\sigma(K_x)$ have been computed for both the pyHRV (P_x) and KUBIOS (K_x) results, with x being one of the computed HRV parameters. In addition, the absolute difference Δ_x between $\overline{P_x}$ and $\overline{K_x}$ values have been computed. The entire pre-processing, parameter computation, and evaluation process is illustrated in Figure 2. Depending on these parameters, the performance of the pyHRV parameters have been classified as follows:

TABLE IV
PYHRV & KUBIOS PARAMETER SETTINGS.

Parameter Settings	
Parameter Specific Settings	Set Value(s)
NNI detrending method	None[k]
HR parameters computed as average of X heart beats	1 beat[k]
VLF Frequency Band	0.00 Hz - 0.04 Hz
LF Frequency Band	0.04 Hz - 0.15 Hz
HF Frequency Band	0.15 Hz - 0.40 Hz
FFT - Interpolation frequency	4 Hz
FFT - Window width	300 s
FFT - Window overlap	50 %
Lomb - Smoothing	None[k]
AR - Model order	16
Sample Entropy - Embedding dimension	2
Sample Entropy - Tolerance	0.2 · SD
DFA - Short term fluctuations	4 - 16 beats
DFA - Long term fluctuations	17 - 64 beats

[k] KUBIOS HRV specific parameter settings only.

Optimal: $\Delta_x = 0$
The computed parameter results are exact. No difference exists between $\overline{P_x}$ and $\overline{K_x}$.

Acceptable: $0 < |\Delta_x| \leq \sigma(K_x)$
The computed parameter results have a difference Δ_x between $\overline{P_x}$ and $\overline{K_x}$ which is $\leq \sigma(K_x)$. Differences within 1 SD of $\overline{K_x}$ are considered non-significant and, therefore, acceptable.

Divergent: $—\Delta_x| > \sigma(K_x)$
The computed parameter results are not identical and have a significant difference Δ_x. These results need further analysis.

III. MAIN RESULTS

A. Time Domain Results

The TD results are presented in Table V. Overall, 10 of the 11 comparable results lie within the optimal and acceptable ranges, with the Triangular Interpolation of the NNI Histogram (TINN) parameter being the only divergent parameter. The TINN's difference between the means is almost twice as high as the KUBIOS mean result with pyHRV's mean value at roughly only a third of the KUBIOS mean ($\sigma(K_{TINN}) = 104.915\ ms$ vs. $|\Delta_{TINN}| = 19.4887\ ms$), thus showing a significant difference. Although KUBIOS does not return the N and M values of the TINN parameter computation, it can be assumed that these parameters are also divergent given that they are the base parameters for the computation of the TINN parameter.

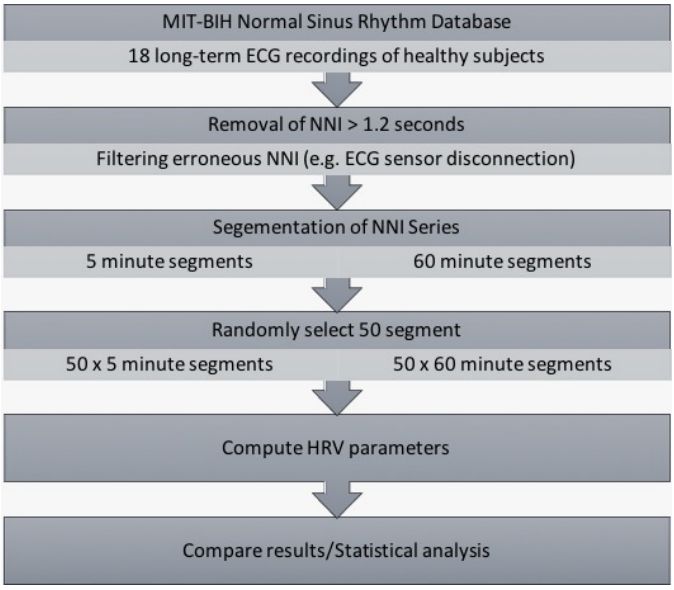

Fig. 2. NNI series pre-processing and evaluation procedure.

The mean of the NNI, minimum HR, SDNN, NN50, and pNN50 parameter results show optimal performance being identical to the KUBIOS results. It can be assumed that the non-compared NN20 and pNN20 parameters also achieve optimal results given that these parameters are computed by the same fundamental function as the NN50 and pNN50 parameters ($tools.time\_domain.nnXX()$). The mean HR ($\sigma(K_{\overline{HR}}) = 13.422\ bpm$ vs. $|\Delta_{\overline{HR}}| = 0.552\ bpm$), SDNN index ($\sigma(K_{SDNNI}) = 17.352\ ms$ vs. $|\Delta_{SDNNI}| = 0.320\ ms$), Standard Deviation of the Mean of NN Intervals in all 5 minute Segments (SDANN) ($\sigma(K_{SDANN}) = 19.331\ ms$ vs. $|\Delta_{SDANN}| = 0.716\ ms$), and the Triangular Index ($\sigma(K_{TRI}) = 3.886$ vs. $|\Delta_{TRI}| = 0.342$) lie within acceptable limits, with the RMSSD ($\sigma(K_{RMSSD}) = 22.611\ ms$ vs. $|\Delta_{RMSSD}| = 0.001\ ms$) being close to the values computed by KUBIOS, with a marginal difference of $0.001\ ms$.

B. Frequency Domain Results

The FD parameters computed from the Welch's method are presented in Table VI, and show overall optimal and acceptable results. pyHRV's peak frequencies in each frequency band are identical to the results obtained with KUBIOS. Differences can be found for the rest of the parameters, although marginal, given that the mean results exist within the acceptable range.

The FD parameters computed from the Lomb-Scargle method are presented in Table VIII. The evaluation results of this method identify half of the parameters within acceptable ranges, with the other half providing divergent results. No optimal results are computed by pyHRV. The Peak Frequencies show acceptable results for the VLF ($\sigma(K_{VLF,Peak}) = 0.009\ Hz$ vs. $|\Delta_{VLF,Peak}| = 0.006\ Hz$) and HF ($\sigma(K_{HF,Peak}) = 0.066\ Hz$ vs. $|\Delta_{HF,Peak}| = 0.063\ Hz$) with the LF results being divergent due to a greater difference than the KUBIOS results ($\sigma(K_{LF,Peak}) = 0.019\ Hz$ vs. $|\Delta_{LF,Peak}| = 0.028\ Hz$). Other acceptable results could be achieved for the Absolute Powers in all Frequency Bands (FB), the Total Power, and the Relative and Logarithmic Powers in LF band. The remaining parameters are divergent, therefore requiring further investigation. It is worth mentioning that no consistency over FB-specific results can be observed. For instance, the Absolute Powers provide acceptable results in the VLF and HF band. However, parameters derived from these parameters (Log. Powers and Relative Powers) show divergent results in these bands. This inconsistency influences additional parameters which depend on the Absolute Powers of the HF band (LF/HF ratio and Normalized Powers), leading to the divergent results.

The evaluation results of the Autoregressive parameters are presented in Table VII. Overall the results of 6 parameters lie within acceptable ranges, with 10 parameter results being divergent due to differences greater than 1 SD of the KUBIOS results. The Peak Frequencies lie within acceptable ranges for every FB. Other acceptable parameter results were computed for the Absolute Powers ($\sigma(K_{VLF,Abs}) = 2666.353\ ms^2$ vs. $|\Delta_{VLF,Abs}| = 645.599\ ms^2$), and Log. Powers ($\sigma(K_{VLF,Log}) = 0.978\ ms^2$ vs. $|\Delta_{VLF,Log}| = 0.742\ ms^2$) of the VLF band, as well as the Relative Powers of the LF frequency band ($\sigma(K_{LF,Rel}) = 14.716\ \%$ vs. $|\Delta_{LF,Rel}| = 6.466\ \%$). However, all remaining results lie outside the 1 SD limits considered to be acceptable. It should be noted that, overall the Absolute Powers, with the exception of the VLF band, are significantly higher and lie multiple SD apart from the KUBIOS results, being almost 4.3 times higher in the LF band ($\sigma(K_{LF,Abs}) = 1137.171\ ms^2$ vs. $|\Delta_{LF,Abs}| = 4858.550\ ms^2$) and 8 times higher in the HF band ($\sigma(K_{HF,Abs}) = 1455.146\ ms^2$ vs. $|\Delta_{HF,Abs}| = 11512.643\ ms^2$).

C. Nonlinear Parameter Results

The evaluation results for the Nonlinear parameters are listed in Table IX. Overall, the 7 comparable parameters provide acceptable results, with the SD2/SD1 ratio showing even optimal results. Marginal differences are present for the SD1 ($\sigma(K_{SD1}) = 16.015\ ms$ vs. $|\Delta_{SD1}| = 0.044\ ms$) and SD2 ($\sigma(K_{SD2}) = 35.962\ ms$ vs. $|\Delta_{SD2}| = 0.123\ ms$) parameters, with the Sample Entropy results achieving almost optimal results ($\sigma(K_{SamPen}) = 0.366$ vs. $|\Delta_{SamPen}| = 0.001$). The highest relative differences are present in the results of the DFA α_1 ($\sigma(K_{\alpha 1}) = 0.240$ vs. $|\Delta_{\alpha 1}| = 0.022$) and α_2 ($\sigma(K_{\alpha 2}) = 0.199$ vs. $|\Delta_{\alpha 2}| = 0.047$) parameters. The area of the fitted ellipse in the Poincaré plot could not be compared, as this parameter is not computed by KUBIOS. However, given that this parameters is computed based on a multiplication of the SD1 and SD2 parameters with π, and considering that these parameters have low relative differences, it can be assumed that it would also lie within acceptable limits.

IV. Conclusion

In the TD, the only concern lies within the computation of the TINN parameters, where significant differences could be identified. A thorough revision of the TINN algorithm is required for future versions of pyHRV. In the FD, no

Δ: Difference between pyHRV and KUBIOS mean value

immediate improvements are required for the PSD estimation using the Welch's method, given that the implemented algorithm did correctly identify the peak frequencies of the PSD which are a critical piece of information of the PSD. The remaining 16 extracted parameters show acceptable deviations from the KUBIOS HRV results. The PSD estimation using the Autoregressive method shows acceptable results for 6 out of 16 parameters, with the peak frequencies being also identified with acceptable deviations. The remaining parameters show significant differences in comparison with the KUBIOS HRV results, which can be caused by the selected AR estimation and parameter computation algorithms, in our case on the Yule-Walker algorithm. Higher power estimations can be observed over all computed NNI datasets compared to the KUBIOS HRV estimations. This does greatly alter the absolute powers of the different FB, from which the remaining parameters are extracted and ultimately distorted. For this method, the use of other algorithms or methods can be considered to be further research in order to improve the performance of the implemented algorithms. The Lomb-Scargle PSD estimation achieved 8 parameters lying within acceptable ranges, with the remaining 8 parameters showing significant differences. Other than with the previous PSD estimation methods, this method has shown high sensitivity in the selection of a suitable frequency resolution, which leads to inconsistency and significant changes in its capability of identifying the correct peak frequencies of the PSD. This method failed to accurately identify the peak frequencies of the LF band, critical information of the PSD while identifying these frequencies in the remaining bands with acceptable accuracy. However, this inconsistency can be observed over the results of all the remaining parameters, where the results of different parameters with significant differences can be observed over different FB. With the current version, the selection of a suitable frequency resolution lies

therefore within the responsibility of the user and the intended application. The comparison of the NL parameters have shown positive results, with 6 out of 7 parameters showing acceptable results, and only marginal differences found when compared to

the KUBIOS results, and the SD2/SD1 ratio achieving optimal results. The functions of this module do not require any further optimization.

In addition to the results discussed in the previous section, which require further revision and improvements in some parameter computation functions of the TD and FD, the developed pyHRV toolbox will experience continued development with the implementation of new HRV methods and features in the future. For example, Björkander et al. [11] have proposed a new geometrical TD parameter named the Differential Index, which is composed based on the NNI histogram from which the geometrical parameters are derived. This parameter is computed from long-term Electrocardiography (ECG) recordings to visualize and extract parameters from NNI series with 10.000 and more intervals without the need for heavy computational algorithms. For the FD, German-Sallo [10] has investigated the use of a Wavelet Package Transform as an alternative method to compute the FFT based PSD estimation method, to measure the power variance and to identify dominant frequencies in a NNI series. His approach has shown good time-frequency resolution and comparable results for the LF/HF ratio, however, it still requires further investigation. It is also worth considering other features for deriving additional data series directly from the ECG signal, such as the ECG Derived Respiration (EDR) algorithm, where respiration data can be derived from the cardiac activity [14]. Although such features do not provide additional HRV parameters, they do provide other interesting measures that are often found in cardiac activity research [12], [13], [15].

A Solution of Concurrent Stack on PSTM

Marko Popovic, Branislav Kordic, Miroslav Popovic, Ilija Basicevic

***Abstract*—Nowadays developing concurrent data structures based on foundations of software transactional memory (STM), a.k.a. transactional data structures, is an area of intensive research. In this paper, we developed the concurrent stack on Python STM (CS-PSTM), and verified it using unit and system testing. For system testing we developed the five application workloads, namely: one producer - one consumer, nP producers, nP consumers, nP producers and nC consumers, and nP processes. The CS-PSTM successfully passed all of the unit and the system tests. We also used system tests to estimate CS-PSTM performance. Interestingly, and not unexpectedly, CS-PSTM provides better performance when used by more concurrent processes.**

***Index Terms*— multicore systems; parallel programming; Python; transactional memories; concurrent data structures; concurrent stacks.**

I. Introduction

SINCE the emergence of multicore processors, many efforts have been dedicated to building concurrent data structure libraries (CDSLs) [1, 2], which are a.k.a. thread-safe libraries. Efficient CDSL implementations are available for many programming languages, as C++, Java, C#/.NET, TBB, Python, etc., and are widely adopted [3]. These state-of-the-art CDSLs are implemented using locks and/or atomic instructions such as CAS.

In 1993 Herlihy and Moss introduced the idea of the *transactional memory* (TM) [4], in order to overcome difficulties related to lower-level abstraction based on locks. The concept of TM has the following two main advantages over locks: (1) TM makes parallel programming easier by supporting abstraction and composition, and (2) TM based parallel programs tend to have better performance than traditional *lock* based programs because individual transactions are executed *optimistically* [5].

Software TMs (STMs) enabled research and development of new type of concurrent data structures based on STMs. One notable example of this is development of lock-free (concurrent) data structures using STM in Haskell [6]. Similarly, we in our previous research followed this path to design and implement a concurrent list [7] and concurrent queue [8] based on particular software TM (STM) in Python, named PSTM [9]. Nowadays developing concurrent data structures based on foundations of software transactional memory (STM), a.k.a. transactional data structures, is an area of intensive research [10, 11].

Along these lines of research, this paper makes its main contribution by presenting the solution for a concurrent stack based on PSTM, which we briefly refer to as the concurrent stack on PSTM (CS-PSTM). CS-PSTM is based on the unbounded lock-free stack using CAS [1] (pp. 245, 247).

We verified CS-PSTM using unit and system testing. For unit testing we developed nine test cases, whereas for system testing we developed five application workloads. These application workloads are the following: (1) one producer - one consumer workload, (2) *nP* producers workload, (3) *nP* consumers workload, (4) *nP* producers and *nC* consumers workload, and (5) *nP* processes workload. The CS-PSTM successfully passed all of the unit and the system tests.

We also used system tests to estimate CS-PSTM performance. Interestingly, and not unexpectedly, CS-PSTM provides better performance when used by more concurrent processes, but of course not above the number of available cores (which was four in this research).

One important advantage of the CS-PSTM design is that it may be easily adapted to be used in distributed settings. The key idea in the design of CS-PSTM that enable this adaptation is that stack elements are linked together using t-var identifications, which are strings.

The rest of the paper is organized as follows. Section II introduces the sequential stack, Section III presents the concurrent stack on PSTM (CS-PSTM), Section IV presents the unit and system testing, and Section V presents the final conclusions of this paper.

II. Sequential Stack

In this section we briefly introduce the definition of a sequential stack, which originates from [8] (pp. 245). A *sequential stack Stack<T>* is an ordered sequence of items of a type *T*, which provides the following two methods: (i) the method *push*(*x*) puts an item *x* at the *top* of the queue, (ii) the method *pop*() removes and returns the item from the *top* of the stack.

A sequential stack is implemented as a linked list of nodes. A *node* is a data structure, which comprises the following two fields: (i) the field *item* is the actual item of interest (the variable *x* mentioned above), and (ii) the field *next* is a link to the next node in the list, which is null if that is the last node in the list.

The list consists of regular nodes, where each node contains

Miroslav Popovic, University of Novi Sad, Faculty of Technical Sciences, Novi Sad, Trg Dositeja Obradovica 6, 21000 Novi Sad, Serbia (e-mail: miroslav.popovic@rt-rk.uns.ac.rs).

Ilija Basicevic, University of Novi Sad, Faculty of Technical Sciences, Novi Sad, Trg Dositeja Obradovica 6, 21000 Novi Sad, Serbia (e-mail: ilija.basicevic@rt-rk.uns.ac.rs).

a stack's item, and the link to the next node. Unlike similar concurrent data structures, such as concurrent lists and queues, there is no need for some special nodes (e.g. sentinels). The list that implements the concurrent stack is organized by a single pointer, *top*, which points to the node at the top of the stack.

Initially, the stack is empty, thus *top* contains the null pointer, see Fig. 1a. The method *push*(*a*) adds the item *a* at the *top* of the stack, see Fig. 1b. The method *pop*() removes and returns the item *a* from the top of the stack, if the stack is not empty; otherwise it indicates that the stack is empty. For example, when the method *pop*() is called on the stack shown in Fig. 1b, it sets *top* to null pointer, and returns the item *a*. The result of this *pop*() is the same as the initial stack shown in Fig. 1a.

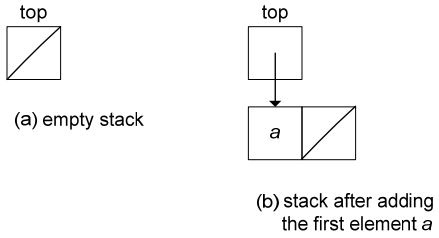

Fig. 1. Stack implemented as a linked-list.

The next section presents the CS-PSTM, which is linearizable to a sequential stack.

III. Concurrent Stack on PSTM

The concurrent queue on PSTM is based on the definition unbounded lock-free stack [8] (pp. 245, 247) and on the previously developed PSTM [3].

A. Short Overview of PSTM

The PSTM is client-server architecture [9]. The client consists of the STM-based application and the set of API functions (defined in the PSTM module) that act as a client's proxy. The PSTM server serves requests created by PSTM API functions and sent over the queue to the server. The queue connects multiple clients (transactions) with a single server. Replies from the server to clients are sent over pipes. A pipe connects the server with a single client.

The PSTM server is the owner of the system *dictionary* that contains current entries for all the t-variables (t-vars) used by transactions. The *dictionary item* is a tuple (*key*, *ver*, *val*), where *key* is the t-var key (aka t-var identification, ID), *ver* is the current t-var version, and the *val* is the current t-var value. The PSTM server serves incoming requests atomically.

The main PSTM API functions are the following:

1. *addVars*(*q*, *keys*)
2. *getVars*(*q*, *keys*)
3. *putVars*(*q*, *vars*)
4. *commitVars*(*q*, *read_write*)

Where *q* is a queue between clients and PSTM server, *keys* is a list of t-variable's IDs, *vars* is a list of dictionary items, and *read_write* is the list <*read*, *write*> where *read* and *write* are lists of items that a transaction reads and writes (updates), respectively. The function *getVars* returns the list of tuples (*exists*, (*ver*, *val*)), where *exists* is True if t-var is found, or False otherwise. Other functions return 'no' if an error occurs, or 'yes' otherwise.

A transaction typically gets its local copies of t-vars using *getVars*, does some processing with them, and finally updates some of them using *commitVars*. New t-vars are added and initialized by *addVars* and *putVars*, respectively.

B. Concept and Data Structures and API Functions

The concurrent stack on PSTM is created by putting the nodes into t-vars and linking them using t-var identifications. The advantage of this solution is that it may be easily adapted for a distributed setting, because t-vars need not be located in the same computer. Next, we describe data structures that are used to implement the concurrent stack on PSTM.

The stack on PSTM and its nodes are represented as Python named tuples *StackOnPSTM* and *Node*, respectively. The elements of the named tuple *StackOnPSTM* are: the name of the stack (*stackName*) and the *top* of the stack t-var identification (*topTvarId*)). The elements of the named tuple *Node* are: the item (*item*) and the t-var identification of the next element in the stack on PSTM (*next*).

Two types of t-vars are used to implement the stack on PSTM. The t-var of the first type contains the t-var identification of the top of the t-vars stack, whereas the t-vars of the second type contain stack's nodes. The t-var *top* is the t-var of the first type, whereas the nodes containing the items are the t-vars of the second type.

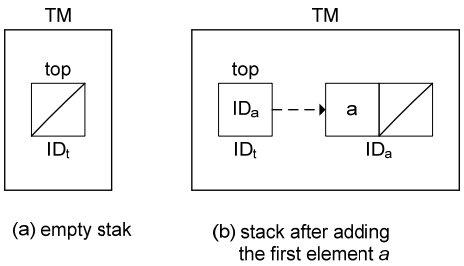

Fig. 2. Stack on PSTM.

Fig 2a shows the empty stack, which consists of the *top* placed into a t-var (in TM) with the identification ID_t. Since the stack is empty, *top* contains the null pointer. Fig 2b shows the stack after the first item *a* is pushed at its top. The item *a* is stored in the t-var with the identification ID_a, and the *top* is updated to point to the node with the item *a*.

The API functions are the following: *createStackOnPSTM*(*q*, *stackName*), *push*(*q*, *S*, *item*), and *pop*(*q*, *S*).

C. The function createStackOnPSTM

At the beggining, the function sets *top* t-var identification, *topTvarId*, by concatenating the stack name parameter, *stackName*, with the string 'topTvarId'.

Then, it uses the PSTM API function *addVars* to add the t-var *topTvarId* to PSTM transactional memory.

After that, it uses the PSTM API function *putVars* to set the identification of the t-var at the top of the stack, to its initial value null pointer, which is encoded as the empty string ''.

At the end, the function returns the instance of the tuple *StackOnPSTM* representing the new stack, which is set to the value (*stackName*, *topTvarId*).

D. The function push

The pseudocode for the function *push* is given in Algorithm 1. At the beginning, the function calls the PSTM API function *createVar* in order to create the new t-var for the new item, and stores the identification of the new t-var in the variable *nodeTvarId* (lines 2 – 3). Then in the endless loop, it calls the supplementary function *tryPush*, which in its turn tries to effectively perform the required push operation (lines 4 – 6). Once the function *tryPush* succeeds to push item on the stack, it returns **True**, and the function *push* returns (line 6).

The function *tryPush* begins by creating the empty read and write lists of t-var PSTM items, *readList* and *writeList*, respectively (lines 8-9). A *t-var PSTM item* is a tuple comprising t-var's identification, its version, and its value [3]. After that, it initializes the read-write list (*readWriteList*) with its elements – *readList* and *writeList* (line 10).

Then it sets the variable *topid* to the identification of the t-var *top* (line 12), and calls the function *getTvarVerAndValue* to get the value (*top*) and the PSTM item (*top_item*) for the t-var *top* (line 13). Next, it unpacks the tuple *top_item* to the variables *tid*, *tver*, and *tval*, holding the *top*'s ID, version, and value, respectively (line 14).

After that, the function creates a new node (*node*) using the argument *item* and links the new node with *top* (line 16). Then, it creates the t-var item for the new node (*node_item*) consisting of the *nodeTvarId*, version value 0, and *node*, and appends it to the write list (lines 18-19).

In order to update the t-var *top*, such that it points to the new node, the function creates the new PSTM item (*new_top_item*) from variables *tid*, *tver*, and *nodeTvarId* (line 21), and then appends *new_top_item* to *writeList* (line 22).

Finally, the function calls the API function *commitVars* to update t-vars as specified by *readWriteList*. If the commit is successful, the function returns **True**; otherwise, it returns **False** (lines 24 – 28).

Algorithm 1. The function *push*

```
01: push(q, S, item)
02:   ret ← createVar(q)
03:   nodeTvarId ← ret[0]
04:   while True
05:     if tryPush(q, S, item, nodeTvarId) then
06:       return

07: tryPush (q, S, item, nodeTvarId)
08:   readList ← []              // initialize read list
09:   writeList ← []             // initialize write list
10:   readWriteList ← [readList, writeList]
11:   // Get the top
12:   topid ← S.tvarIdTop
13:   top, top_item ← getTvarVerAndValue(q, topid)
14:   (tid, tver, tval) ←  top_item
15:   // Create the new node and link with current top
16:   node ← Node(item, top)
17:   // Create node_item and add it to write list
18:   node_item ← (nodeTvarId, 0, node)
19:   writeList.append(node_item)
20:   // Create new_top_item and add it to write list
21:   new_top_item ← (tid, tver, nodeTvarId)
22:   writeList.append(new_top_item)
23:   // Do the Commit
24:   ret ← commitVars(q, readWriteList)
25:   if ret = ['yes'] then
26:     return True
27:   else
28:     return False
```

E. The function pop

The pseudocode for the function *pop* is given in Algorithm 2. The function *pop*, in the endless loop, calls the supplementary function *tryPop*, which in its turn tries to effectively perform the required pop operation (lines 2 – 5). If *tryPop* finds that stack is empty, it returns None. Otherwise, it returns the popped item (*retItem*), which in its turn the function *pop* returns to its caller.

The function *tryPop* begins by creating the empty read and write lists of t-var PSTM items, *readList* and *writeList*, respectively (lines 7 – 8). After that, it initializes the read-write list (*readWriteList*) with its elements – *readList* and *writeList* (line 9).

Then it sets the variable *topid* to the identification of the t-var *top* (line 11), and calls the function *getTvarVerAndValue* to get the value (*top*) and the PSTM item (*top_item*) for the t-var *top* (line 12).

It then checks whether the stack is empty, and if yes, it returns the value None (lines 14-15). If not, it unpacks the tuple *top_item* to the variables *tid*, *tver*, and *tval*, holding the *top*'s ID, version, and value, respectively (line 17).

Then, it gets the *node* and the *node_item* from the top of the stack (line 19). It then unpacks the triple *node_item* to the variables *nodeid*, *nodever*, *nodeval*, respectively (line 20). Then, it tries to set the variable *newTop* to the value of the field *next* of the node at top of the stack (*node*). This is done within the **try-except** construct, because meanwhile *node* may be deleted by another process, in which case the function returns the value None (lines 22-23).

If *newTop* is set successfully, the function adds the *node_item* to the *readList* (line 26).

In order to update the t-var *top*, such that it points to the node after the node that is going to be popped, the function creates the new top PSTM item (*new_top_item*) from variables *tid*, *tver*, and *newTop* (line 28), and then appends *new_top_item* to *writeList* (line 29).

Finally, the function calls the API function *commitVars* to update t-vars as specified by *readWriteList*. If the commit is successful, the function returns *item* (from *node*); otherwise, it returns the value None (lines 31 – 37).

Algorithm 2. The function *pop*

```
01: pop(q, S)
02:   while True
03:     retItem ← tryPop(q, S)
04:     if retItem ≠ None then
05:       return retItem

06: tryPop(q, S)
07:   readList ← []              // initialize read list
08:   writeList ← []             // initialize write list
09:   readWriteList ← [readList, writeList]
10:   // Get the top
11:   topid ← S.tvarIdTop
12:   top, top_item ← getTvarVerAndValue(q, topid)
13:   // If stack is empty, return item None
14:   if top = '':
15:     return None
16:   // Unpack the top_item
17:   (tid, tver, tval) ← top_item
18:   // Get node and node_item from top of the stack
19:   node, node_item ← getTvarVerAndValue(q, top)
20:   (nodeid, nodever, nodeval) ← node_item
21:   // Set newTop to node.next
22:   try newTop ← node.next
23:   except return None
24:   // Prepare read-write list for the commit
25:   // Add node_item to readList
26:   readList.append(node_item)
27:   // Create new item for top and add it to writeList
28:   new_top_item ← (tid, tver, newTop)
29:   writeList.append(new_top_item)
30:   // Do the Commit
31:   ret ← commitVars(q, readWriteList)
32:   if ret = ['yes'] then
33:     // Remove t-var containing node
34:     removeVars(q, [nodeid])
35:     return node.item
36:   else
37:     return None
```

IV. Unit and System Testing

We verified CS-PSTM using unit and system testing. For unit testing we developed nine test cases, whereas for system testing we developed five application workloads. The CS-PSTM successfully passed all of these unit and system tests.

For unit testing we used the following test cases: (1) create single CS-PSTM stack, (2) create multiple CS-PSTM stacks (100 stacks), (3) push a single item on the CS-PSTM stack, (4) enqueue multiple (100) items on the CS-PSTM stack and check its length using the internal function *length*, (5) try to pop a non-existing item from the empty CS-PSTM stack, (6) pop an existing item from the CS-PSTM stack with one item, (7) create a child process and check whether the child process successfully pushed a single item (by checking pop from the stack), (8) create a child process, push a single item on the stack, and check whether the child process successfully dequeues that item, (9) push multiple (100) items on the CS-PSTM stack, pop the first half of the items (50), and check whether the second half of the items (50) remains on the CS-PSTM stack using the internal function *length*.

For system testing we used the following application workloads (which all start from the empty CS-PSTM stack, except NC which starts from the stack with *nItem* items): (1) the one producer - one consumer (OPOC), where producer and consumer exchange *nItems* items over the stack in the two possible modes, namely the sequential mode (where producer and consumer are executed sequentially) and the parallel mode (where producer and consumer are executed in parallel), (2) *nP* producers (NP), where each producer pushes *nItems*/*nP* items onto the stack, (3) *nP* consumers (NC), where each consumer consumes *nItems*/*nP* items from the stack, (4) *nP* producers and *nC* consumers (NPNC), where each producer produces *nItems*/*nP* items onto the stack, and each consumer consumes *nItems*/*nC* items from the stack, and (5) *nP* processes (NPP), where each process produces *nItems* onto the stack and then consumes *nItems* from the stack.

TABLE I. Overview of System Tests

Application Workload		Exe. Time [s]
OPOC	Sequential	0.3619
	Parallel	0.2464
NP	*nP* = 2	0.176
	nP = 3	0.1686
	nP = 4	0.1671
NC	*nP* = 2	0.2152
	nP = 3	0.2189
	nP = 4	0.2137
NPNC	(*nP*, *nC*) = (1, 2)	0.2722
	(*nP*, *nC*) = (1, 3)	0.2695
	(*nP*, *nC*) = (2, 2)	0.2718
	(*nP*, *nC*) = (2, 1)	0.2907
	(*nP*, *nC*) = (3, 1)	0.2934
NPP	*nP* = 2	0.3066
	nP = 3	0.2827
	nP = 4	0.2583

We conducted system testing using the Intel Core i7-8700 CPU @ 3.2 GHz six core processor with 16GB of shared memory. Our goal was to expose the CS-PSTM to maximal concurrency by running child processes within the workloads on separate processor cores. Since at least one of the cores must be reserved for the operating system and one for the PSTM server, the number of child processes in the workloads had to be up to 4 (we used 1, 2, 3 or 4).

Next, we introduce the application parameters. The parameter *nItems* is the number of items to be transferred over the stack, and is set to 99 (in OPOC) or 120 (otherwise, to make it divisible by the number of child processes). For the applications NP, NC, and NPP, the parameter *nP* is the total number of child processes, and is set to 2, 3 or 4.

For the application NPNC, the parameter *nP* is a number of

producers, whereas *nC* is a number of consumers, and these two parameters are set together as a pair (*nP*, *nC*) to pairs of values (1, 2), (1, 3), (2, 2), (2, 1) or (3, 1), because there were 4 cores available so the sum of *nP* and *nC* must be equal to 4.

The overview of system tests is given in Tab. I. The primary purpose of these tests was to verify the CS-PSTM. Additionally, we used them to observe CS-PSTM performance by measuring the application execution times. The last column in Tab. I contains the execution times averaged over 10 measurements. The performance is as expected. CS-PSTM behaves as a typical concurrent data structure. Generally, as the number of child processes within an application increases, the application execution time (or its makespan) decreases, i.e. the execution speed up increases.

For example, the execution time for the application OPOC in the parallel mode is less than in the sequential mode. Similarly, the execution time for the applications NP and NPP decrease as the value of the parameter *nP* increases. There is a single exception to this trend, which was observed for the application NC and for *nP* = 3 (the execution time for *nP* = 3 is greater than the execution time for *nP* = 2), which may be explained by imperfectness of experimental measurements.

The execution times for the application NC are slightly greater than for the application NP, which is most probably caused by exception handling within the function *pop*. Similarly, the execution times for the application NPNC shows that execution time is smaller (i.e. execution speed is greater) when there are more consumers and a single producer than when there are more producers and a single consumer, which implies that the sequential overhead for the function *pop* is greater than for the function *push*.

After highlighting the above mentioned general trends, we explain execution time results more specifically. We start with results for the applications NP, NC, and NPP. As can be seen from Table I, as the number of child processes (i.e. the parameter *nP*) increases from 2 to 3, and to 4:

- The execution time for the application NP expectedly decreases from 0.176s to 0.1686s, and to 0.1671s.
- The execution time for the application NC (as already explained above) unexpectedly increases from 0.2152s to 0.2189s and then expectedly decreases to 0.2137s.
- The execution time for the application NPP expectedly decreases from 0.3066s to 0.2827s, and to 0.2583s.

Next we explain the results for the application NPNC. We analyze the following three cases:

- Case 1: *nP* fixed to 1 and *nC* increases from 2 to 3. The execution time expectedly decreases from 0.2722s to 0.2695s.
- Case 2: *nC* fixed to 1 and *nP* increases from 2 to 3. The execution time somewhat unexpectedly increases from 0.2907s to 0.2934s, which may be because the total load balancing among cores becomes worst when more faster producers are combined with one slower consumer, or because of imperfectness of experimental measurements.
- Case 3: *nP* = 2 and *nC* = 2. The execution time for this case is not exactly, but somewhere in between, the cases 1 and 2. This result is as expected, because NPNC workloads with more producers (case 2) are heavier than the NPNC workloads with more consumers (case 1), and the case 3 has equal number of producers and consumers, so its NPNC workload is somewhere in between.

At this point it seems appropriate to comment the speed-up of the proposed solution. The application workload execution time decreases as the number of child processes (and thus the number of used cores) increases, but this decrease is really rather small. As can be seen from Table I, the execution time on 2, 3, and 4 cores is almost identical, so it seems that there is no performance gain when using more than 2 cores. The reason for this is that child processes just use the concurrent stack to push and pull items to/from the stack, but they do not perform any processing of data carried by the items, thus there is not enough work for child processes to share. Clearly, the performance gain would become significant, and expectedly proportional to the number of cores, if the child processes would perform more heavy data processing. We might prove this expectation by conducting appropriate experiments in our future work.

V. Conclusion

In this paper, we developed the concurrent stack on Python STM (CS-PSTM), and verified it using unit and system testing. For unit testing we developed nine test cases, whereas for system testing we developed the five application workloads (briefly referred to as OPOC, NP, NC, NPNC, and NPP). The CS-PSTM successfully passed all of the unit and the system tests.

We used the system tests also to estimate the CS-PSTM performance by measuring their execution times. The experimental results indicate that CS-PSTM provides better performance when used by more concurrent processes. Another advantage of CS-PSTM is that it may be easily adapted to be used in distributed settings.

For our future work, we plan to develop a Distributed PSTM (DPSTM) and to adapt CS-PSTM accordingly. We also plan to research on other concurrent data structures in this context.

Implementation and evaluation of video conferencing system on public cloud

Vladimir M. Ciric, Oliver M. Vojinovic, Ivan Z. Milentijevic

Abstract— **With constant growth of capacity and bandwidth of computer networks, resource demanding network applications that emerged as concepts a long time ago got their chance to gain a worldwide popularity and widespread usage. It is not the question anymore whether we can implement such applications, but rather how easy they are to implement, and how much their usage costs. In cloud-centric world of today this becomes the matter of the amount of required resources. The aim of this paper is to present the resource requirements of a video conferencing system based on open source BigBlueButton platform, while it is implemented on the Amazon AWS public cloud. The system will be implemented as the part of blended learning system. In order to determine the system limits and to give recommendations for implementation of similar systems, the results of the stress test will be given.**

Index Terms—**Video conferencing, blended learning, cloud applications.**

I. Introduction

The roots of video telephone technology can be traced back to the late 1920s and can be found with the AT&T company Bell Labs and John Logie Baird, who experimented with video phones in 1927 [1]. Videotelephony was developed in parallel with voice telephone systems from the mid-to-late 20th century. A lot of effort was put in the field by Bell Labs during the 1950s and 1960s, which lead to AT&T's Picturephone. However, the market didn't respond well, and the service was withdrawn [2].

A lot of researches and companies continued development throughout the 1980s and 1990s, which led to a number of videoconferencing systems. The systems evolved from proprietary equipment to standard technologies that were available to the general public at reasonable cost. Early attempts have failed mainly due to the cost and the quality of both equipment and resources [2]. However, videotelephony become a practical technology for regular use with the introduction of powerful video codecs in the late 20th century, combined with high-speed Internet service [3].

The constant bandwidth growth resulted with a shift from transmission of a few low-quality images per second to high-definition real-time video conferencing [4]. The price of the video conference systems got significantly lower, resulting with an adoption of such systems in different applications. One of such applications is in education, namely blended learning [5]. In a nutshell, blended learning requires the presence of both a teacher and a student, where the student has control to a certain extent over time, place, and path [6].

In recent years blended learning is gaining a lot of attention due to the growing demand for distance learning and life-long leaning [6]. The popularity emerges from the fact that it combines online digital media with traditional classroom methods, elevating the learning experience. Blended learning, armed with video conferencing, exerts good sides of both traditional and distance learning. Video conferencing becomes a common classroom activity in the online learning stage of blended learning [7].

There are a lot of educational institutions that own blended learning platforms, and even more that don't. The era of cloud computing offers a possibility to institutions which don't own such platforms to utilize public cloud resources for courses delivery. Cloud providers offers different sets of resources in the form of virtual machines, called instances, starting with low price instances with modest resources at the cost of about $0.02 per hour, up to very powerful instances which can cost more than $10 per hour [8]. Observed on a monthly basis, the price may vary from $15-$20 per month, to a few hundreds, or even thousands of dollars. Speaking about the cost difference of up to 500 times, the choice of an appropriate instance for the particular application becomes an important question.

The aim of this paper is to present the resource requirements of a video conferencing system, regarding the number of users, based on open source BigBlueButton platform, while it is implemented on the Amazon AWS public cloud. The system will be implemented as the part of blended learning system. In order to determine the system limits and give recommendations for implementation of similar systems, the results of the stress test will be given. The measured parameters will include CPU, memory and network throughput. The system will be tested on three different AWS instance types, simulating up to 400 users. Recommended user number limits will be given for each of the tested instance types.

This paper is organized as follows. Section 2 presents the proposed implementation of blended learning system, based on video conferencing platform. Section 3 is devoted to the evaluation of the system. The concluding remarks are given in Section 4.

II. Blended learning support system implementation on public AWS cloud

In order to enable students to choose their learning path and create an environment where they can schedule the

learning time on their own, blended learning support systems usually include several components [5,7]. These components should make learning material available online, should provide quizzes and tests, and not mandatory, but preferably enable two-way communication between teacher and students [5]. There are different approaches in the implementation of two-way teacher-students communication. E-mails are the oldest and the simplest solution. Nowadays, the most common asynchronous communication tools are discussion forums. Simple, but effective synchronous tool that can be found in such systems is chat. The most powerful two-way communication tool that is gaining more and more popularity is video conference [7]. Fig. 1 shows the common blended learning system components and their relation to teacher and students.

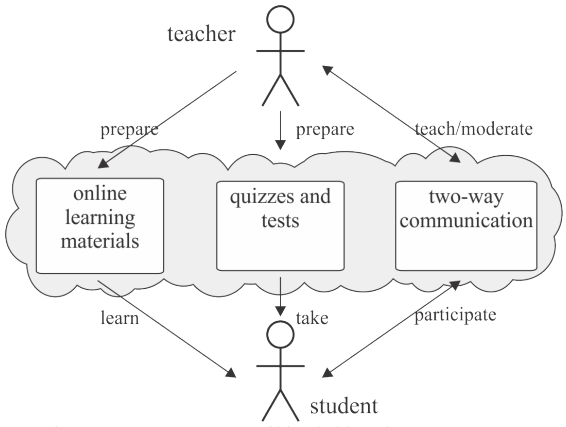

Fig. 1. The common components of blended learning systems

In order to support blended learning paradigm, the video conferencing system, if included, should provide multipoint conference, as well as video recording and streaming, with aim to enable students to schedule their learning time on their own. To provide the components from Fig. 1 two different platforms are required: distance learning platform, and video conferencing platform. Modern distance learning platforms always support both online learning materials delivery and testing of the students.

Both distance learning and video conferencing platforms are common in lecture delivery today, and there are a lot of available options for choosing the systems [9]. Seeking for a low-cost open-source and general solution, we chose the Moodle[1] as the primary learning management system, while for video conferencing we chose BigBlueButton[2] (BBB). The Moodle is chosen as the primary platform due to its ability to integrate BBB through its plug-in system, giving the students impression of accessing one platform only.

The BBB has the following features:

- it does not require any special software on the client side other than standard web-browser;
- good support and integration with Moodle;
- ability of sessions recording and streaming;
- up to 3 simultaneous videos, and 1 audio stream.

Video and audio streams that BBB can simultaneously have are: 1 video and 1 audio stream for the instructor's camera and microphone, 1 video stream for the presentation (PowerPoint, PDF, etc.), and 1 video stream for desktop share. Video stream for the presentation can be additionally used as a whiteboard. In addition, desktop sharing feature of BBB is available to create a live-stream of chosen desktop region to students.

Both Moodle and BBB systems are suitable for either private or public cloud implementation. The Amazon AWS provides a template that contains the software configuration (operating system, application server, and applications), called AMI, required to easily launch the instance with Moodle or BigBlueButton [10]. The chosen building blocks and their relations are shown in Fig. 2.

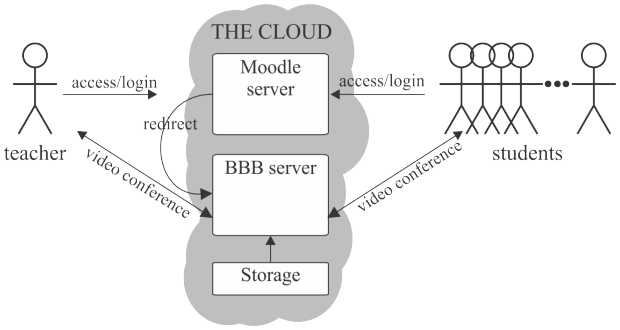

Fig. 2. The blended learning system building blocks

The Moodle can provide both online learning materials distribution, and testing the students' knowledge. Furthermore, it has tools for two-way communication with the students such as forums and chats. The BBB is an open-source project which can be easily included as a video conferencing extension of the Moodle, using available plugins for Moodle. Students are logged in using Moodle, and then, transparently, without additional login redirected to BBB video conferencing (Fig. 2). In order to store the video conference recordings additional storage is required (Fig. 2).

Fig. 3 shows the example of Moodle page prepared by the teacher. The figure shows sections in Moodle page, each devoted to one topic. In our implementation a section contains: learning objectives and learning materials, virtual classroom (given as a link to BBB Moodle plugin), additional learning materials, and online test.

Fig. 4 presents a screenshot of a web browser during a lecture in the virtual BBB classroom, which can be seen by following BBB links (the "b" icons on the Moodle page from Fig. 3). The left column of the screen contains the list of participants and the instructor video camera stream. The central part is devoted to the drawing canvas, while the right part of the screen contains the screen share showing the network simulator.

III. THE RESULTS OF THE SYSTEM STRESS TEST

The system from Fig. 2 is implemented on Amazon AWS cloud. The resources for learning materials distribution are not critical, thus the Moodle is implemented using *t2.small* instance (1 vCPU, 2 GB RAM). In order to observe the system scaling capabilities and determine limits for different instance types regarding the number of users, we tested video conferencing part of the system using three different instances: *t2.small*, *t2.medium* (2 vCPUs, 4 GB RAM), and *t2.large* (2 vCPUs, 8 GB RAM). Linux CentOS 7 is installed with Moodle v3.2 and Ubuntu 16.04 with BigBlueButton v1.1. Each instance was created with 25 GB of EBS disk reserved for operating system and applications. AWS S3 is used as associated storage (Fig. 2).

In order to perform the stress test, we connected the teacher with one audio stream, one video stream sharing teacher's camera in low resolution (320x240px), and one video stream for the presentation. We used 80 physical PCs to simulate students' connections. Students were viewers only. The connection rate was one new connection per 10 - 20 seconds. We created 5 - 10 connections per PC. During the test we observed the system behavior and user experience, and we measured objective system parameters of BBB server.

For each tested instance we recorded three events: the first time when the system unexpectedly disconnected some of already connected users due to the system load (event "D"); the time needed for establishing a new connection is significantly slowed down (event "S"); the system limit (event "L"). It is interesting to notice that when the limit is reached the system doesn't fail. It rather disconnects some (or more) of already connected users in order to connect the new ones. Moreover, connected users don't experience quality degradation. Table 1 gives the number of users for which events "D", "S", and "L" were recorded.

TABLE I
THE OCCURRENCES OF SIGNIFICANT EVENTS FOR DIFFERENT INSTANCE TYPES DURING THE SYSTEM STRESS TEST

Event \ Inst.type	*t2.small*	*t2.medium*	*t2.large*
"D"	80	200	290
"S"	140	300	300
"L"	415	371	400

The parameters measured during the stress test are given in Fig. 5. We were measuring the following: CPU utilization (Fig. 5a – Fig 5c); memory consumption (Fig. 5d – Fig. 5h); and network throughput (Fig. 5i). The parameters were measured using Linux commands *free*, *uptime*, and *vmstat*.

Figs. 5a – 5c show CPU utilization. Regarding the CPU, we were measuring the time that CPU spends in idle (Fig. 5a), the number of interrupts per second (Fig. 5b), and the number of context switches per second (Fig. 5c). All three parameters give a good insight how the CPU performs with the increase of the number of users. The official BBB documentation recommends the CPU load below 80% for system stability. This is aligned with our findings: the event "D" for *t2.small* instance appeared with 80 users (53% of time CPU spent on idle, Fig 5b), and the event "S" started with 140 users (24% of CPU idle time). We were able to connect more than 400 users (Table 1), but we don't recommend this instance type for more than 120 - 140 users due to the frequent connection losses. This can be noticed in inability for the CPU to increase the number of interrupts and context switches (Figs. 5b and 5c). This instance type was stable for up to 70 - 80 users, when the first disconnections appeared ("D", Table 1). The instance *t2.medium* with its 2 vCPUs performed much better, as expected (Table 1 and Figs. 5a – 5c).

Figs. 5d – 5h show the memory parameters. From Fig. 5e it can be seen that used memory is the same regardless the instance type, which is expected (between 1.1 and 1.6 GB). Instances *t2.*medium and *t2.large* have more available memory (Fig. 5d), which they can spend for kernel disk caches and buffers (Fig. 5h), but this didn't influence the user experiences significantly in our test. Thus, we can conclude that the memory is not a limiting factor.

Due to the completeness of the results, let us briefly mention the storage requirements, disregarding the fact that it is not a limiting factor. For hard disk capacity we chose 25GB for the Linux operating system. The requirements of the storage from Fig. 2 are as follows. The instructor's audio stream with the presentation or drawing canvas requires 110 MB per recorded hour (Mbph) for RAW recorded materials, or 10 MBph for post-processed materials. If the instructor's video camera is added, 130 MBph are required for unprocessed and 50 MBph are required for post-processed materials. When all three streams are used simultaneously, they require 240 MBph and 75 MBph for RAW and post-processed materials, respectively.

In the end, we can conclude that for system stability

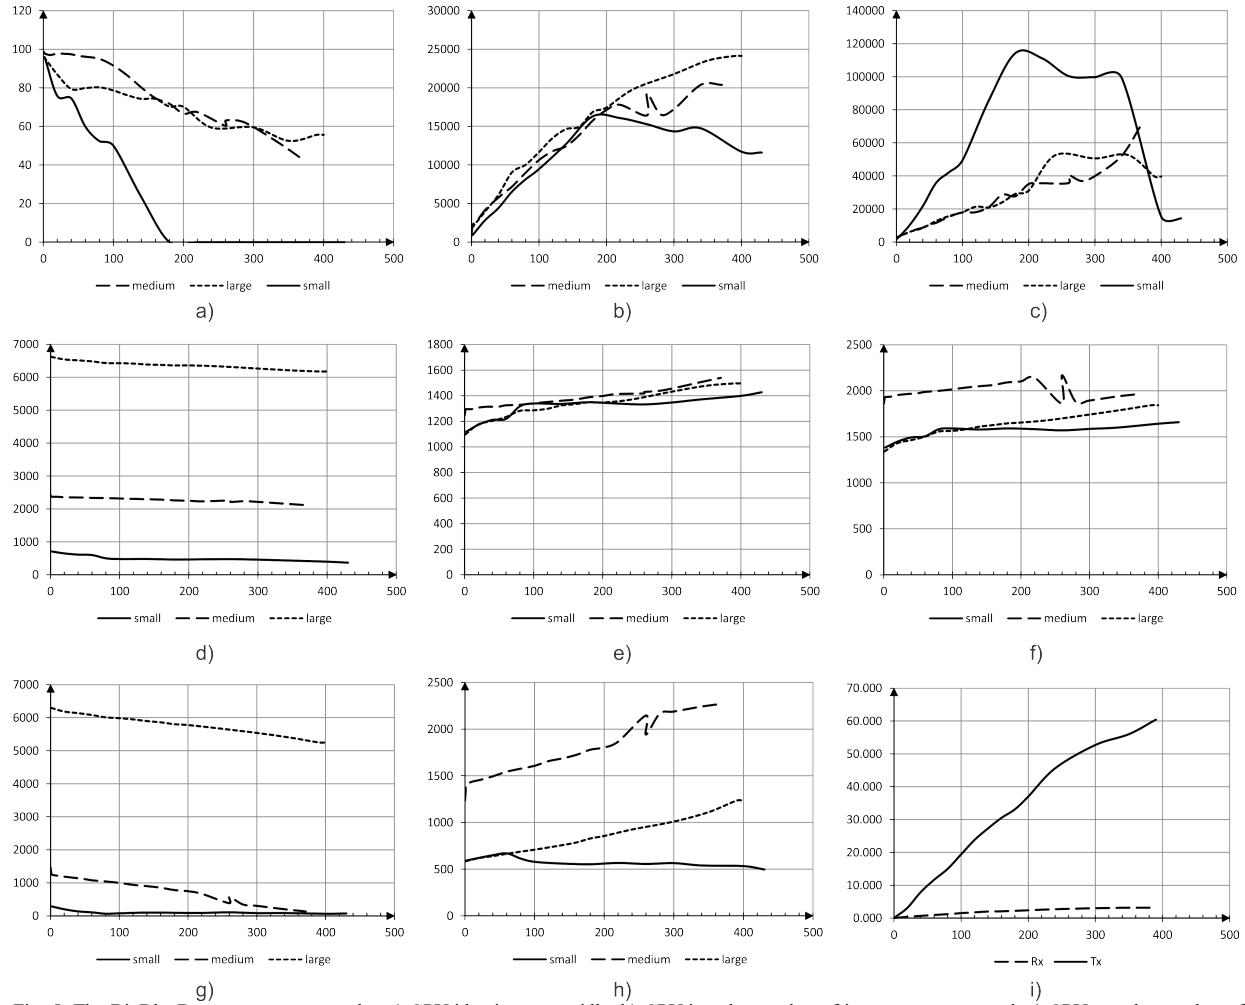

Fig. 5. The BigBlueButton stress test results: a) CPU.id - time spent idle, b) CPU.in - the number of interrupts per second, c) CPU.cs - the number of context switches per second, d) memory - available, e) memory - used, f) memory – active, g) memory – free, h) memory – kernel buffers and caches, i) network throughput

t2.small instance should be used for up to 70 users, while *t2.medium* is sufficient for up to 150 - 200 users. There was no significant gain with *t2.large* instance type.

IV. Conclusion

In this paper the resource requirements of a video conferencing system, based on open source BigBlueButton platform and implemented on the Amazon AWS public cloud, are presented. The system was implemented as the central part of blended learning system. In order to determine the system limits and give the recommendations for implementation of similar systems, the results of the stress test are given. The given parameters include CPU, memory and network throughput. The system was tested on three different AWS instance types, simulating up to 400 simultaneous users. For tested instances the recommended number of users were given.

Agile Method and ROS in Automotive Software development processes, practice, and teaching

Momčilo Krunić, Vlado Krunić, Milan Stankić, and Miroslav Popović, *Member, IEEE*

***Abstract* — Software development in Automotive industry experiencing exponential ascent of complexity these days. This is a direct implication of leading trends such as ADAS (Advanced Driver Assistance Systems) and Autonomous vehicles. In order to achieve these goals, new technologies have been introduced in Automotive software industry that have not been traditionally present, such as: Machine learning, data mining, computer vision, object fusion, … This paper describes new approach that has been introduced in Automotive software development processes and practice, such as Agile methodology and Robot Operating System (ROS), which aim is to enable seamless integration of new technologies into the vehicles, since traditional approach didn't provide optimal results. Focus of the paper is implementation of such processes and practices in the course: "Automotive Software Development Processes", at the Faculty of Technical Sciences (FTN), Novi Sad. The main idea behind this was to teach students about processes and practices, by conducting them through lectures and exercises. It has been used Autoware for this purpose. open-source platform for self-driving vehicles, based on ROS, C++ language for implementation, and LeSS (Large-Scale Scrum) framework for agile development. Implemented solutions was developed using TDD (Test Driven Development) methodology and Google test framework (gtest).**

***Index Terms*—Agile Method; ROS; Automotive Software; Processes; TDD; ADAS; Autonomous vehicles; AUTOSAR Adaptive.**

I. Introduction

THE complexity of software development in the automotive industry has grown exponentially recently, guided with new trends such as: HAD (Highly Automated Driving), ADAS (Advanced Driver Assistance Systems), and Car2X. Today, 90% of all innovations in automotive industry are coming from the E/E systems and software [1] being deployed in over hundred ECUs (Electronic Control Units). In order to meet the challenges posed by the market, leading OEMs (Original Equipment Manufacturer) and their immediate suppliers have had to adapt traditional approach to automotive software development processes like V-Model [2], to the most up-to-date trends such as scaled agile frameworks and their most influential implementations: [3] and SAFe [4], while retaining good practices that for years have provided a high level of quality of the finial software product through the implementation of the ASPICE standard [5]. The most disadvantage of the traditional approach using the V-Model, through processes defined by ASPICE, is long period between customers feedbacks. This is the main reason, among others, to introduce Agile method [6] into the world of automotive software development. Fast feedback during software development was also a main driver to include Robot Operating System - ROS [7] as a platform for rapid prototyping in order to reveal design flaws in in early phase of the project. This is crucial for cost optimization.

Very important aspect, but also a challenge, is the implementation of the standard for the functional safety ISO26262 [8] in software developed by agile processes, so that the final product can eventually end up on the public roads. Agile method does not impose strict processes during software development, which might be in contradiction with safety standard ISO26262. The practice has shown that paradigm described in "Clean Code" [9] is in compliance with ISO26262, so it is a strong recommendation to apply theses common sense set of rules during software development in order to achieve reliable and easy to maintain final software product.

One of the main topics covered in this paper is also Agile approach in teaching [10] students about such complex multidimensional problems, such us development of self-driving cars, on the Faculty of Technical Sciences (FTN), University of Novi Sad.

In second section it will be presented general and more traditional approach in the automotive software development processes. Third section provides explanation about modern approach in software development. In fourth section it has been introduced ROS and its utilization in automotive industry. Fifth section explains how Agile method and ROS are being used in practice and teaching. Sixth section concludes the paper.

II. Traditional approach in product development

Development of modern days vehicles is conducted over parallel engineering in multiple domains, such as: Mechanical, Electric/Electronic (E/E), software, etc. It is important to emphasize that parallel development is quite challenging, because of a vast amount of interdependences. For example, one supplier is developing a software for the target hardware platform provided by another supplier, but which is not available yet. Since modern vehicle has about 30,000 parts, this requires distributed engineering between OEM, and supply chain of direct (Tier 1) and indirect suppliers (Tier 2, 3). Distributed simultaneous engineering requires well defined interfaces and seamless integration at system level. Before HAD and ADAS features [11] kicked

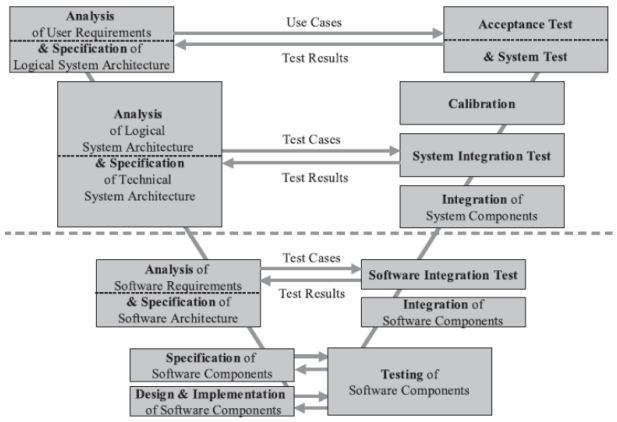

Figure 1. Automotive product development using V-Model.

in, ASPICE [5] and traditional approach has been sufficient to deliver final product with respective quality. Central part of automotive software product development is guided using V-Model [2], which is represented in Figure 1. The V-Model represents coordination of Systems engineering and Software development, where everything starts with User Requirements, which outlines the highest level of abstraction. These requirements are first break down on the System level: Logical and Technical architecture [12], and afterwards on Software level: Architecture, Design, and Implementation. Within each level of abstraction: System and Software, appropriate test cases are specified and linked, in order to verify whether requirement has been fulfilled. This represents one of the crucial points of ASPICE and V-Model, called bidirectional traceability, which is also mandatory by the Functional Safety aspects defined by the standard ISO26262 [13]. Bidirectional

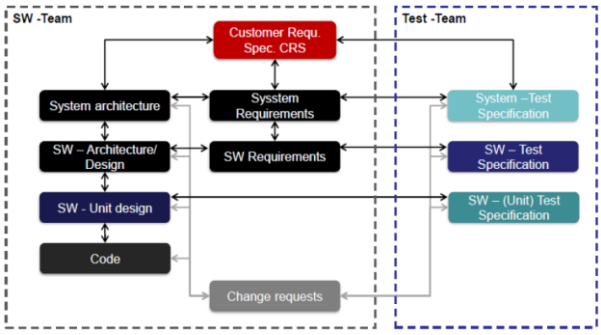

Figure 2. Concept of bidirectional traceability.

traceability enables linking on all levels of abstraction during automotive software development, from User Requirement, to implementation, testing and integration, Figure 2.

It is not hard to conclude that change request on the Customer Requirements level, triggers changes on all levels in the V-Model: System and Software, as well as on both sides: Design and Implementation (left side of V) and Testing and Integration (right side of V). This leads to a very slow process of getting customers feedback. When the changed requirement is finally fulfilled, and if the customer is not satisfied with the end result, this will implicate another change request and so on. The later in the project lifecycle change request occurs, it is harder to implement it, and it is certainly much more expensive. Today, maybe more than ever, due to the fact of exponential rise of complexity and involvement of modern trends such as: HAD, machine learning, Adaptive AUTOSAR, etc., customers' requests are changing more often, so getting a fast feedback from the customers is becoming one of the most important aspects of automotive software development, but also software development in general. Since traditional approach is not optimized for frequent change requests and getting fast feedback, this is where Agile method steps in as an alternative framework which defines certain processes and events to ensure change requests and customers feedbacks every few weeks. On the other hand, ROS [7] role is dual, but also related to fast feedback during development. In early stage of the project ROS is used as a platform for rapid prototyping whilst nor hardware or software are available yet, but algorithms need to be developed and tested. Later ROS is used for debugging and testing, because it provides powerful environment for visualization and simulation.

III. ROS AS PLATFORM FOR RAPID PROTOTYPING

Development of autonomous vehicles is in a domain of robotics. In order to improve and speed up development of such complex software systems, some of the leading OEMs (such as BMW, Daimler, Toyota, Uber, etc.) have adopted the ROS as a rapid prototyping platform, so that in the early phase of the project, while the hardware and software platform (AUTOSAR Adaptive) is not yet available, engineers will be enabled for software development and simulation. ROS was the first choice for many OEMs, because: it has a strong community (still do), it follows the similar design concepts as AUTOSAR Adaptive [14] (Service Oriented Architecture - SOA), it is portable, it is open source, and it is simple. During development, the ROS designers have been guided with following philosophical goals:

- "Hardware agnosticism"
- Peer to peer
- Tools based software design
- Multiple language support (C++/Java/Python/LISP)
- Lightweight: runs only at the edge of your modules
- Open source
- Suitable for large scale research and industry

In order to deal with complexity of robotics, the ROS design concepts are quite simple. First, it has been applied principle: "divide and conquer". All software modules have been divided into the separate processes, called nodes, which communicates over messaging interfaces. So, complexity is handled by composition of processes. There are three main parts in the ROS concept:

1. roscore: ROS Master, Parameter server, and rosout
2. Package: A virtual directory holding one or more executables (nodes)
3. Node: An agent communicating with ROS and other nodes via:
   a. Topics (publish / subscribe) using typed messages
   b. Services: Request / Response paradigm (think of method or operation) via typed messages

It is important to emphasize that ROS Master [15] is used to facilitates communication between nodes as a lookup table. Each node (publishers, subscribers, and services), when it is launched, is first registered on the ROS Master. Communication between nodes is peer-to-peer. The ROS Master is responsible for enabling that communication (Figure 3.).

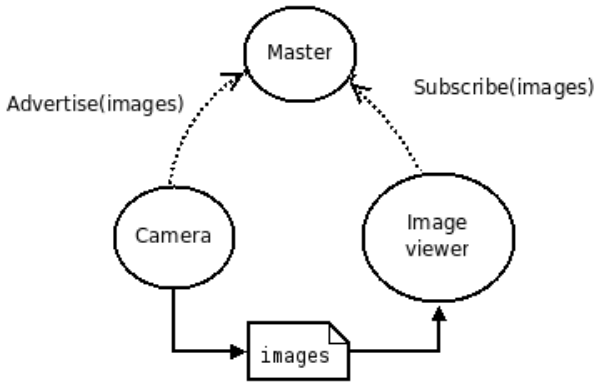

Figure 3. Messaging mechanism in inter-node communication.

For example, in Figure 3., "Camera" node is registered on the ROS Master as a publisher on a topic called "images", and "Image viewer" node is registered as a subscriber on the same topic. Each time "Camera" publishes something on the "images", "image viewer" node is being notified, and appropriate callback function is called for processing new data. This simple mechanism has been introduced to handle asynchronous communication. Synchronous communication in the ROS environment is handled by invocation of services. Beside these simple communication interfaces, ROS supports Tools based software design, by providing various set of tools for: building, running, debugging, simulation, etc. One of the most valuable features of ROS is possibility to record all messages, being sent during the session, in the so-called rosbag file. Afterwards, rosbag file can be played in the rviz [16] tool, which is named for visualization/simulation of recorded messages. In that way entire session can be reproduced and visualized which makes development and debugging much easier.

Simplicity of the entire ROS concept is the main reason of exponential adaptation on various robotics projects of today, but in automotive and teaching as well.

IV. Agile Method in Practice

Agile software development represents process framework for organizing the most modern complex projects, because it follows three simple practices: transparency, inspection, and adaptation. The main reason for publishing Agile Manifesto [17], back in 2001., was inability of traditional approach, like Waterfall [18], to handle complexity in organization of modern software development projects.

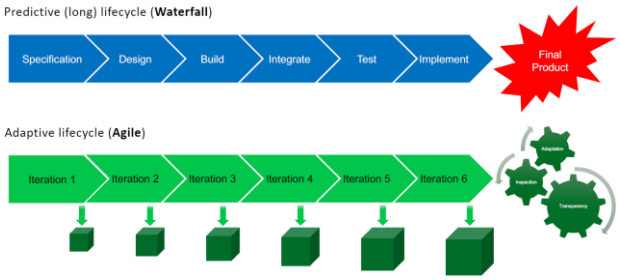

Figure 4. Product development process lifecycle – different approaches.

Figure 4. depicts main differences between two different approaches in software development processes. Traditional approach requires that product requirements, with all details specified, must be defined up front, and only then development can be initiated. This is especially hard to achieve in projects that have long lifecycle, such are in automotive industry, because during that period technology evolves and requirements are being changed. Unlike Waterfall, Agile method does not follows the strict plan, but product is being developed in short iterative cycles which enables a fast Feedback Loop: Build > Measure > Learn cycle. This way it is more likely that final product will satisfy the customers' requirements, because requirements can evolve during the product development lifecycle.

Agile manifesto, with four values and twelve principles [19], provides a philosophical vison how software product should be developed, but does not offers concrete process definitions. There are many frameworks out there that implements Agile manifesto, such as: Scrum, Kanban, Crystal, XP, etc., but the problem is that these frameworks can be applied on a small-scale project. Because of that, several frameworks have been developed for scaling Agile practices. One of the most influential frameworks for scaling Scrum is the Large-Scale Scrum (LeSS) [3], or even bigger Less Huge. Less and Less Huge gain its popularity because of simplicity. Again, as in ROS, applying simple concept on complex projects proved to be a winning ticket.

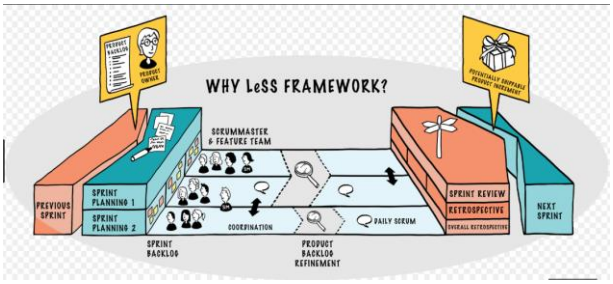

Figure 5. LeSS - framework for scaling Scrum to more than one team **[24]**.

As it can be seen in Figure 5., LeSS framework proposes just a few project roles: Customers, Product Owner (PO), Scrum Masters, and Feature Teams. It is important to emphasize that LeSS and LeSS Huge philosophy is a whole product focus. Therefore, it is important to have one PO and one product backlog.

The PO is responsible for the whole product vision and prioritization of product backlog in order to ensure efficient Return Of Investment (ROI). He/She works together with Feature teams, Scrum Masters and Customers on Product Backlog Refinement (PBR), which is an event that occurs in each Sprint (2 to 4 weeks iterative cycle) where items are broken down to a smaller tasks and owned by Feature teams, which represents cross-component and cross-functional teams that are focused on implementing and delivering a single customer feature. Afterwards, Feature teams organize Sprint planning 1 and 2, where tasks are prioritized in the teams Sprint backlogs and assigned to appropriate team

members. Each day of the Sprint teams conducting Daily Scrums, which is one of the most important events in the Sprint, because it enables transparency, one of the key principles of Agile. At the end of the Sprint, Feature teams, PO, Scrum Masters, and Customers organize an event called Sprint Review Bazaar, where teams demonstrate to the PO and Customers what has been done during the Sprint. This event is important because it enables fast feedback loop from the PO and Customers, therefor implements inspection and adaptation, another two key principles of Agile. Finally, at the end of the Sprint one of the most important event for the team occurs, called Sprint Retrospective, where each team addresses what went good and bad during the Sprint, afterwards making Action Items to improve the processes and itself. One of the key participants of LeSS and LeSS Huge is a Scrum Master. His/Hers role is to teach PO, Customers, and Feature teams to become more Agile, to practice all important aspects of Scrum, and to improve the system.

One of the pioneers in the automotive industry that applied Agile method through the LeSS and LeSS Huge frameworks is the BMW. First, they started LeSS adaptation in 2012. on the project which aim was to create the new BMW i car direct-sales process of the BMW Group. After developing for more than 2 years, Unified Sales Platform (USP) was released in time, with high customer satisfaction and high quality [20]. Because of that outcome, they decided to apply LeSS Huge, starting from 2017., on the one of the most complexed projects of today to bring autonomous driving, levels 3 and 4, on the road until 2021 [21].

In order to enable fast feedback loop and rapid prototyping BMW also decided to use ROS as a platform for simulation and development, since it has similar design concepts as AUTOSAR Adaptive, which will be used in the final product.

V. Agile Method in Teaching

In the past three years, course: "Automotive Software Development Processes (ASDP)", has been presented to students, at the Master level studies, Faculty of Technical Sciences, University of Novi Sad. In order to follow up with the latest trends in the automotive industry, and to prepare students for the future engineering work, a significant reorganization of the ASDP course has been made. First, Agile method was introduced to students by simulating the industrial processes during the teaching, so they can learn about the processes while conducting it. Second, students worked on the ROS and Autoware platform [22], which is a first open source platform for development of self-driving vehicles.

At the very beginning, Course (Product) Backlog was presented, where the professor as Course (Product) Owner (Professor), presented Stories that will be processed/completed during the next two Sprints (2 weeks), duration of lectures. At the beginning of each working day, students, together with the professor, recall what was done the previous day, then introduce what will be done on that day, and finally, if there are some confusions those are clarified. The purpose of these events was to demonstrate standard Daily Scrums. At the end of each Sprint (working week), an event called the Review bazaar was held, where students divided into the Scrum teams presents on tables what they have learned during the Sprint, similarly as Scrum teams in industry, when teams presenting what has been done during the Sprint.

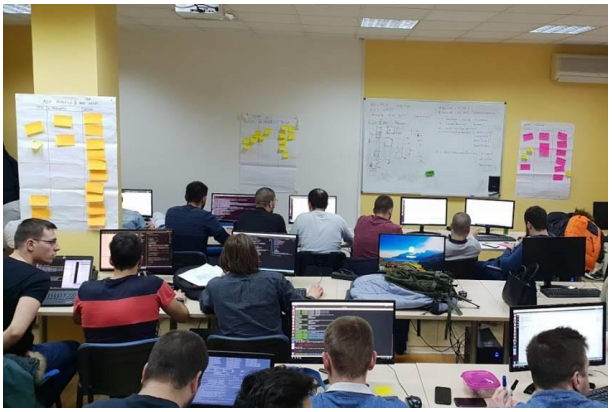

Figure 6. Scrum teams and Sprint boards.

After successfully completing the first two Sprint (lectures), the last two Sprints (Exercises) followed, where students learned about the processes that need to be followed during the development of software in the automotive industry through practical lessons. At the beginning of the Sprint, Course (Product) Backlog Refinement was carried out, where Course (Product) Owner introduced and explained the content of the new Backlog, followed by interactive discussion. Afterwards, Each Scrum team took out, from the Course (Product) Backlog, a project to work on during the Sprint. Scrum teams organized a Sprint planning event and accordingly set tasks to the team's scrum boards and started the realization (Figure 6.).

Figure 7. Scrum Teams demonstrates their projects on the Sprint Review.

Each day of the Sprint teams performed Daily Scrums and update status of tasks on the board. After successfully completing the second Sprint (Exercise), Scrum Teams demonstrated their projects at an event called Sprint Review, where each team on the projector presented their solutions to the rest of the group (Figure 7.).

Figure 8. Overall Retrospective and Action Items.

In order to conclude the Agile process, an Overall (Course) Retrospective event was held (Figure 8.) at the end of the course, where Scrum Teams displayed their impressions, bad and good, followed by a vote and defining the Action Items, whose implementation should improve the next iteration of the course. This was very important event because it provided the Feedback Loop to the Professor and Assistants.

VI. Conclusion

In this paper it has been presented modern trends in automotive industry, such as prototyping self-driving vehicles in the ROS environment, using Agile method for software development processes, as well as their impact on the approach in teaching ASDP.

During the course students were successfully realized following projects:

1. Autoware ROS node for monitoring stopping distance of vehicle based on its velocity and warn if there is a lidar detection in that area.
2. Autoware ROS node for monitoring number of lidar detections in each cell of a 2D grid around the vehicle.
3. Autoware ROS node for detecting objects in 2D grid around the vehicle based on of lidar detections.

Bearing in mind that at the beginning of the course students did not have any previous knowledge about the ROS, and the fact that all students at the end of the course successfully realized difficult projects, implicate that Agile approach in teaching was very effective.

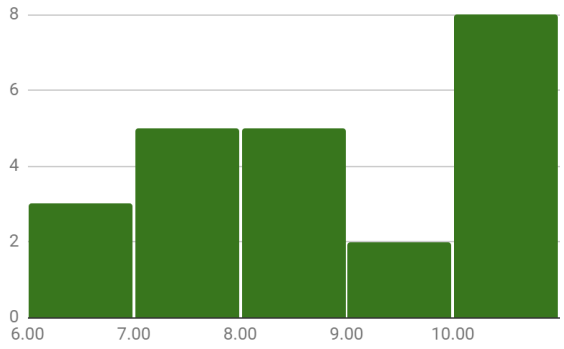

Figure 9. Distribution of grades - Theoretical part of ASDP.

At the end of the second Sprint, after the Review Bazaar, comprehensive exam took a place. It is worthwhile to notice that students did not have much time to learn at home, since an exam was during the lectures, but nevertheless distribution of grades were very positive (Figure 9.).

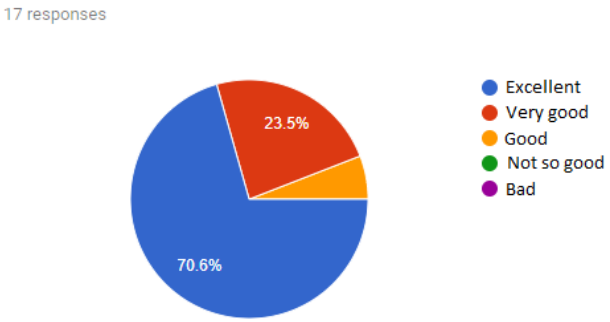

Figure 10. Anonymous survey about the overall organization of the ASDP course.

Finally, at the end of the course anonymous survey (Figure 10.) has been conducted, which showed that Agile method and new platform (ROS) induce very positive opinion among students about overall organization of the course.

Churn Prediction in Telco Industry Leveraging Call Center Data

Nenad Petrović

***Abstract*— Identifying the customers that are likely to leave and move from one service provider to another (churners) is of utmost importance in telecommunications (telco) industry due to fact that it is several times more expensive to acquire a new customer than retaining an old one. Therefore, it is mission-critical for Business Intelligence (BI) systems to identify the churning customer timely in order to support the decisioning mechanisms within the customer relationship management (CRM) software and reduce the number of lost subscribers. In this paper, it is explored how the data about customers collected by mobile operator's call center software platform can be leveraged to identify churners together with other features. As an outcome, several experiments based on classification techniques are presented. Performance of two classification approaches is compared – k-NN and neural network. Moreover, for the second approach, CPU and GPU execution time is discussed.**

***Index Terms*—CRM; data mining; deep learning; machine learning; business Intelligence.**

I. Introduction

Due to large competitiveness and high demand, customers in telecommunications (telco) industry are likely to leave and switch to another operator if they find a more suitable offer that will satisfy their current needs for lower price. This process is known as *churn*. Every year, telco companies suffer from huge losses caused by churn, as it is much more expensive (5 to 10 times) to acquire a new customer than to retain the existing one [1]. Therefore, it is of utmost importance in telco industry to recognize the customers that are likely to leave (*churners*) timely and react accordingly in order to retain them [1-4]. Once they are identified, more attractive products and services can be offered to these users in order to prevent them from changing their provider. Moreover, it was shown that even small improvement in churn identification could be highly beneficial [2].

For this reason, one of the main roles of Business Intelligence (BI) [5] in Customer Relationship Management Software used by telco operators is to identify customers that are about to leave operator and leverage that information to adapt the underlying decisioning mechanisms in order to execute the corresponding strategy that could possibly lead to reduced number of lost customers.

In this paper, it is explored how data analysis techniques based on data mining and machine learning algorithms can be leveraged to detect the potential churners. As an outcome, classification approach for churn prediction is proposed, its results presented and evaluated. Moreover, two solutions are compared – the one that is leveraging the transaction data coming from call center software together with customer characteristics (such as number of active/suspended SIMs, spending) and another one that does not involve the data coming from call center. The goal of the experiment is to examine whether the analysis of call center transaction data is beneficial for churn prediction or no. Moreover, the processing time necessary for training and prediction is discussed, considering the results achieved by execution on CPU and GPU. Finally, two classification implementations are compared: deep learning-based and k-nearest neighbours.

II. Background and related work

A. Data analysis techniques

Data analysis techniques include various data mining, machine learning, artificial intelligence and statistical algorithms that are used to extract useful patterns, relations and recognize trends from large quantity of stored data. An overview of data analysis techniques widely used in telecommunications industry customer relationship management is given in Table I [6, 7].

TABLE I
OVERVIEW OF DATA ANALYSIS TECHNIQUES

Technique	Description
Clustering	The task of grouping a set of observed objects in such way that objects within the same group are more similar to each other than to those in other groups.
Classification	Identifying to which of a set of categories, a new observation belongs to, on the basis of a training dataset containing observation whose category membership is already known.
Regression	A set of statistical processes for estimating how the typical value of the dependent variable changes when one of the independent variables varies, while others independent variables are fixed.
Association rule discovery	Association rule discovery has purpose to identify the associations and relationships between the items or events that occur within the input dataset.

When the goal of data analysis mechanism is to make predictions (as churn prediction that is main topic of this paper), the data is split into two datasets: training and test set. Training set is used to fit the parameters of the model using a supervised learning method. Moreover, a label variable is added to the dataset to denote the category where the observation belongs. After that, the constructed model is used to predict responses for new observations coming from another dataset – called test set.

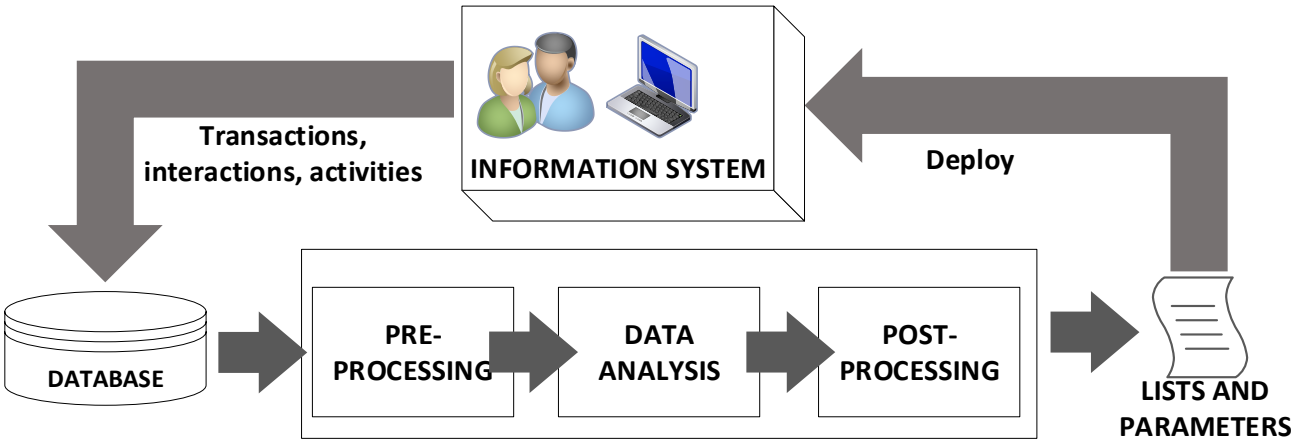

Fig. 1. Adopting BI in enterprise information systems

In [6], clustering was used to derive thresholds for business rules related to product availability, while association rule analysis was leveraged to design product bundles in telco operator's call center platform for different groups of customers. In [3] and [8], several classification algorithms were used for churn prediction based on telco customer features. Moreover, in [2], an approach for context-aware churn prediction in telco industry relying on ensemble of several algorithms was presented. In this paper, the decision is to rely on classification methods due to effectiveness of the approach, satisfactory performance and simplicity at the same time [3, 7, 8].

B. Business Intelligence (BI)

Also referred to as business analytics, it is a term used to describe a range of different applications and technologies used to extract and analyze large amounts of data to aid the process of decision making. BI includes both data analysis and querying tools [5]. Typical process of adopting BI within enterprise information systems is shown in Fig. 1.

First, the step of pre-processing is performed to transform the collected data about customer transactions, interactions and activities to a form suitable for corresponding data analysis algorithms. Queries are executed in order to filter data and select the desired attributes. Optionally, data integration can be done if it comes from heterogeneous information systems. Once the data is prepared, the algorithms for data analysis can be executed. Furthermore, the obtained results are interpreted and stored in a form that is deployable within the information systems environment, such as customer lists and budget parameters so they can be immediately used to drive the decisioning process [5].

C. Deep learning

Deep learning is a family of machine learning methods based on artificial neural networks. The learning process itself can be either supervised, semi-supervised or unsupervised. Deep learning has been applied in various areas, such as computer vision, speech recognition, natural language processing, audio recognition and bioinformatics.

Artificial neural network (ANN) is a group of nodes interconnected through weighted links. A node (also referred to as *neuron* or *perceptron*) is a computational unit containing one or more weighted input connections, a transfer function that combines the inputs, and an output connection. It receives the signal, processes it and then forwards it to other nodes connected to it.

In neural networks, three types of layers are identified: 1) input layer, that corresponds to the input variables 2) hidden layers – the nodes between input and output layers, more than one layer like this can be present within the network architecture 3) output layer – a layer of nodes that produce the output variables.

A *deep neural network* (DNN) is an artificial neural network (ANN) with multiple layers between the input and output layers [9]. A single-layer neural network can be only used to represent linearly separable functions, which is the case for very simple problems. However, most problems are not linearly separable. In [10], it was stated that two hidden layers are sufficient for creating classification regions of any desired shape.

In this paper, neural networks are used for classification approach to customer churn prediction based on supervised learning.

III. CALL CENTER CASE STUDY

Call center operators access a web application that supports the process of negotiation with customers in cases of tariff plan change, activation of discounts or additional services (such as extra GBs for mobile data traffic, unlimited SMS messages), as illustrated in Fig. 2. Whether it is possible to activate some service for the selected customer is determined by the mechanisms of decision logic. For decisioning, several factors are taken into account. First, there is a matrix of compatible products within the catalog which determines the services that go together with a given tariff plan. Moreover, the lists of customers are considered. Certain types of tariffs and services might be reserved only for specific customer categories (big enterprise, small company or churner). On the other side, the ability to activate some service is also determined by customer's budget, which is based on average monthly bill value. Budget calculation formulas contain thresholds and coefficients that are customer type-dependent. Customer lists are updated regularly to take into account the new interactions with customers, transactions, activities and bill changes. Once call center operator finds the right deal for the customer, it is added to the customer basket. Finally, if user accepts the deal offered by the operator, it is submitted for activation.

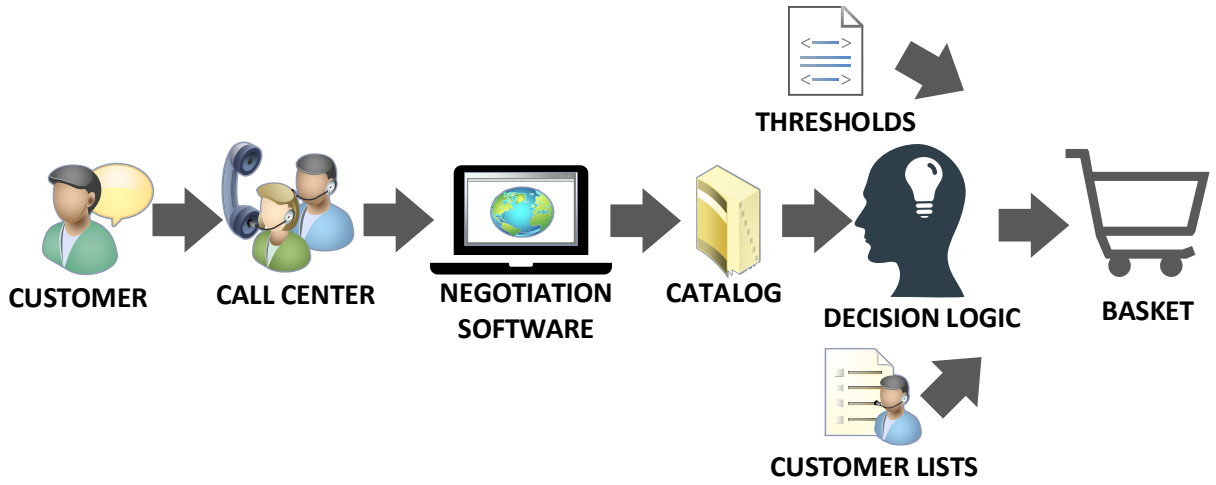

Fig. 2. Call center software platform illustration

Separating potential churners from other customers is of utmost importance for this application, as they are treated differently. The budget thresholds are often more tolerant in this case and some specific services might be offered in order to retain the customers with high churn risk The whole business process of churning customer prediction and their treatment is shown in Fig. 3, from two different perspectives – data analyst and call center operator. The task of data analyst is to construct the lists of customers that are likely to leave applying data analysis techniques that are deployed to the call center application. After that, while call center operators negotiates with customers, it is checked whether they belong to the list of churners. If it is true, another perspective in application is opened, showing special services that are not available for other users.

IV. Churn Prediction Experiments and Results

In this section, an approach of churn identification based on call center transaction data using classification algorithm is presented. Moreover, the obtained results are evaluated, discussed and compared to the case when call center transaction data is not taken into account. The data was prepared using SAS Enterprise Guide[1], while the predictions themselves were done using two open-source libraries: 1) TensorFlow[2], a GPU-supported library for Python programming language in case of deep learning-based approach. Deep learning refers to a class of machine learning algorithms relying on artificial neural networks, that consist of a cascade of multiple layers of nonlinear processing units where each successive layer uses the output

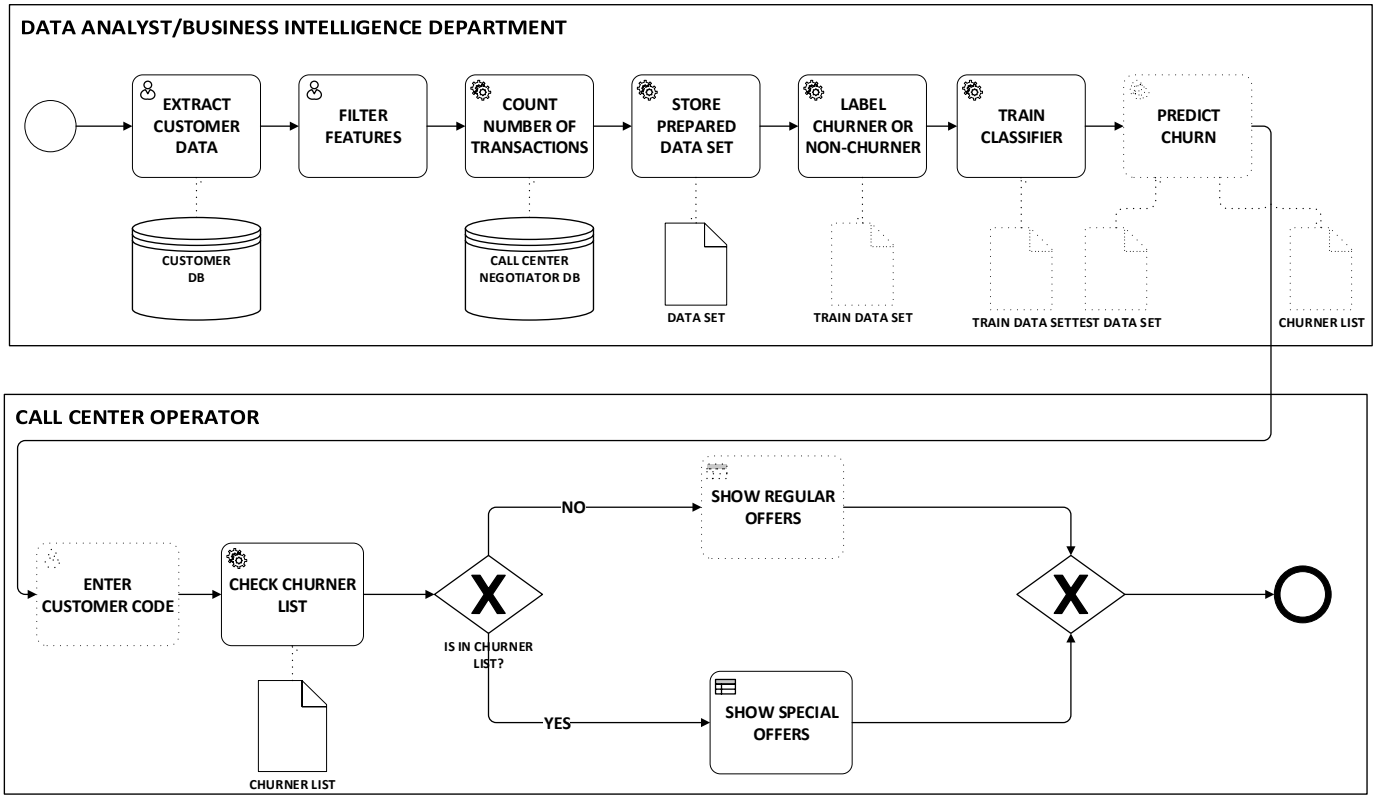

Fig. 3. Business process of churning customer prediction and their treatment in BPMN notation

[1] http://support.sas.com/software/products/enterprise-guide/index.html
[2] https://www.tensorflow.org/

from the previous layer as input. In this paper, deep learning is used for supervised learning. 2) Java-ML[3] library for Java programming language in case of k-nearest neighbours method [11]. In k-NN classification, an object is assigned to the class most common among its k nearest neighbours (k – positive integer, typically small) [12].

The performance evaluation was done on a server equipped with AMD Ryzen 7 1700X octa-core CPU running at 3.80GHz, 64GB DDR4 RAM and NVIDIA Quadro P2000 GPU with 4GB VRAM. For GPU-supported execution, a CUDA-compatible hardware is needed, which is the case with the described configuration.

In pre-processing phase, the data was prepared by executing queries against the negotiator software database. For 200 anonymized customers, the features shown in Table II were extracted for period from 1st January 2016 to 31st December 2018. Five features were taken into account: 1) number of service activations (transactions) via call center software platform 2) average spending taking into account other services provided by the operator, such as DSL and PBX 3) average spending per SIM 4) number of active SIMs 5) number of suspended SIMs. Additional column (label) with value 0 for non-churners and 1 for churners was added, considered as a dependent (outcome) variable, while other features were treated as independent In training set, this label is used for supervised learning, while in test set it is used to check whether the prediction is correct or not.

TABLE II
FEATURES FOR CLASSIFICATION-BASED CHURN PREDICTION

Number of transactions	Avg. spending	Avg. spending per SIM	Active SIMs	Suspended SIMs

After preparation, data was divided into disjoint sets – train and test set, in different ratios. In Table III, an overview of the achieved results in case of different size of training and test set is given for case when call center transactions are taken into account (third column) and not (fourth column) for TensorFlow implementation based on deep learning.

TABLE III
HOW CALL CENTER TRANSACTION DATA AFFECTS THE CHURN PREDICTION PERFORMANCE IN CASE OF DEEP LEARNING

Training set size	Test set size	Correct/Test size [%] (with call center data)	Correct/Test size [%] (w/o call center data)
50	150	90.67	82.67
75	125	91.20	84.00
100	100	94.00	88.00
150	50	96.00	92.00

According to the results, it can be noticed that churn prediction performs slightly better in case when number of call center transactions for each customer is also included. This outcome can be explained by the fact that number of executed transactions via call center platform encapsulates an important aspect of customer behavior.

Moreover, in Table IV, the results of processing time compared in case of GPU and CPU execution are given for both the training and test phases. In this case, a neural network with 2 hidden layers was used (3 nodes per layer). Due to insufficient amount of customer data available, synthetic data was generated using a custom random value generator written in Java for purposes of processing time evaluation.

TABLE IV
COMPARISON OF CPU AND GPU EXECUTION TIME

Set size	CPU train	CPU pred.	GPU train	GPU pred.
100	4.73	3.29	5.13	3.14
1000	5.13	5.05	5.26	3.89
10000	25.5	11.23	24.74	9.42
100000	101.31	22.43	50.23	12.68
500000	161.17	29.14	79.21	15.37

According to the obtained results, it can be noticed that the execution of both training and prediction is in favor of GPU, as the set size increases. However, in case of the smallest dataset (100 observations), the execution of training phase was faster on CPU, while they are comparable in case of medium-sized datasets (1000 and 10000). In case of last two largest datasets, the advantage of GPU becomes more significant and is a bit more beneficial in training phase. When it comes to the execution speed of churn prediction, a similar trend was noticed for larger datasets, while the time needed for prediction was comparable even for the smallest dataset. This can be explained by the fact that GPU calculation parallelism is better exploited by TensorFlow when it comes to deep neural network learning for larger amount of data.

Furthermore, in Table V, the performance of churn prediction for different neural network configurations (number of hidden layers and nodes per layer) is shown. It can be noticed that the number of correct predictions is similar for configurations with more than two nodes per layer. When it comes to the number of layers, it can be noticed that the performance increases up to 3, while the further increase of layer number does not seem beneficial.

TABLE V
CHURN PREDICTION IN CASE OF DIFFERENT NEURAL NETWORK CONFIGURATIONS

Number of hidden layers	Nodes per layer	Correct/Test size [%] (with call center data)
1	1	62
1	2	78
1	3	92
1	4	92
1	5	94
1	6	92
2	3	96
3	3	98
4	5	92
2	5	96
2	10	96

On the other side, in Table VI, an overview of the results obtained in case of k-NN approach is given when call center

[3] http://java-ml.sourceforge.net/

transaction data was included. It can be noticed that it gives slightly larger number of correct predictions compared to deep learning implementation in case of smaller training sets, while deep learning performs better in case of larger training sets.

TABLE VI
CHURN PREDICTION IN CASE OF K-NN ALGORITHM LEVERAGING CALL CENTER TRANSACTION DATA

Training set size	Test set size	Correct/Test size [%] (with call center data)
50	150	92.00
75	125	92.80
100	100	93.00
150	50	94.00

In Fig. 4, it is shown how the percentage of correct predictions depends on k parameter in k-nearest neighbours algorithm in case of training set that consists of 150 observations and test set of 50 observations. It can be noticed that it increases until value 4. After that, it starts decreasing, with significant drop at k=6. For this reason, it was decided to use k=4 in the experiments.

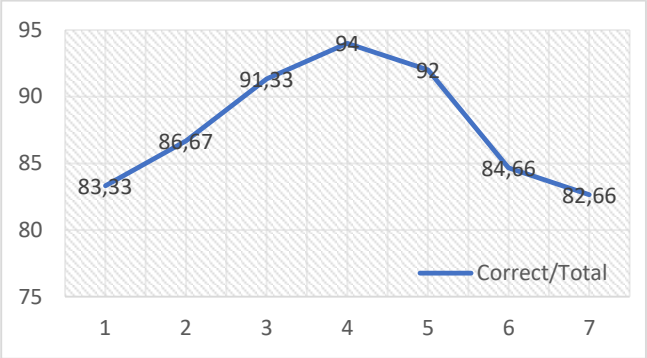

Fig. 4. Illustration how ratio of correct/total [%] predictions depends on k parameter value in k-NN algorithm

Moreover, association rule discovery algorithm was executed against the call center transaction data using SAS Enterprise Miner[4] in order to explore churning customer behavior when it comes to activation of digital mobile services, using the code similar to the one presented in [6]. However, due to relatively small number of transactions involving churn customers (except several outliers), it was not possible to discover rules with significant support and confidence that could illustrate behavior and leveraged in combination with other techniques such as clustering or classification. The value for minimum confidence was 75, while minimum support was 20. Further decrease of these thresholds did not lead to discovery of meaningful patterns.

A number of call center-aided transactions per customer for 50 churning (red) and 50 non-churning (blue) customers extracted from the dataset is illustrated in Fig. 5. The similar trend was also noticed for overall average spending and average spending per SIM, showing much lower values for churning than in case of non-churning users. Therefore, these features contribute to churn prediction due to their discriminative nature noticed in this case.

[4] https://www.sas.com/en_us/software/enterprise-miner.html

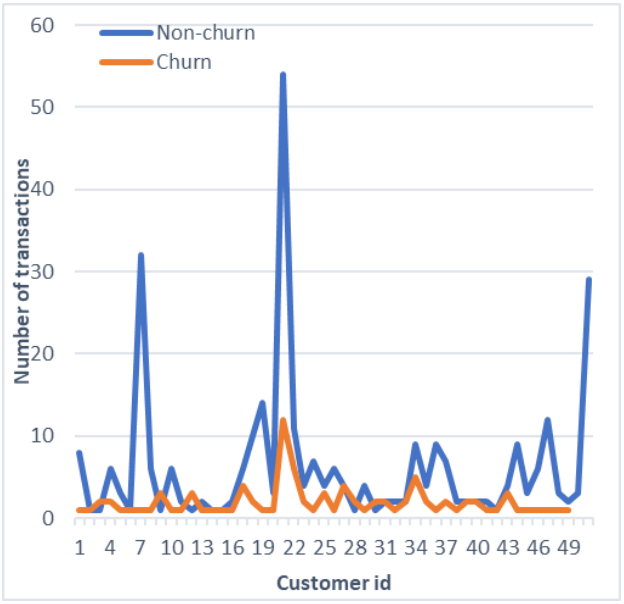

Fig. 5. Number of call center-aided transactions per customer for 50 churning (red) and 50 non-churning (blue) customers

V. CONCLUSION AND FUTURE WORK

In this paper, a method for churn prediction in telco industry leveraging the customer transaction data produced by call center software platform together with other customer features was presented. It can be concluded that addition of call center transaction-related features leads to slightly better churn prediction. However, when it comes to churn prediction, it is already known that even small improvement can save telco company from significant revenue loss. Moreover, it was shown that utilization of GPU-enabled machine learning libraries can lead to faster execution on adequate hardware in case of large customer databases, which is the case of large-scale and international telco operators. On the other side, leveraging GPU for churn prediction based on small customer bases might not be beneficial at all. Furthermore, an approach to exploit association rule discovery for churn prediction was not successful, due to insufficient number of transactions available for churning customers. Finally, it can be concluded that k-NN classification performs better in case of smaller training sets, while deep learning approach is more beneficial for larger training sets. It is planned in future to experiment with different customer features and ensemble of various data analysis techniques. Also, the performance of the developed methods will be evaluated on larger non-synthetic datasets and performance illustrated with more parameters included.

An implementation of the ARINC 653 APEX API services

Anja Veselinović, Branislav M. Todorović, Miloš Pilipović

***Abstract* — ARINC 653 is a specification used for integrating avionics system on a modern aircraft. The APEX (Application/Executive) interface, between the application software and the Core Software, defines a set of facilities which the system will provide for application software to control the scheduling, communication and status information of its internal processing elements. The interface and the behavior of the API (Application Program Interface) services are specified by ARINC 653. The ARINC 653 APEX API provides services to the applications. The aim of this paper is to present principles of ARINC 653 services implementation.**

***Keywords* — ARINC 653, APEX interface, API services, Integrated Modular Avionics, Partitioning, Partition Management, Partition Communication, Health Monitoring**

I. Introduction

Nowadays, the avionics industry is moving towards the use of a new architecture for aircraft systems called Integrated Modular Avionics (IMA). The IMA architecture consists of a distributed system, where many aircraft applications can be executed in the same hardware module, sharing computing resources, communications and input and output devices. The ARINC 653 [1] specification is one of the most important blocks from the IMA definition, where the partitioning concept emerges as a way to ensure protection and functional separation between applications, usually for fault containment and ease of verification, validation and certification. ARINC 653 is used extensively on new civil and military aircrafts produced by Airbus, Boeing and others [2].

The ARINC 653 defines a general purpose APEX interface Application Program Interface (API) between the Core Software (CSW) of an Avionics Computer Resource (ACR) and the application software. The software specifications of the APEX interface are High-Order Language (HOL) independent, allowing systems using different languages to follow this interface. ARINC 653 time and space separation architectures enable applications with different levels of safety criticality to share the common compute platform, thereby optimizing the use of computer resources and allowing the Human–Machine Interface (HMI), flight controls, and aircraft systems to safely share the common compute resource. ARINC 653 was designed for safety certification, which decreased aircraft programs' certification risk.

This paper is organized as follows. In Section II we present basic concepts of the execution environment of the system and interaction between the individual elements within the system. ARINC 653 defines Basic [1] and Extended Services [3] for the API (specified in section III). The data type names, service request names, parameter names and order of parameters are defined by this standard. ARINC 653 was developed for use in avionics systems, but it is equally suitable for any system that requires API services, and partitioning mechanisms to enable multiple hosted applications (of the same or differing safety levels) to operate on platform hardware. The Ada and C language are recommended and supported by airlines for application software development, but other languages can also be used. C language is used in example of Health Monitoring services implementation, given in section IV.

II. IMA System Architecture

The first level of decomposition of an integrated module IMA consists of two major categories:

- Partitioned application software
- Core module

A core module can contain one or more individual processors, each consisting of one or more processor cores. The core module architecture has influence on the O/S implementation, but not on the APEX interface used by the application software of each partition. Application software should be portable between core modules and between individual processor of core module without modifying its interface with the O/S.

In order to isolate multiple partitions in a shared resource environment, the hardware should provide the O/S with the ability to restrict memory spaces processing time and access to I/O for each individual partition.

III. The ARINC 653 APEX Services

The ARINC 653 APEX [4] services are API calls belonging in six categories:

This work was partially funded by the Ministry of Education, Science and Technological Development of the Republic of Serbia under Grant TR-32030.

Miloš Pilipović RT-RK Institute for Computer Based Systems, Narodnog fronta 23A, 21000 Novi Sad, Serbia (e-mail: milos.pilipovic@rt-rk.com).

A. Partition Management

Central to the ARINC 653 philosophy is the concept of partitioning. Partitions are scheduled on a fixed, cyclic basic. Partitions are activated by being assigned to one or more partition time windows within major time frame. Each partition time window is defined by its offset from the start of the major time frame and expected duration. Configuration of all partitions throughout the whole system is expected to be under the control of the system integrator and maintained with configuration tables.

1) Partition Control

The O/S starts the application partitions when the O/S enters operational state. The application is responsible for invoking the appropriate APEX calls to transition the partition from one operational mode to another.

2) Partition Scheduling

Scheduling of partitions is deterministic over time. The main characteristics of the module scheduling model are:

- From the application developer perspective the scheduling unit is a partition
- Partitions have no priority
- The module scheduling algorithm is predetermined, repetitive with a fixed periodicity (major time frame).

3) Partition Operating Modes

Operating mode represents the current execution state of the partition. Partition operating modes (shown in Figure 1) are:

- IDLE – In this mode the partition is not eligible for application execution.
- NORMAL – The partition's initialization is complete and process scheduler is active.
- COLD_START – In this mode the partition's initialization phase is in progress.
- WARM_START – Application is executing its respective initialization code. This mode is similar to the COLD_START, but the hardware context in which the partition starts may be different.

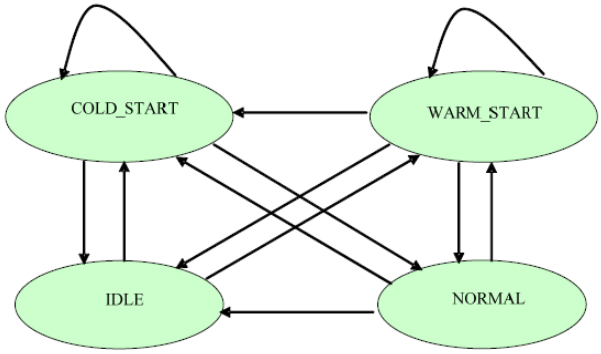

Fig. 1: Partition Operating Modes

B. Process Management

A process is a programming unit contained within a partition which executes concurrently with other processes of the same partition. Process may be designed for periodic or aperiodic execution. The processes are not directly visible outside of the partition. The partition should be responsible for the behavior of its defined processes.

C. Time Management

Time management is an important characteristic of an O/S used in real-time systems. The O/S provides time slicing for module scheduling, deadline, periodicity and delays for process scheduling and time-outs for intrapartition and interpartition communication.

As long as a process performs its entire processing without using its whole time capacity, the deadline is met. If a process requires more processing than the time capacity, the deadline is missed. When the deadline is missed, a health monitoring error will be raised (described in sections III and IV).

D. Memory Management

Partitions and their associated memory spaces are defined during system configuration and initialization. There are no memory allocation services in the APEX interface.

E. Interpartition Communication

A major part of ARINC 653 standard is the definition of the communication between APEX partitions, presented in Figure 2. All interpartition communication is conducted via messages. A message is defined as a contiguous block of data of finite length. A message is sent from a single source to one or more destinations. From the application viewpoint, a message is a collection of data which is sent or received to/from a specific port.

A channel is basic mechanism for linking partitions by messages. It defines a logical link between one source and one or more destinations. Partitions have access to channels in defined access points called ports. A port provides the required resources that allow a specific partition to send or receive messages in a specific channel.

At the application level, messages are atomic entries (either the whole message is received or nothing). The core module is responsible for encapsulating and transporting messages.

Messages may be communicated across different communication levels:

- Within core modules – allows messages to be passed between partitions supported by the same core module
- Between the core modules – allows messages to be passed between multiple core modules via a communication bus
- Between core modules and a non-ARINC 653 component – allows messages to be passed between core modules and devices that do not host an ARINC 653 O/S (traditional LRUs, sensors, etc.) via various communication buses.

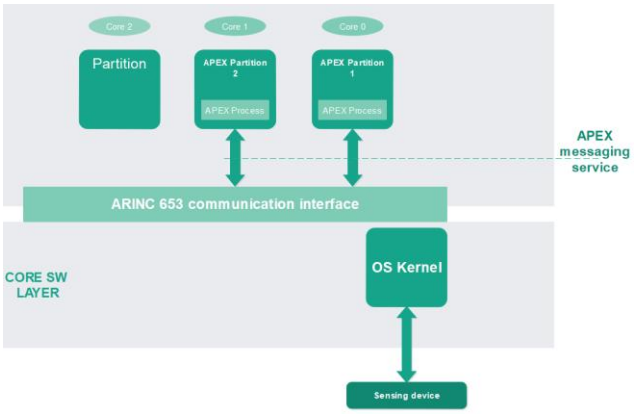

Figure 2: APEX Interpartition Communication

Communications between partitions, or between partitions and external entities, use the same services and are independent of the underlying transport mechanism. The core module is responsible for encapsulating and transporting messages.

F. Intrapartition Communication

Three communication mechanisms are available for intrapartition communication. The first mechanism allows inter-process communication and synchronization via partition-defined buffers and blackboards. The second allows inter-process synchronization via partition-defined counting semaphores and events. The third allows inter-process mutual exclusion via partition-defined mutexes.

1) Buffer Services

A buffer is a communication object used by processes of a same partition to send or receive messages. The maximum number of messages supported and maximum message size is defined at buffer creation.
A buffer is created during the partition initialization phase.

2) Blackboard Services

A blackboard is a communication object used by processes of a same partition to send or receive messages. A blackboard does not use message queues. Each new occurrence of a message overwrites any other.

3) Semaphore Services

A counting semaphore is a synchronization object used to provide access to partition resources.

4) Event Services

An event is a synchronization object used to notify the occurrence of a condition to processes that may be waiting for condition to occur. An event must be created during the partition's initialization phase before it can be used.

5) Mutex Services

A mutex is a synchronization object commonly used to control access to partition resources. Only one process at a time can own a specific mutex.

6) Health Monitor

In general, Health Monitor (HM) functions are responsible for responding to and reporting hardware, application and O/S software errors and failures [5]. ARINC 653 supports HM by providing HM configuration tables and an application level error handler process. Figure 3 illustrates the ARINC 653 HM decision logic. HM services are described in section IV.

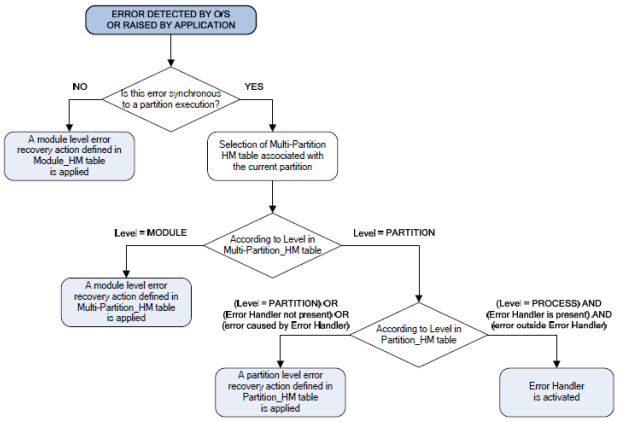

Figure 3: HM Decision Logic

IV. HEALTH MONITORING SERVICES IMPLEMENTATION

The HM is invoked by an application calling the RAISE_APPLICATION_ERROR service or by the O/S or hardware detecting an error. The recovery action is dependent on the error level. The recovery actions for process level errors are defined by the application programmer in a special error handler process.

A. REPORT_APPLICATION_MESSAGE

This service request allows the current partition to transmit a message to the HM function. Code implementation is presented in Figure 3.

```
extern void REPORT_APPLICATION_MESSAGE (
/*in */ MESSAGE_ADDR_TYPE MESSAGE_ADDR,
/*in */ MESSAGE_SIZE_TYPE LENGTH,
/*out*/ RETURN_CODE_TYPE *RETURN_CODE );
```

Figure 3: REPORT_APPLICATION_MESSAGE

B. CREATE_ERROR_HANDLER

This service request creates an error handler process for the current partition. The process has no identifier (ID) and cannot be accessed by the other processes of the partition. It is a special aperiodic process with the highest priority, no deadline, and entry point defined by this service is invoked by the O/S when a detected error is evaluated as a process level error. Figure 4 presents code implementation of this service.

The error handler is written by application programmer. It can stop and restart the failed process with the STOP and START services, restart (COLD_START or WARM_START) or shutdown the partition by the SET_PARTITION_MODE (IDLE) service. The error handler cannot be interrupted or blocked.

```
extern void CREATE_ERROR_HANDLER (
/*in */ SYSTEM_ADDRESS_TYPE ENTRY_POINT,
/*in */ STACK_SIZE_TYPE STACK_SIZE,
/*out*/ RETURN_CODE_TYPE *RETURN_CODE );
```

Figure 4: CREATE_ERROR_HANDLER

C. GET_ERROR_STATUS

This service must be used by the error handler process to determine the error code, the identifier of the faulty process, the address at which the error occurs, and the message associated with the fault. If more than one process is in error, the service may be called in a loop in the error handler until there are no more processes reported as being in error (Code implementation is shown in Figure 5).

```
extern void GET_ERROR_STATUS (
/*out*/ ERROR_STATUS_TYPE *ERROR_STATUS,
/*out*/ RETURN_CODE_TYPE *RETURN_CODE );
```

Figure 5: GET_ERROR_STATUS

D. RAISE_APPLICATION_ERROR

The RAISE_APPLICATION_ERROR (shown in Figure 6) service request allows a running process to invoke the error handler process for the specific error code APPLICATION_ERROR. The error handler process can read the message passed using the GET_ERROR_STATUS. The error handler of the partition is then started (if created) to take the recovery action for the process which raises the error code.

The ERROR_CODE parameter has been retained for backwards compatibility. It can only be set to APPLICATION_ERROR.

```
extern void RAISE_APPLICATION_ERROR (
/*in */ ERROR_CODE_TYPE ERROR_CODE,
/*in */ MESSAGE_ADDR_TYPE MESSAGE_ADDR,
/*in */ ERROR_MESSAGE_SIZE_TYPE LENGTH,
/*out*/ RETURN_CODE_TYPE *RETURN_CODE );
```

Figure 6: RAISE_APPLICATION_ERROR

E. CONFIGURE_ERROR_HANDLER

This (implementation presented in Figure 7) service request allows the current partition to configure the behavior of how process scheduling of other processor cores will be managed for the partition when the error handler process is executing. This service configures whether processes on the other processor cores run concurrently or do not run concurrently (i.e., pause) while the error handler process is running.

```
extern void CONFIGURE_ERROR_HANDLER (
/*in */ ERROR_HANDLER_CONCURRENCY_CONTROL_TYPE CONCURRENCY_CONTROL,
/*in */ PROCESSOR_CORE_ID_TYPE PROCESSOR_CORE_ID,
/*out*/ RETURN_CODE_TYPE *RETURN_CODE );
```

Figure 7: CONFIGURE_ERROR_HANDLER

Health monitoring error code, status and control types are presented in Figure 8.

```
typedef
enum {
DEADLINE_MISSED = 0,
APPLICATION_ERROR = 1,
NUMERIC_ERROR = 2,
ILLEGAL_REQUEST = 3,
STACK_OVERFLOW = 4,
MEMORY_VIOLATION = 5,
HARDWARE_FAULT = 6,
POWER_FAIL = 7
} ERROR_CODE_TYPE;

typedef
struct {
ERROR_CODE_TYPE ERROR_CODE;
ERROR_MESSAGE_SIZE_TYPE LENGTH;
PROCESS_ID_TYPE FAILED_PROCESS_ID;
SYSTEM_ADDRESS_TYPE FAILED_ADDRESS;
ERROR_MESSAGE_TYPE MESSAGE;
} ERROR_STATUS_TYPE;

typedef
enum {
PROCESSES_PAUSE = 0,
PROCESSES_SCHEDULED = 1
} ERROR_HANDLER_CONCURRENCY_CONTROL_TYPE;
```

Figure 8: HM types

V. CONCLUSION

The following objectives are achieved with the ARINC 653 APEX interface:

1. Portability: The ARINC 653 APEX interface facilitates portability of the software. ARINC 653 APEX interface specification is language and hardware independent.
2. Reusability: The ARINC 653 APEX interface allows the production of reusable application code for IMA systems. This interface will reduce the amount of customizing required when a component is reused.
3. Modularity: The ARINC 653 APEX interface provides the benefits of modularity when developing application software.
4. Integration of Software of Multiple Criticalities: The ARINC 653 APEX interface supports the ability to collocate application software of different levels of criticality.

The set of ARINC 653 APEX API provide handy and easy interface across the application and the underlying operating system and enhances developer productivity, reduce complexity and effort involved in certification.

RAID 0 on paired magnetic disk arrays

Nikola Davidović, Borislav Đorđević, *Member, IEEE*, Valentina Timčenko, *Member, IEEE*,
Slobodan Obradović, Bojan Škorić

***Abstract* – The connection of multiple secondary memory devices in RAID 0 aims to improve three performance parameters of the secondary memory system: greater storage capacity, the increase of the read data access speed and increase of the write data access speed. This paper analyses the system for storing the data on the paired arrays of magnetic disks in RAID 0 formation, with the number of queue entries for overlapped I/O, where queue depth parameter has the value of 4. The paper presents a range of the testing results and analysis for RAID 0 series for defined workload characteristics. The tests were done in the Microsoft Windows Server 2008 R2 Standard operating system, using 2, 3, 4 and 6 paired magnetic disks and controlled by Dell PERC 6/i hardware RAID controller. For the needs of obtaining the measurement results, we have used the ATTO Disk Benchmark. We have analyzed the obtained results and compared to the expected behaviours.**

Key words - HDD; secondary memory; magnetic disk; performances; RAID 0; ATTO Disk Benchmark; Windows.

I. Introduction

The tendency of different user needs for the increase of the exchanged amount of data has implicated the necessity for providing larger storage space, as well as for the development of faster access and easier management of data. Such trends have led to an inevitable increase in the risks related to the loss or/and compromise of data security. When it comes to the performance of the secondary memory, it is usually measured through three components: available capacity, data access speed and reliability while storing and keeping safe the data. Further improvements in the performance of secondary memory can be achieved either by the use of the parallel disks or by the application of some up to date technology.

The storage space is actually not a performance parameter but still can have an impact on the overall system performances. Thus some recent technological improvements have indicated need of considering storage space as one of the important aspects when designing the system storage characteristics. Despite the emergence of new technology in the production of secondary memory devices - the semiconductor memory storage SSD (Solid State Disk) [1], the magnetic drives technology HDD still plays a significant role as secondary memory, primarily thanks to its high capacity and cost per MB [2]. One of the biggest disadvantages of using magnetic disks is the achievable read and write data access speeds.

The RAID (Redundant Array of Inexpensive Disks) represents a solution where the data is stored on the disk architecture that relies on the combination of several physical disks into one logical unit. The goal is to enhance performances and increase storage capacity [3]. The performance enhancement can be achieved by the increase of the speed of read/write data operations, from and to the disk and by the introduction of specific safety improvements (fault tolerance). This methodology strongly relies on the enforcement of data redundancy. The performances and reliability improvement depend on the applied RAID configuration type. RAID technology is defined through seven (7) different levels of data storage on multiple disks, which in such a way organized present a logical storage space. Seven RAID levels, though having their descriptive names in practice, are usually referred to with their numbers [4][5]. Using the standard seven levels of RAID technology, it is possible to realize the so-called "nested" or hybrid RAID. RAID levels can be realized in two ways: hardware and software RAID.

The support for specific RAID levels can be also provided by operating systems, such as with some Windows versions, or even provided on the file system level such as when using Oracle/Solaris ZFS [6][7]. In addition, the software RAID can be also found as a stand-alone application [8].

II. Redundant Array of Inexpensive Disks – type 0

When compared to all other RAID levels, RAID 0 offers the highest degree of storage space used for storing data. In addition, this RAID level provides the best read and write performance, but it does not offer redundancy.

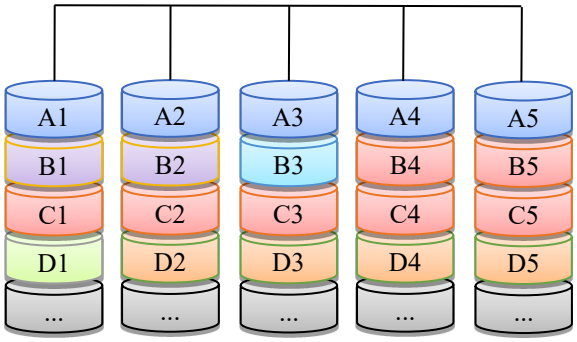

Fig. 2. RAID 0 – parallelity and competitiveness – each color is another complete piece of information

Despite the disadvantages it has, and thanks to its unmatched performance, RAID 0 is used in systems where data access speeds and storage space size play the key role. Figures 1 and 2 provide an overview of the stripping procedure and methodology applied in RAID 0. Figure 1 explains the principles of the basic stripping technique, while Figure 2 provides more detailed example of stripping several data over five different disks that are structured in RAID 0 architecture. Each exemplar data is provided in different colour, thus we can see that for instance data A is stripped on all the five disks, while data B, being smaller in size, is stripped over two disks from the array.

Ideally, we can consider that RAID 0 with N secondary memory devices (disks), when compared to the case of having just one secondary memory device, brings N times better access time for sequential and random data reading and writing. It is described with formulas 1 and 2 [9].

$$T_{seq\_rw}^{RAID-0} \approx T_{seq\_rw\_one\_seq\_m\_d}/N \quad (1)$$

$$T_{random\_rw}^{RAID-0} \approx T_{random\_one\_seq\_m\_d}/N \quad (2)$$

The practical application of the “striping by blocks”, which is typical characteristic of the RAID 0 level, works quite similar to the ideal model but still shows some inconsistencies. The Figure 1 shows procedure of storing data by dividing it and storing on 4 secondary memory devices.

The data writing or reading from the secondary memory device may have smaller or larger size than the defined block (which is essentially the data carrier). Regardless of the size of the data in the block, the secondary memory device accesses the entire block. Therefore, block size estimation is of great importance when designing RAID system. The estimation of the block size has an impact on memory space utilization and plays a significant role in maximizing the RAID performances.

When estimating the size of a block, it is necessary to take into the account the parallelism and competitiveness (Figure 2). In case when the block size is determined so that the data unit exactly occupies the defined disk memory unit (on the RAID full stripe), we can expect the increase of the speed of data access N times the number of secondary memory devices. When configured in this way, RAID 0 supports parallelism and high sequential performance. However, if the goal is to increase the competitiveness and the random access speed performance, then the size of the SU (Strip Unit) needs to be adjusted exactly to the size of the data unit.

III. Test Configuration

A. Hardware configuration

The hardware configuration is shown in Table I. The tests are carried on by the Microsoft Windows Server 2008 R2 Standard operating system. No server components or functions are added to the basic installation of the operating system, except for the necessary drivers - the RAID controller and other specific hardware drivers.

TABLE I
HARDWARE CONFIGURATION

Hardware	Specification
Server	Dell PowerEdge™ T610
RAM	8 GB, 4 x 2 GB DDR3-SDRAM
CPU Model	Intel Xeon E5530 @ 2,40 GHz (4 cores)
BIOS	Dell Inc. v.2.2.10 (9.11.2010.)
Video adapter	Matrox G200
PCIe x4 storage slot	Dell PERC 6/i
Disk	Hitachi Deskstar 250GB SATA2 x 6
PCIe x4 slot	Dell SAS 5/i
Disk	Hitachi Ultra Star 300GB SAS
OS	Microsoft Windows Server 2008 R2 Standard

The hardware RAID controller, Dell PERC 6/i, which is used for test procedures, supports devices with the second generation SATA/SAS interface (3Gb/s), while 2 SAS channels allow up to 32 connected devices. It has 256MB of its own DDR2 cache for quick storage, which can be optionally supported by a battery. It supports operation with RAID levels 0, 1, 5, 6, 10, 50 and 60. The ATTO Disk Benchmark is used for the needs of testing the impact of the RAID 0 storage size on the overall system performances.

B. ATTO Disk Benchmark

ATTO Disk Benchmark is a freeware software which helps the measurement of the storage system performance [10]. ATTO identifies the performance levels of the hard drives, solid state drives, RAID arrays, as well as the of the host connection to the attached storage. One of advantages of this benchmark is the ability to control the proces of writes and reads, while the drawback is the inability to test the random data access speed. The ATTO Disk Benchmark is compatible with Microsoft Windows and supports the File Allocation Table (FAT) and New Tehnology File System (NTFS).

Some of the setting options over which ATTO Disk benchmark can affect system performance or can isolate certain situations in practical work, are:

- *Total lenght* – this parameter specifies the test file lenght, which is the total size of data file that is created on the test drive. After finishing the testing procedure, this file is deleted.

- *Force write access* – this option allows to bypass the drive write cache. Otherwise, if this option is not selected, the drive write caching is determined by the drive settings.
- *Direct I/O* – use of the system buffering. File I/O on the test drive is performed with no system buffering or caching.
- *I/O Comparison* – compares the input and output data to detect errors. This option allows the comparison of the data from the test file with the data written on a per block basis.
- *Overlapped I/O* – this option performs queued I/O testing. The factor that specifies the I/O overlapping is the queue depth. Queue depth specifies the number of queue entries for overlapped I/O, i.e. the maximum number of read/write commands that can be executed during one time interval.
- *Neither* – do not perform overlapped I/O or I/O comparisons. The transfer requestes are sent one by one.

IV. TEST RESULTS

Certain restrictions were set in order to get as highest speed as possible for reading and writing during the test procedures.

The first limitation that is set, is to use only a specific part of the magnetic disk for testing, since magnetic discs do not have the same data transfer speed at the beginning and at the end of the disk. It is configured to use only the first 10 GB of each magnetic disks of the RAID 0 array. In this way, in the case for 2, 3, 4 and 6 magnetic disks, an entry space of 20, 30, 40 and 60 GB is obtained, respectively. Since these 10 GB make up less than 5% of the disk space, the limitations of the data rate at the beginning (in the middle of the disk) and at the end (disk circumference) of the magnetic disk has been avoided during testing.

Data caching feature could give wrong results so that they would not show the real performance of the magnetic disk itself but the performance of the cache. In addition, a significant effect may also be achieved by caching at the level of a single magnetic disk, controller or operating system itself. Because of this, when configuring each array, we have used the option to bypass the cache of the disks, as well as to generate the caching on the controller itself. In ATTO disk benchmark this is enabled by the Force Write Access and Direct I/O options, and represents the second limitation.

The third limitation is the number of multiple transfer requests which define the maximum number of read/write commands that can be executed in one time interval. The queue depth factor specifies the number of queue entries for overlapped I/O. In this way, the ability to test competitiveness is not eliminated.

In the following test we have used 1GB size NTFS partition, as the test file space was limited to 512 MB. The larger file was selected in order to get the better average values for large transfers, which can also be assumed as the sequential data access test. For the allocation unit we have used the standard size of 4kB. When testing the RAID 0 string, the three block sizes were used:

- 8kB, the smallest block that the controller supports;
- 64kB, default value;
- 1MB, the largest block that the controller supports.

Fig. 3. Reading speed a) and writing speed b) data for single magnetic disk and paired string of 2, 3, 4 and 6 magnetic disk drivers in RAID 0 at the blok size 1) KB, 2) 64 KB and 3) 1 MB

The values of SUs in the Table II are given in the first column. In the second column of the Table II we have presented the number of magnetic disks on which the tests were performed for different SUs. The test procedure starts with the evaluation of 512 bytes and ends with 8192 KB, each step dobles the data size from the previous iterration.

Figure 3.a1 shows the read speed from a single magnetic disk and for the paired array of magnetic disks RAID 0. We have used the 8 KB block size and different amounts of data, while the measurement results are shown in the Table II. The RAID 0 with two magnetic disks has provided the expected results for small amounts of data, and in accordance with formulas (1) and (2). For the small amounts of data the other RAID 0 configurations (with 3, 4 and 6 magnetic disks) have also performed with better results than the single disk, but with the queue depth factor limitation. This is one of the reasons for slighther improvements of these configurations over the RAID 0 with 2 disks.

The figure 3.a1 and Table II show better results for RAID 0 with 3, 4 and 6 discs, when compared to RAID 0 with 2 disks, which appears with the raise of the data transfer size above 8KB. The queue depth factor effect, the stripe unit size and the data size had the mayor impact to the obtained results.

It is notable from Table II and figures 3.a1, 3.a2 and 3.a3 that RAID 0 with 2 paired disks has the best results (ratio MB/s and number of disk) for small data reads, regardless the size of the SU. In addition, it is noticeable that when increasing the SU size, there is a slight data read speed decrease, while for the larger amounts of data there is a significant improvement of the data read speed. RAID effects are noticeable only for the cases where the size of the RAID block is 64KB or 1MB (figures 3.a2, 3.a3, 3.b2 and 3.b3 and Table II). The SU size impact is evident, as for the case of the larger amount of data the obtained results are much better than in the case of the block size of 8KB.

From figure 3.b1 and Table II we can have similar conclusions as in the case shown on the figure 3.a1, but with more degradation effects due to the fact that all the configured RAID 0 systems have poorer writing performances than the single magnetic disk for the larger amount of data. This behavior is the result of the queue depth factor effect, the size of the SU and the data size. In booth cases shown on the figures 3.a1 and 3.b1, the depth factor effect can not compensate for the losses caused by a bad selection of the SU size.

When comparing the obtained values (Table II) for the data size of 64KB, the improvements relative to a single magnetic disk during reading, for the maximum amount of data transferred, are 200%, 284%, 364% and 554%. For writing operation we have gained 204%, 302%, 407 % and 599% for 2, 3, 4, and 6 paired magnetic disks in RAID 0, respectively. Similar but somewhat minor improvements are obtained for 1 MB block size. When comparing the results for the block size of 64KB and 1MB (Table II), it is noticeable that the increase to the 1MB block size does not significantly improve the performances when compared to the improvements gained with 64kB block size increase. The performance gain is approximately equal when comparing read and write speeds for blocks of the size 64KB and 1MB. Although the improvements for a block size of 64KB and 1MB are better when compared to the single magnetic disk, as well as with RAID 0 with a block size of 8 KB, it is noticeable that they are smaller than in the ideal case (formula 1).

In all the performed tests, it is noticeable that the writing performance results are far worse than for reading. One of the reasons for these results is that during the measurement, the force write access option was applied. It obviates the use of caching on a disk or controller when writing data, while reading the effects of caching are expressed.

V. CONCLUSION

In this paper we have analysed the RAID 0 data storage system on paired magnetic disk arrays. The testing results have shown that the RAID 0 performance depends on four factors: queue depth, amount of data, SU size and the number of disks. Inadequate block size selection for a RAID 0 string can significantly degrade the performance of the system. In the case of the adequate configuration, RAID 0 shows a direct gain in performance with an increase of the number of disks (formulas 1 and 2). The performance gain is approximately the same for both data reading and writing operations. By analysing the obtained results, it is possible to conclude that when using RAID 0 series it is possible to achieve better performances for reading and writing operations for the semiconductor disks, but there is also the issue of increased risk of data loss.

Ažuriranje Android operativnog sistema upotrebom Push VoD tehnologije

Miloš Ivanković, dr Ilija Bašičević, MSc Goran Stupar

***Apstrakt*—U ovom radu prezentovano je jedno rešenje ažuriranja korisničkih Set-Top Box uređaja zasnovanih na Android operativnom sistemu u slučaju ograničenog pristupa ili potpune nemogućnosti pristupa internet mreži. Kao specifična okolnost koja se može javiti u slučaju distribucije digitalnog televizijskog signala, ovom prilikom je rešena prenosom podataka neophodnih za ažuriranje uređaja putem prenosnog toka kojim se distribuira digitalni televizijski signal. Ovaj rad predstavlja funkcionalno rešenje primenljivo i u drugim sličnim implementacijama obrade prenosnog toka digitalnog televizijskog signala.**

***Ključne reči*—Digitalna televizija (DTV), Android OS, Push VoD (video sadržaj na zahtev), Set-Top Box (STB)**

I. Uvod

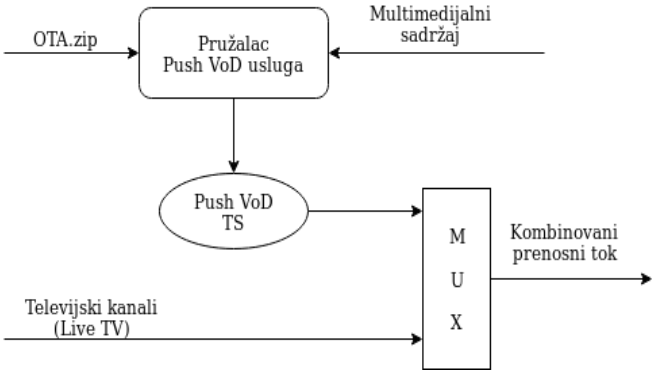
Mnogi moderni STB uređaji zasnovani su na Android platformi. Periodično ažuriranje platforme ključno je za ispravno funkcionisanje uređaja. Novim izmenama sistema ispravljaju se greške u radu, unapređuje sistem zaštite, unapređuje stabilnost uređaja u celini a ovde su uključene i izmene u domenu grafičke korisničke sprege. Naročito su od velikog značaja izmene sistema zaštite koje vremenom postaju sve podložnije napadima.

Posebno je od značaja mogućnost ažuriranja udaljenih uređaja odnosno uređaja koji se već nalaze u upotrebi. Sa razvojem i rastom popularnosti pametnih prenosivih uređaja poput mobilnih telefona i tableta raste potreba za redovnom nadogradnjom postojećih uređaja. Naročito popularna tehnologija u ovom domenu jeste OTA (eng. Over-the-air). Osnovna ideja jeste distribucija specijalizovanih OTA paketa podataka koje u sebi sadrže izmene koje treba primeniti. Standardni način za pribavljanje ovakvih paketa jeste posredstvom internet konekcije kojom se korisniku podaci dostavljaju. Međutim u slučaju digitalne televizije može se javiti specifična situacija u kojoj u određenoj regiji postoji dovoljno dobra razvijena televezijska ali ne i internet infrastruktura. U tom slučaju krajnji korisnici STB uređaja mogu uživati u konzumiranju A/V sadržaja međutim imaju ograničen pristup internetu ili pak uopšte ne postoji mogućnost priključenja na internet. Tada je rešenje moguće naći u integraciji OTA paketa sa standardnim televizijskim signalom. Ovakav pristup zahteva prilagođavanje svih slojeva programskog koda koji se bave obradom digitalnog televizijskog signala, kao i izmene strukture samog digitalnog signala opisanih u narednim poglavljima.

Push Vod predstavlja mogućnost dobavljanja multimedijalnog sadržaja na izričit korisnički zahtev. Pored toga korisnik se dostavljaju i dodatne informacije vezane za sadržaj pa je tako korisnik u mogućnosti da sazna nešto više o sadržaju što je od posebnog značaja ukoliko se od korisnika zahteva dodatna naplata ovakve usluge.

II. Arhitektura rešenja

Posao stvaranja prenosnog toka poveren je specijalizovanim kompanijama koje se bave isporukom televizijskog sadržaja. Prenosni tok u sebi sadrži kako sadržaj koji se emituje u realnom vremenu, tako i sadržaj koji je predmet usluge Video na zahtev (eng. Video On Demand). Ranije pomenuti OTA paketi se dostavljaju ovakvim kompanijama koje ih potom uključuju u transportni tok koji korisnik može preuzeti. OTA paketi se u transportni tok uključuju zajedno sa sadržajima namenjenim preuzimanju na zahtev. Na narednom dijagramu dat je sažet pregled ovakvog rešenja.



Sl. 1. Šematski prikaz formiranja prenosnog toka koji se isporučuje korisnicima

Trasportni tok nastao kombinovanjem multimedijalnog sadržaja namenjenog preuzimanju na zahtev i OTA podataka na dijagramu je označen kao Push Vod TS. Dalje se on kombinuje sa živim televizijsim signalom odnosno televizijskim sadržajem namenjenim emitovanju u realnom vremenu. Ova dva toka se potom kombinuju upotrebom namenske specijalizovane jedinice nazvane multiplekser. Kao

Miloš Ivanković – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: ivankovicm02@gmail.com).

Dr Ilija Bašičević – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: ilibas@uns.ac.rs).

Msc Goran Stupar – Istraživačko-razvojni Institut RT-RK, Novi Sad, Srbija (e-mail: goran.stupar@rt-rk.com).

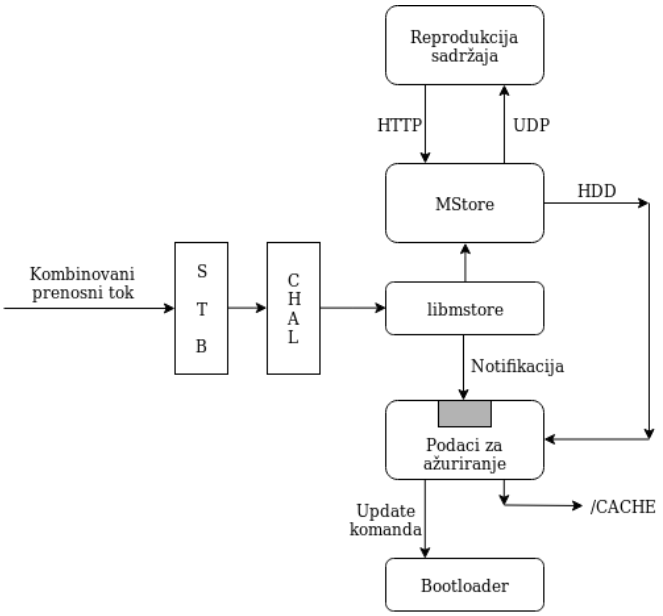
izlaz ovog modula (bez obzira da li je hardverski ili softverski implementiran) dobijamo kombinovan prenosni tok koji se potom isporučuje krajnjem korisniku.

Međutim ažuriranje nije potrebno obavljati svaki put kada korisnički uređaj u prenosnom toku prepozna OTA sadržaj nego se korisniku dodatno signalizira trenutak kada ažuriranje treba izvršiti. Kako se unutar prenosnog toka zajedno sa audio i video sadržajem za reprodukciju prenose i dodatni podaci vezani za televizijski sadržaj u vidu specijalizovanih tabela podataka, to znači da je dozvolu za ažuriranje moguće dostaviti upotrebom standardom predviđenih polja već postojećih tabela. DVB standard jasno propisuje koja polja mogu činiti jednu tabelu kao i redosled pojavljivanja svih polja u tabeli. Pri tome su pojedina polja označena kao opciona te se samim tim ne moraju koristiti prilikom isporuke prenosnog toka. Tako na izlazu dobijamo prenosno tok podataka koji se od do sada korišćenog razlikuje u tome što sadrži dodatne podatke u vidu OTA paketa kao i dodatne signalizacione informacije postavljenje u opciona polja tabela dodatnih podataka. Svi oni sačinjavaju prenosni tok koji se isporučuje korisniku.

STB uređaj poseduje namenski prilagodni programski sloj čiji je zadatak prihvat, obrada i dalja distribucija digitalnog prenosnog toka. Sastoji se od tri celine i to: sloja zaduženog za komunikaciju sa fizičkom arhitekturom uređaja, sloja za obradu digitalnog prenosnog toka i na kraju sloja zaduženog za komunikaciju sa Android platformom. Najniži sloj zadužen za komunikaciju sa fizičkim komponentama zadužen je za prihvat Push VoD sadržaja ali i ostalog digitalnog sadržaja (filtriranje metapodataka, audio i video komponenata prenosnog toka). Ovo je moguće zbog toga što se prenosni tok sadrži od niza paketa jedinstveno označenih nizom identifikacionih brojnih vrednosti. Tako je moguće iz prenosnog toka dobaviti samo pakete od interesa. Prikupljanje delova OTA paketa kao i formiranje jedinstvene datoteke povereno je korisničkoj biblioteci libmstore. Načelno ova korisnička biblioteka ima za zadatak isporuku audio i video sadržaja dobavljenog na zahtev koji se potom isporučuje korisničkoj aplikaciji. Ovaj sadržaj se potom može reprodukovati na zahtev korisnika. Proširenjem ovog korisničkog servisa omogućen je prihvat OTA podataka. Jedan od osnovnih zadataka pomenute korisničke biblioteke jeste i slanje obaveštenja višim programskim slojevima o uspešnom prispeću Push VOD sadržaja u trenutku kada je sav digitalni sadržaj preuzet iz prenosnog toka. Ovaj mehanizam je proširen time što sada postoji mogućnost slanja obaveštenja o prihvatu OTA paketa.

Ranije je pomenuto da se korisničkom STB uređaju posredstvom tabela sa metapodacima signalizira trenutak kada je uređaj potrebno ažurirati. Programski sloj zadužen za komunikaciju sa elementima fizičke arhitekture je zadužen za upravljanje komponentama zaduženim za filtriranje metapodataka prenosnog toka. Među ovim podacima nalaze se brojne standardne DVB tabele (PAT, PMT, SDT, TOT, TDT…). Jedna od ovih tabela zadužena mrežnu identifikaciju namenski je proširena signalizacionim podacima u okviru Linkage descriptor-a na osnovu kojih se odobrava ili ne odobrava ažuriranje. Nakon pristizanja tabela se na osnovu njihovih jedinstenih identifikacionih brojnih oznaka iz prenosnog toka izdvaja NIT tabela. Njen sadržaj se potom iščitava uz pomoć programskog sloja zaduženog za obradu prenosnog toka. Kako je NIT tabela namenski proširena signalizacionim podacima, tako je bilo potrebno namenski proširiti programske module namenjene iščitavanju sadržaja tabela i na taj način omogućio pristup i odredio sadržaj signalizacionih podataka. Pristizanje ove tabele je periodično, što je predviđeno DVB standardom. Kada je ažuriranje dozvoljeno tada se unapred registrovanom metodom javlja ostatku sistema da je ažuriranje neophodno. Nakon toga je dobavljeni OTA paket je potrebno prebaciti u odgovajući keš direktorijum bootloader platformskog alata. Finalni korak predstavlja prosleđivanje komande za ažuriranje bootloader komponenti nakon čega se pokreće proces ažuriranja sistema koji za ulazni parameter ima prethodno pomenuti OTA paket.

Na narednom dijagramu dat je sažet pregled toka obrade na klijentskom STB uređaju.



Sl. 2. Šematski prikaz koraka neophodnih za pokretanje ažuriranja sistema

III. NAMENSKA PROŠIRENJA POSTOJEĆEG REŠENJA

Kao što je ranije pomenuto, do određenih metapodataka dolazimo filtriranjem ulaznog prenosnog toka podataka. Na ovaj način možemo izdvojiti i NIT tabele. Jednom preuzeta, ona se potom prosleđuje programskom modulu namenjenom njenom iščitavanju. Ovaj modul je bilo neophodno proširiti kako bi bile uzete u obzir izmene nastale dodavanjem ranije pomenutih signalizacionih podataka.

Potrebno je bilo implementirati mehanizam kojim bi se drugim programskim modulima moglo javiti da je ažuriranje uređaja dozvoljeno. U ovu svrhu implentiran je niz povratnih poziva koji se aktiviraju svaki put kada signalizacioni podaci pristignu.

mstore predstavlja korisničku biblioteku čija je osnovna funkcionalnost prosleđivanje Push Vod sadržaja Mstore korisničkoj aplikaciji koja ih potom skladišti u trajnoj memoriji uređaja na unapred određenoj lokaciji. Ciljna aplikacija koja je namenjena reproduckiji video sadržaja u ovom slučaju nema pravo pristupa OTA podacima. Kompletna funkcionalnost vezana za rad sa OTA i signalizacionim podacima dodata je ovoj korisničkoj biblioteci.

Prethodno su opisani programski slojevi koji za cilj imaju reagovanje na određene događaje u sistemu kao i slanje odgovarajućih obaveštenja višim programskim slojevima. Stoga je bilo neophodno razviti namenski programski modul koji će predstavljati krajnju putanju ovih obaveštenja. Na prethodnom dijagramu je ovaj blok predstavljen kao blok namenjen skladištenju podataka za ažuriranje i koji ima dvojaku ulogu. Sa jedne strane se nalazi u komunikaciji sa MStore aplikacijom od koje pristižu obaveštenja o tome da je OTA paket pristigao, uspešno sastavljen i sačuvan u unapred definisanoj lokaciji trajne memorije. Komunikacija se odvija putem UDP mrežnog protokola. Po pristizanju obaveštenja, OTA podaci se kopiraju u /CACHE direktorijum bootloader alata. Sa druge strane se opet posredstvom UDP protokola dostavlja obaveštenje o pristizanju dozvole za pokretanje ažuriranja. Ovo za rezultat ima prosleđivanje komande za pokretanje ažuriranja bootaloder alatu. Nakon toga se unapred određenim procedurama operativni sistem ažurira a korisnik je u mogućnosti da nakon automatskog ponovnog pokretanja uređaja koristi novu verziju operativnog sistema.

IV. Zaključak

Moderne implementacije DVB standarda praćene savremenom mrežnom infrastrukturom omogućavaju ažuriranje operativnog sistema korisničkog uređaja posredstvom mrežne infrastrukture. Odstupanje od ovakvog pristupa sa sobom nosi brojne poteškoće s obzirom da podrazumeva rešenja koja nisu deo uobičajene prakse. Izmene obuhvataju veći broj modula raspoređenih u različitim programskim slojevima sistema za distribuciju i obradu digitalnog televizijskog signala, razvijenih u različitim tehnologijama. Implementacija takvog rešenje zahteva saradnju nekoliko ne samo timova nego i kompanija što dodatno otežava implementaciju. Upravo takav jedan problem predmet je uspešne implementacije opisane u ovom radu.

Abstract

In this paper we present one solution for updating user owned Set-Top Box device based on the Android operating system in case of limited access or complete inability to acces the Internet. As a specific circumstance that occurs in the case of the distribution of a digital television signal, on this occasion it is solved by the transmission of the data necessary for updating the device through the tranpost stream used to distribute the contents of the digital television signal. This paper presents a functional solution applicable also in other similar implementations of the processing of the transport stream of the digital television signal.

Android operating system updating with the use of Push VoD technology

Ažuriranje Android baziranog digitalnog TV prijemnika u slučaju onemogućene internet konekcije

Nataša Bogdanović, Ilija Bašičević, Goran Stupar

[1]

***Apstrakt*—Ovaj rad predstaviće jedno od rešenja ažuriranja korisničkih Set-Top Box uređaja zasnovanih na Android operativnom sistemu u uslovima kada je internet konekcija ograničena ili onemogućena. Nedostatak kvalitetne internet konekcije predstavlja jedan od mogućih problema koji se javljaju prilikom distribucije digitalnog televizijskog signala. Rešenje koje je predstavljeno u ovom radu koristi specijalne kontrolne strimove koji sadrže signalne tabele kako bi se kontrolisalo vreme ažuriranja.**

***Ključne reči*—Digitalna televizija (DTV), Android OS, OTA (eng. Over-the-air), Set-Top Box (STB)**

I. Uvod

U današnje vreme, televizija je svakako jedna od tehnologija koje su u velikoj meri pod uticajem tehnološkog razvoja. Kada se govori o tehnološkom razvoju bilo koje tehnologije, to podrazumeva pre svega prolazak određene tehnologije kroz niz procesa promena i unapređenja. Razvoj televizije može da se posmatra kroz mnoge različite aspekte kao što su, na primer, razvoj načina emitovanja, promene i unapređenja u tehnikama emitovanja slike, razvoj prenosnog puta i mnogi drugi. Razvoj televizije je svakako usko povezan sa razvojem televizijskih prijemnika i usmeren je najviše na prilagođavanje zahtevima tržišta koji se sve brže menjaju.

Promena koja je najviše doprinela razvoju i ekspanziji televizije je promena prenosa signala. Pod promenom prenosa signala podrazumeva se prelazak sa analognog na digitalni signal, što uvodi novi pojam u televizijskoj industriji,a to je pojam digitalne televizije. Pojava i razvoj digitalne televizije donosi mnoge prednosti, a samim tim otvara i nove pravce i mogućnosti za dalji razvoj, ali uz to donosi i mnoge probleme na tržištu. Smena analogne televizije digitalnom predstavljala je najveći problem za korisnike čiji prijemnik nije mogao da obradi digitalni signal. Da bi se ovaj problem rešio, televizijska industrija je predstavila novi proizvod, STB (set-top-box) uređaje. Pojava STB uređaja na tržištu omogućila je korisnicima prednosti koje digitalna televizija pruža.

Potreba da se u što većoj meri korisnicima obezbede televizijski sadržaji visokog kvaliteta predstavlja veliki izazov za televizijsku industriju. Prednost digitalnog prenosa podataka se ogleda pre svega u tome što obezbeđuje sliku i zvuk boljeg kvaliteta. Kod digitalnog prenosa više ne postoji problem ometanja interferencijom sa drugim signalima, čak i kod prenosa slike i zvuka na velikom rastojanju. Sadržaji koji se isporučuju putem digitalnog prenosa isti su kao na izvoru emitovanja. Postoji više različitih digitalnih standarda koji se koriste u različitim delovima sveta. Standardi koriste MPEG-2 tehnologiju za audio i video kodiranje i multipleksiranje kako bi se omogućio odgovarajući protok podataka potrebnih za podršku televizije visoke rezolucije (engl. High Definition Television, HDTV) ili televiziju standardne rezolucije (engl. Standard Definition Television, SDTV).

Prijemnik digitalnog televizijskog signala je uređaj koji je zadužen za konverziju digitalnog televizijskog signala da bi isporučeni sadržaj mogao biti prikazan na televizorima. Prijemnik može biti ugrađen ili odvojeni uređaj. Prijemnici koji su odvojeni uređaji nazivaju se STB uređaji. Uloga STB uređaja je pre svega prijem signala, ali razvojem televizijske industrije ovo postaje uređaj koji ima sve više osobina personalnog računara i multimedijalnog uređaja. Najvažnije funkcionalnosti STB uređaja su obrada emitovanog signala, zaštita signala od neovlašćenog pristupa, obrada audio i video podataka, kao i mogućnost interakcije sa korisnikom.

II. Definicija problema

Jedan od problema koji svakako prate razvoj u televizijskoj industiji je i ažuriranje udaljenih uređaja. Pojam udaljeni uređaji se najviše odnosi na uređaje koji su već u korisničkoj upotrebi. Sve brži razvoj u ovoj oblasti donosi potrebu za unapređenjem već postojećih uređaja, kako bi korisnici mogli da dobiju najnovije promene i unapređenja u što kraćem roku. Kao jedno od najvažnijih rešenja ovog problema predstavlja se OTA (eng. Over-the-air) tehnologija. Ova tehnologija podrazumeva distribuciju specijalizovanih OTA paketa podataka. OTA paketi sadrže unapređenja koja treba da se primene na već postojeće uređaje. Najrasprostranjeniji način korišćenja OTA paketa je dobavljanje istih putem internet konekcije. U najvećem broju slučajeva ovakav pristup je moguće i najjednostavnije rešenje, ali postoje i situacije u kojima je potrebno unaprediti određeni uređaj bez prisustva

Nataša Bogdanović – Naučno-istraživački institut RT-RK, Narodnog Fronta 23a, 21000 Novi Sad, Srbija (e-mail: natasa.bogdanovic@rt-rk.com).

Goran Stupar – Naučno-istraživački institut RT-RK, Narodnog Fronta 23a, 21000 Novi Sad, Srbija (e-mail: goran.stupar@rt-rk.com).

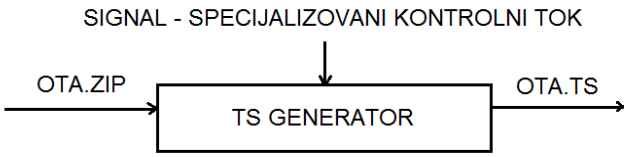
Ilija Bašičević – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: ilibas@uns.ac.rs).

internet konekcije. Ovakve situacije mogu da zahvate veliki broj korisnika, pa je veoma važno imati rešenje i u ovakvim okolnostima.

Jedno od rešenja predstavlja integraciju OTA paketa sa standardnim televizijskim signalom. Integracija OTA paketa sa standardnim televizijskim signalom dovodi do problema kontrolisanja vremena ažuriranja uređaja.

III. ARHITEKTURA REŠENJA

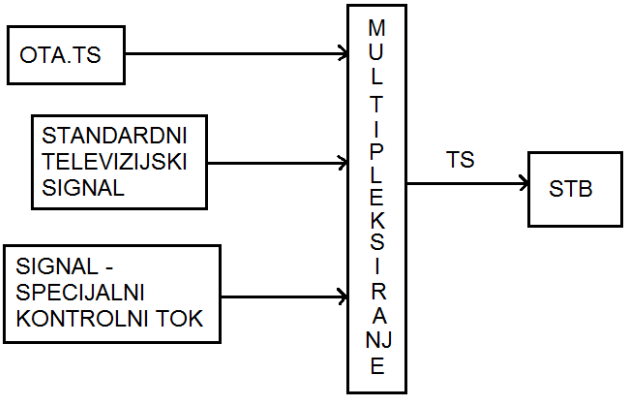
Osnovna ideja rešenja datog problema je upotreba specijalnih kontrolnih tokova koji sadrže signalne tabele. Postoje dva načina da se ovakvi kontrolni tokovi uključe u standardni televizijski signal. Prvi način, koji se koristi samo za testiranje, podrazumeva uključivanje kontrolnog toka prilikom prilagođavanja OTA paketa za integraciju sa standardnim televizijskim signalom. Ovakvo rešenje prikazano je na Slici 1.



Slika 1

Da bi se OTA paket mogao integrisati sa standardnim televizijskim signalom, potrebno je izvršiti konverziju paketa u prenosni tok. Ovo rešenje uključuje specijalizovani kontrolni tok prilikom konverzije. TS generator generise DSM-CC sekcije. DSM-CC (Digital Storage Media – Command and Control) je novi ISO/IEC standard za isporuku multimedijalnih usluga širokog obima. DSM-CC tabele u sebi sadrže komande koje se šalju prijemniku. Ovaj protokol koristi klijent-server model komunikacije i koristi se za kontrolu prijema signala. Protokol između ostalog sadrži uobičajene funkcije ubrzanog premotavanja, pauziranja i sl. Kao što je već navedeno, ovo rešenje se koristi samo za testiranje, pa je samim tim drugo rešenje mnogo značajnije jer ima širu upotrebu.

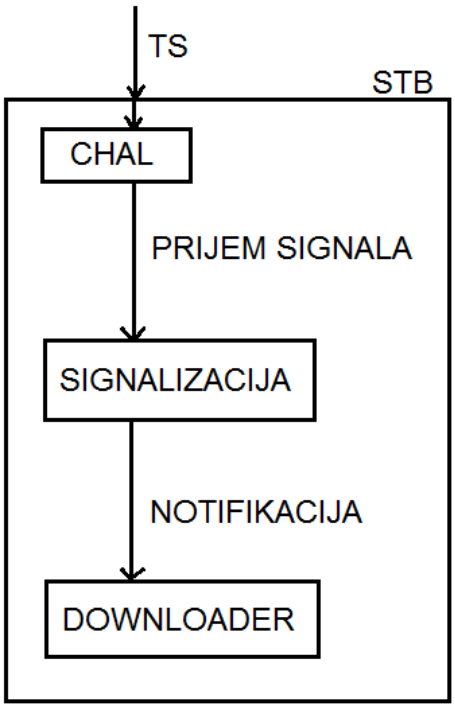
Drugo rešenje navedenog problema podrazumeva uključivanje specijalizovanog kontrolnog toka za signalizaciju prilikom multipleksiranja. Multipleksiranje je proces kombinovanja MPEG-2 elementarnih tokova u jedinstveni informacioni tok u skladu sa definisanim formatom. Multipleksiranje se koristi za integraciju OTA.TS sa standardnim televizijskim signalom i u ovom slučaju sa specijalnim kontrolnim tokom za signalizaciju. Kao rezultat multipleksiranja dobija se jedinstveni prenosni tok koji će da prima prijemnik na STB. Ovaj process je prikazan na Slici 2.



Slika 2

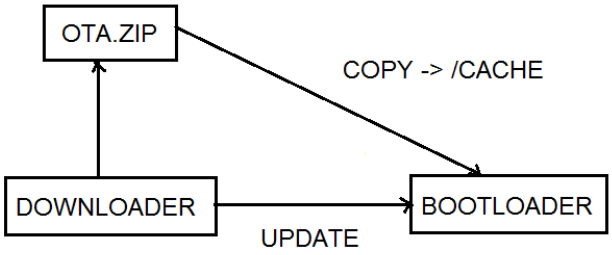
Kada prenosni tok generisan na ovakav način stigne do STB prijemnika, potrebno je obezbediti odgovarajuće rešenje za primenu dobijenih podataka. Kako ažuriranje nije potrebno uraditi uvek kada uređaj prepozna OTA paket, specijalni kontrolni tokovi koji su uključeni u prenosni tok će signalizirati korisniku kada je potrebno izvršiti ažuriranje uređaja. Korisnički STB urežaj u sebi sadrži programski sloj koji prima i vrši dalju obradu i distribuciju primljenog prenosnog toka. Najniži programski deo – CHAL koristi se za komunikaciju sa fizičkom arhitekturom STB uređaja i služi za prijem digitalnog sadržaja u vidu prenosnog toka. Kako je prenosni tok sastavljen od niza paketa koji su identifikovani jedinstvenim brojnim vrednostima, moguće je pristupiti konkretnim paketima iz prenosnog toka koji su potrebni. Nakon prijema paketa dalje se obavlja obrada i distribucija određenih podataka.

U ovom konkretnom slučaju, kada posmatramo OTA paket koji je primljen putem prenosnog toka, treba dobaviti informaciju o tome da li je ažuriranje potrebno. Za to su zaduženi specijalni kontrolni tokovi koji su takođe poslati putem prenosnog toka. Oni sadrže signalne tabele u kojima se nalaze informacije o tome da li je ažuriranje potrebno i kada. Ukoliko stigne informacija da je ažuriranje potrebno, uređaj će primiti signal i poslati notifikaciju posebnom programskom sloju prilagođenom za dobavljanje podataka – DOWNLOADER. Slika 3 prikazuje ovaj proces, od prijema podataka na korisnički STB uređaj do slanja notifikacije za ažuriranje. Slika 3 predstavlja nastavak na process prikazan na Slici 2.



Slika 3

Downloader služi za preuzimanje OTA paketa za ažuriranje koji je poslat preko prenosnog toka. Koristi DSM-CC protokol koji se sastoji od data carousel i object carousel dela. Data carousel se koristi za slanje podataka preko prenosnog toka, a object carousel je njegovo proširenje koje se koristi za slanje fascikli sa fajlovima i slično. Dowloader je zadužen da iz primljenog prenosnog toka koji je TS (engl. Transport stream) izdvoji OTA paket koji sadrži podatke za ažuriranje. Da bi se OTA paket mogao primeniti na korisnički uređaj, downloader će izdvojiti OTA.ZIP iz prenosnog toka. Kada je ovaj proces završen, OTA podaci će se kopirati u /cache particiju bootloader alata. Bootloader alat će primiti notifikaciju za pokretanje procesa ažuriranja. Nakon ažuriranja i automatskog ponovnog pokretanja uređaja korisnik može da koristi novu verziju operativnog sistema. Ovaj proces je prikazan na Slici 4.



Slika 4

IV. IDEJE ZA BUDUĆI RAZVOJ

Opisano rešenje još uvek nije u potpunosti implementirano i pojedini delovi u ovom radu su samo idejno i teorijski predstavljeni, pa se kao prvi sledeći korak svakako mora posmatrati implementacija. Nakon završene implementacije naredni korak je testiranje i analiza, kao i poboljšanja na osnovu dobijenih rezultata testiranja. U prethodnom odeljku opisana su dva načina za integraciju signala u prenosni tok. Kao što je već navedeno, prvo rešenje će svoju primenu naći prilikom testiranja downloadera.

Dalji razvoj mogao bi doneti i širu primenu opisanog rešenja. Ovakav pristup koji ne zavisi od internet konekcije može da se iskoristi ponovo prilikom rešavanja nekog drugog problema.

V. ZAKLJUČAK

U ovom radu je opisano jedno od rešenja problema ažuriranja korisničkih STB uređaja koji su već u upotrebi kada je onemogućena internet konekcija. Na ovaj način korisnicima je obezbeđeno da prate trendove usavršavanja proizvoda televizijske industrije koje koriste. Opisano rešenje će učiniti ažuriranje uređaja mnogo jednostavnijim i doneće velikom broju korisnika nove mogućnosti.

ZAHVALNICA

ABSTRACT

This paper presents a solution for updating Set-Top Boxes based on the Android operating system in circumstances where the Internet connection is limited or disabled. The lack of a quality internet connection is one of the possible problems that occur when distributing a digital television signal. The solution presented in this paper uses special control streams that contain signal tables to control the update time.

Realizacija upravljačke korisničke sprege za kontrolu softvera za snimanje i uređivanje zvuka

Milan Vuletić, Sergej Furtula, Jelena Kovačević, *Member, IEEE*

***Apstrakt*—Ovim radom je predstavljen jedan od načina unapređenja ispitnog okruženja za ispitivanje uređaja namenjinih za dekodovanje, obradu i reprodukciju Audio sadržaja pomoću programskog alata Audacity. Ova ispitivanja se vrše u dve faze, prva faza na nivou procesora a druga na nivou proizvoda. Ispitno okruženje za ispitivanje obično koristi APx (Audio Precision) merni uređaj, a unapređenje zapravo pretstavlja integraciju Audacity programskog alata u ova okruženja. Takođe, za potrebe dodatne automatizacije ispitnih slučajeva, realizovano je automatsko izvršavanje komandi za reprodukovanje, snimanje, generisanje i analiziranje audio zapisa.**

Rezultat ovog unapređenja se ogleda u smanjenju greške tokom ispitivanja i analize, izazvane „ljudskim faktorom“ kao i smanjenju vremena potrebnog za izvršavanje celokupne procedure.

***Ključne reči*—Automatizacija, programski alati, ispitivanje.**

I. Uvod

Sa porastom zahteva u području audio i video tehnologije, javlja se potreba za sve efikasnijim i komplikovanijim uređajima za audio i video obradu. Razvoj audio tehnologije direktno utiče na razvoj hardverskih jedinica, a još više na razvoj softverske podrške. Kako bi se na tržištu pojavio u što kraćem roku, nov audio uređaj, potrebno je obaviti i odgovarajuća ispitivanja tog uređaja sa ciljem zadovoljenja različitih sertifikata i željenog kvaliteta od strane samog proizvođača. U cilju bržeg i kvalitetnijeg ispitivanja audio uređaja potrebno je omogućiti automatizovano radno okruženje čime se postiže i smanjenje faktora “ljudske greške“. Ispitivanje audio uređaja se obično izvršava kroz dve faze, ispitivanja na nivou procesora koji direktno vrši audio obradu i na nivou gotovog proizvoda.

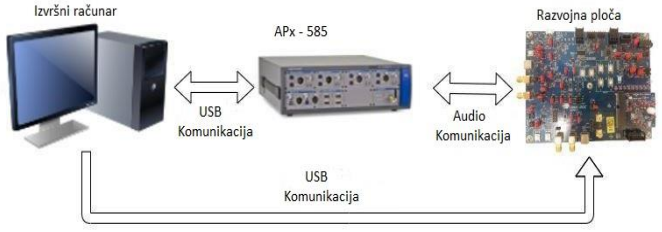
Razvoj softvera za dekodovanje, obradu i reprodukciju audio sadržaja obično se vrši na razvojnoj ploči sa odgovarajućim procesorom, odnosno arhitekturom prilagođenom za obradu audio signala (DSP). U prvoj fazi ispitivanja ispitni slučajevi pokrivaju scenarije koji za cilj imaju da verifikuju funkcionalnost softverske podrške na procesorkom nivou. U drugoj fazi se verifikuju signali na sistemskom nivou i ispituje se odziv uređaja kao proizvoda. Ispitivanje ispravnosti na nivou procesora i na nivou proizvoda razlikuje se u načinu verifikovanja (od načina dekodovanja, obrade pa sve do reprodukcije audio sadržaja), te su za te potrebe razvijene posebne ispitne procedure od samih IP providera, koji razvijaju i pružaju audio tehnologije (Dolby, DTS).

Razvoj proizvoda podrazumeva softversku podršku i QA (“Quality Assurance“) podršku. Neke procene govore da se za ispitivanje i pronalaženje grešaka utroši i do 50% ukupnog vremena potrebnog za razvoj [1]. Da bi uređaj u što kraćem roku ušao u fazu proizvodnje veoma je bitno da u fazi razvoja softverske podrške verifikacija bude usklađena sa razvojem. Postizanjem što većeg nivoa automatizacije, kako ispitivanja tako i analize rezultata, omogućava se brži razvoj softvera i brži razvoj uređaja [2].

U ovom radu je analizirano jedno rešenje automatizacije ispitnih okruženja za audio i video uređaje. U njemu je predstavljen jedan od načina unapređenja kroz automatizaciju ispitnih procedura sa ciljem da se omogući brži razvoj i sistemska integracija softvera za audio obradu u audio i video uređajima.

II. Opis ispitnog okruženja

Ispitno okruženje je razvijeno unutar Istraživačkog-razvojnog Instituta „RT-RK“ pod nazivom UTS (Unified Test Setup), koje sadrži program za pokretanje ispitnih slučajeva, neophodne sistemske biblioteke koje se koriste prilikom ispitne procedure i potrebne alate za obradu rezultata. Na Sl. 1 je prikazana osnovna postavka UTS-a:



Sl. 1 – Prikaz ispitnog okruženja

Kako se vidi na Sl. 1, ispitno okruženje se sastoji od izvršnog računara, mernog uređaja “APx-585 multichannel audio analyzer“ proizvođača “Audio Precision“ (u daljem tekstu audio analizator) i razvojne ploče na kojoj se izvršava softver koji se verifikuje. Na izvršnom računaru se pokreće Audio Precision ispitno okruženje audio analizatora. Audio analizator ima mogućnost reprodukucije i snimanja audio zapisa. Razvojna ploča simulira prisustvo audio uređaja sa USB konekcijom i na njoj se izvršava softverska podrška koja je predmet ispitivanja.

Milan Vuletić – Istraživačko-razvojni Institut RT-RK, Novi Sad, Srbija (e-mail: Milan.Vuletic@rt-rk.com)

Sergej Furtula – Istraživačko-razvojni Institut RT-RK, Novi Sad, Srbija (e-mail: Sergej.Furtula@rt-rk.com)

Jelena Kovačević – Fakultet Tahničkih Nauka, Odsek za računarsku tehniku i računarske komunikacije, Novi Sad, Srbija (e-mail: Jelena.Kovacevic@rt-rk.com)

Ispitni slučajevi u okviru UTS-a se pokreću kroz Audio Precision softvreske podrške za audio analizator [3]. U okviru UTS-a analiza rezultata je mogla biti izvršena vizuelno ili preslušavanjem audio zapisa. Prilikom izvršavanja ispitnih procedura u okviru ispitnog okruženja, dolazilo je do sledećih problema:

- uticaj subjektivnog aspekta u odlučivanju da li je ispitni slučaj uspešan (PASS), neuspešan (FAIL) ili nedefinisan (UNRESOLVED),
- ručno pokretanje koje kao posledicu ima duže vreme izvršavanja same ispitne procedure.

A. Opis unapređenog ispitnog okruženja

Unapređenje ispitnog okruženja se ogleda u korišćenju programskog alata Audacity, odnosno iskorišćenju njegovih funkcionalnosti kako bi se povećao nivo automatizacije, a samim tim smanjila interakcija QA inženjera.

Programski alat Audacity je pre svega besplatan, veoma je korišćen za uređivanje audio zapisa i jednostavan za korišćenje [4]. Da bi se ovaj programski alat uspešno koristio u procesu ispitivanja, neophodno je nadograditi njegov aplikativni deo kako bi se koristile komande za reprodukovanje, snimanje i generisanje audio zapisa. Od verzije 2.2.2 programskog alata Audacity, korisnicima je omogućeno da pristupe aplikativnom delu samog alata i da putem komandne linije proslede parametar za reprodukovanje, snimanje, generisanje, grafičku analizu u frekventom domenu i za reprodukovanje višekanalnih audio zapisa. Pored svih pogodnosti koje Audacity omogućava, Audacity takođe ima podršku i za ostale operativne sisteme (Windows 7, Windows 10, Linux i Mac OS X). Takođe, Audacity ima mogućnost i grafičkog prikaza što je pogodno za eventualno ručno pokretanje pojedinačnih slučajeva ili za analizu rezultata. Smanjenjem faktora ljudske greške je smanjena mogućnost reprodukovanja pogrešno prosleđenog audio zapisa, kao i smanjen subjektivni osećaj da li je ispitni slučaj uspešan, neuspešan ili pak nedefinisan.

Za realizaciju komunikacije Audacity-a sa softverskom podrškom audio analizatora a time i generalno sa UTS-om, neophodno je unutar Audacity-a omogućiti modul pod nazivom "mod-script-pipe". Mod-script-pipe je komunikacioni kanal koji služi za pristupanje aplikativnom delu Audacity softverskog paketa preko koga se takođe prosleđuju parametri kroz komandnu liniju. Kako bi se omogućio dodatni modul "mod-script-pipe" u Audacity-u, neophodno je obezbediti biblioteke ovog modula, odnosno kopirati ih u direktorijum u kome se nalazi instalacija Audacity progrmaskog alata. Početna verzija ovih biblioteka se može naći u izvornom "C" kodu na zvaničnom sajtu Audacity [5]. Za nadogradnju programskog alata Audacity dodatnim bibliotekama, odnosno modulima, korišćen je programski jezik Python. Jedan od ciljeva rada je da se kao rezultat dobije biblioteka u obliku Python modula sa metodama potrebnim za nadogradnju koja se kasnije može koristiti i za druga ispitivanja. Python je programski jezik opšte namene koji je veoma pogodan za automatizaciju i lak za učenje i razumevanje [6]. Za potrebe razvoja biblioteke za automatizaciju, korišćeni su već postojeći ispitni slučajevi koji su bili napisani u Python-u. Potrebno je napomenuti da mod-script-pipe takođe podržava Python.

III. REALIZACIJA

U okviru dodatne biblioteke, razvijeni su moduli za podešavanje alata, reprodukovanje, snimanje i analizu audio zapisa [7]. Zasebnim modulom za izvršavanje komandi je vršeno ispitivanje u okviru izvršnog računara i audio uređaja sa USB konekcijom. Na izvršnom računaru je pokretan Audacity i reprodukovani audio zapisi na audio uređajima.

A. Konfiguracija uređaja

Audio uređaji sa USB konekcijom, nad kojima su se izvršavale ispitne procedure, prikazani su u Tabeli 1**.** U tabeli su takođe prikazane različite konfiguracije uređaja:

Topology	Speed	UAC	Mode	Channel	Render SR	Render BD	Capture SR	Capture BD
Headset	High	2.0	Sync	Stereo / Mono	92 kHz	24 - bit	48 kHz	24 - bit
Headphones	Full	1.0	Sync	Stereo	44.1 kHz	16 - bit		
Microphone	Full	1.0	Sync	Stereo	48 kHz	24 - bit		

Tabela 1 – Prikaz konfiguracije za perifeje prilikom testiranja

Biblioteka za automatizaciju je verifikovana kroz primenu u postojećim sistemskim procedurama za ispitivanja audio zapisa na "Cirrus Logic CDB46L60-A1" razvojnoj ploči (audio uređaji sa USB-C konekcijom).

Platformski softver (engl. firmware) potrebno je konfigurisati kroz parametre iz Tabele 1. Ti parametri imaju sledeće značenje:

- "Topology" označava tip uređaja za testiranje (mikrofon, slušalice ili slušalice sa mikrofonom),

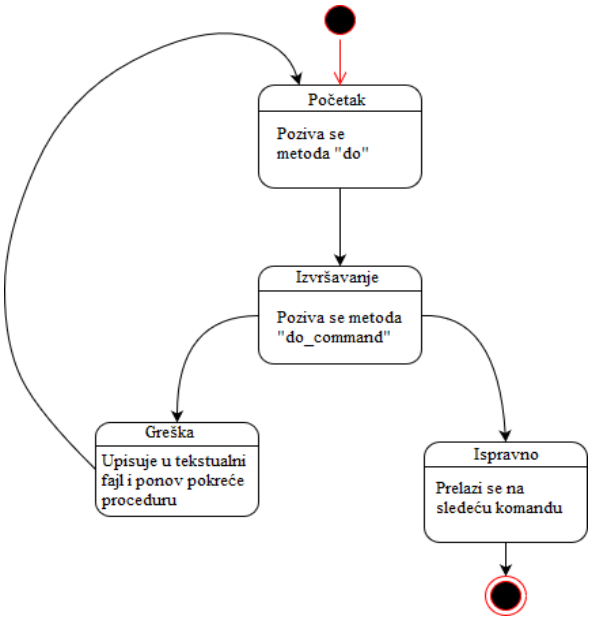
- “Speed“ označava brzinu prenosa padataka USB komunikacije,
- “UAC“ označava USB audio klasu,
- “Mode“ označava tip prenosa podataka (sinhroni ili asinhroni),
- “Channel“ označava odabir kanala (mono ili stereo),
- “Render SR“ označava učestanost odabiranja izvornog audio signala (8 kHz - 384 kHz),
- “Render BD“ označava bitsku dubinu podataka izvornog audio signala (16, 24, 32),
- “Capture SR“ označava učestanost odabiranja izlaznog audio signala,
- “Capture BD“ označava bitsku dubinu izlaznog audio signala.

Uređaj nad kojim se vrši ispitivanje, potrebno je konfigurisati za pojedinačne ispitne slučajeve i tako konfigurisan uređaj se može ispitivati na više operativnih sistema (Windows 7, Windows 10, Mac OS X, Linux).

B. Ispitivanje ispravnosti testova

Da bi se dokazala ispravnost testova, ispitivanje je vršeno na audio uređajima sa USB konekcijom, kao što su slušalice sa USB konekcijom, mikrofon sa USB konekcijom i slušalice sa mikrofonom sa USB konekcijom.

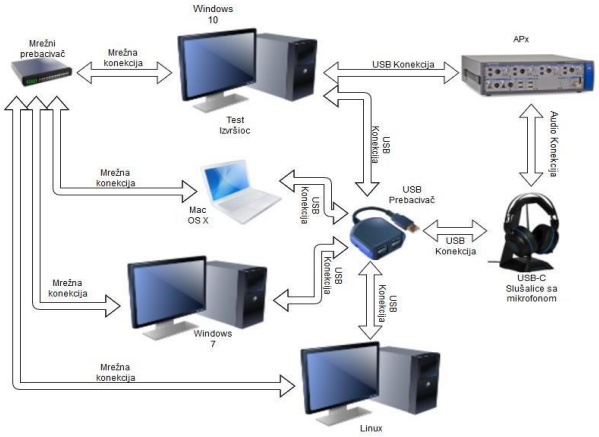
Pokretanje ispitne procedure i softverske podrške audio analizatora je realizovano slanjem naredbi (komandnih linija) u okviru “windows cmd“ konzole. Pomoću komandne linije se takođe prosleđuju parametri za pozivanje UTS-a, softverska podrška audio analizatora i parametri za određenu komandu u zavisnosti od tipa ispitnog slučaja (play, record i generate). Nakon pokrenute ispitne procedure, proverava se svaka prosleđena komanda. Na Sl. 2, se nalazi grafički prikaz procedure ispitivanja ispravnosti komande:



Sl. 2 - Grafički prikaz procedure ispitivanja ispravnosti komande

Kako se vidi na Sl. 2, ispitivanje ispravnosti komandi se zasniva na četiri stanja. Prvo stanje “Početak“ prikupi prosleđenu komandu i prelazi u sledeće stanje “Izvršavanje“. Stanje “Izvršavanja“ komandu pošalje u pomoćnu memoriju, gde se upoređuje prikupljena komanda sa nazivom komande u aplikativnom delu Audacity i vraća se povratna informacija da li je komanda ispravna ili neispravna. Iz stanja “Izvršavanja“ se prelazi u jedno od dva moguća stanja koja zavise od povratne informacije stanja “Izvršavanja“. Stanje “Greška“ neispravnu komandu upisuje u tekstualni dokument i prekida ispitnu proceduru, a korisniku se ispisuju pravila u windows konzoli kako treba da izgleda zapis komande. Stanje “Ispravno“ izvršava komandu.

Pre izvršavanja ispitnih slučajeva QA inženjer povezuje audio analizator sa izvršnim računarom i sa razvojnom pločom koja u ispitnom okruženju simulira audio uređaje sa USB konekcijom. Razvojna ploča omogućava ispitivanje ispitnih slučajeva na nivuo prosecora. Za ispitivanje na nivuo proizvoda se povezuje gotov proizvod sa audio analizatorom. Na Sl. 3 je grafički prikazano povezivanje audio uređaja sa audio analizatorom i izvršnim računarom prilikom ispitivanja na nivou audio uređaja. Ispitno okruženje je povezano preko mrežne konekcije sa izvršnim računarom i ovakva konfiguracija omugućava da se ispitivanje izvršava sa više različitih računara koji ne moraju biti fizički na istoj lokaciji i mogu da imaju različite operativne sisteme:



Sl. 3 – Grafički prikaz ispitnog okruženja za ispitivanje na nivou proizvoda

Kako se vidi na Sl. 3, ispitivanje na nivou proizvoda sa audio analizatorom je moguće izvršavati na više operativnih sistema. Komunikacija sa ostalim operativnim sistemima se odvija putem mrežne komunikacije. Audio analizator se povezuje sa izvršnim računarom i sa ispitnim proizvodom (slušalice sa mikrofonom sa USB konekcijom) putem USB komunikacije.

Nakon uspešnog povezivanja, pomoću komandnih linija se pokreće softverska podrška audio analizatora i UTS-a, unutar kog se poziva biblioteka za automatizaciju komandi u programskom alatu Audacity. U zavisnosti od potrebe ispitivanja, QA inženjer povezuje i dodatnu periferiju, u ovom slučaju USB slušalice sa mikrofonom, USB slušalice ili samo USB mikrofon.

Ispitni slučajevi koje QA inženjer treba da izvrši se mogu podeliti u tri grupe a to su:

- ispitni slučajevi sa USB slušalicama,
- ispitni slučajevi sa USB mikrofonom,
- ispitni slučajevi sa USB slušalicama i mikrofonom.

Za prva dva slučaja sa strane QA inženjera pokretanje ispitnih slučajeva se vrši direktno pomoću komandne linije koristeći samo aplikativni deo razvijene biblioteke. Za ove grupe ispitnih slučajeva QA inženjer bira između samo snimanja ili samo reprodukovanja. Inicijalno QA inženjer treba da proveri ispravnost ispitnog okruženja, tako što pokreće grupu ispitnih slučajeva namenjenih za validaciju ispitnog okruženja. Nakon dobijenog rezultata QA inženjer treba da podnese izveštaj da li je ispitni slučaj uspešan, neuspešan ili nedefinisan.

Za treću grupu ispitnih slučajeva, kod ovog načina ispitivanja potrebno je omogućiti u programskom alatu Audacity opciju da istovremeno može snimati i reprodukovati audio zapis. U ovoj grupi ispitivanja audio analizator generiše audio zapis, pošalje izvršnom računaru gde se čuva audio zapis i zatim vrati do audio analizatora koji reprodukuje audio zapis.

Ukoliko se desi da je ispitni slučaj neuspešan, potrebno je još jednom ili čak više puta pokrenuti problematičan slučaj. Ukoliko se i dalje dobija da je slučaj neuspešan, QA inženjer ima mogućnost da sam unapredi problematičan slučaj. Ako se i sa tim promenama dobija nesupešan rezultat, obaveštava se inženjer koji razvija platformski softver (engl. firmware). Kod ispitnih slučajeva sa nedifinisanim rezultatima ista je procedura provere kao za neuspešne ispitne slučajeve.

Nakon završene procedure ispitivanja, softverska podrška audio analizatora pravi word dokument u kom upisuje podatak o nazivu ispitnog slučaja i dodaje sliku sa karakteristikom u frekvetnom domenu za taj slučaj. Završetkom ispitne procedure UTS automatski prebacuje word dokument u html dokument. Nakon završenih svih ispitnih slučajeva poziva se zaseban manji program za isčitavanje podataka iz html dokumenta i upisivanje tih podataka u poseban excel dokument koji QA inženjer može da koristi za proveru rezultata. Softverska podrška audio analizatora prilikom ispitne procedure ubacuje granice za svaki ispitni slučaj.

Greške koje mogu prouzrokovati neuspešnost ispitnih slučajeva mogu biti:

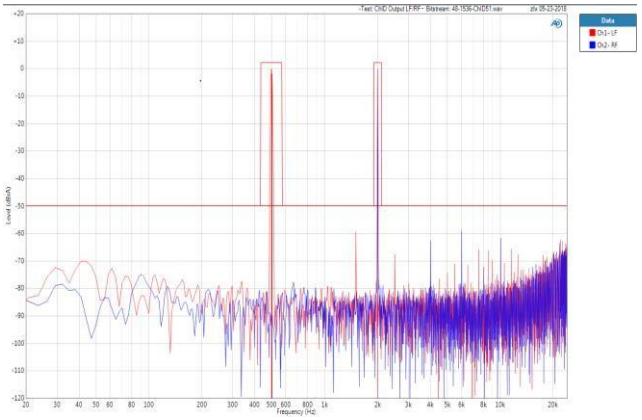
- ne reagovanje razvojne ploče na zadani takt (ovo se uglavnom dešava prilikom zadavanja više opcija)
- ili pogrešno rukovanje softverskim alatima.

Kao jedan način sigurnosti implementirano je da se izvršavanje UTS-a i alata Audacity odvija u pozadini, dok se kroz softversku podršku audio analizatora prikazuje ispravnost ispitnih slučajeva. Poželjno je prilikom ovakvih ispitivanja imati zaseban izvršni računar sa neophodnom hardverskom opremom (razvojnim pločama i mernim uređajima), kao i dodatnim periferijama.

C. Rezultati ispitivanja

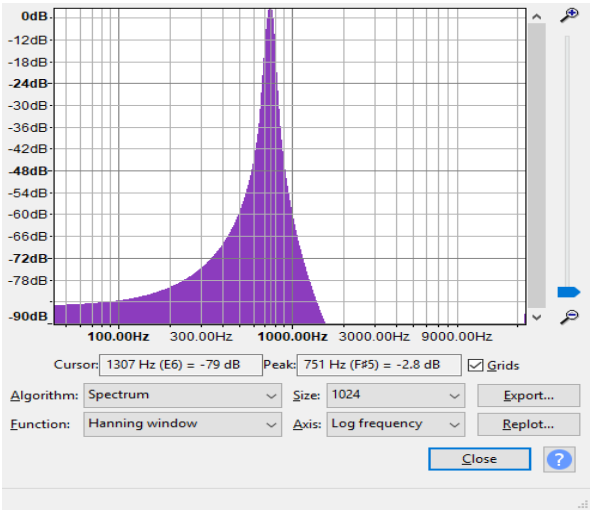
Automatizacijom samog ispitnog okruženja i integracijom programskog alata Audacity u UTS-u dobija se značajna ušteda vremena ispitivanja. Nakon upoređivanja ispitivanja pre i nakon automatizacije, dobija se veoma značajna ušteda od čak 40% prilikom celokupne ispitne procedure.

Na Sl. 4 i Sl. 5 je prikazan rezultat uspešno izvršenog ispitnog slučaja u okviru softverske podrške audio analizatora i programskog alata Audacity u obliku prenosne karakteristike u frekvetnom domenu:



Sl. 4 – Prikaz rezultata uspešno izvršenog ispitnog slučaja u okviru softverske podrške audio analizatora u frekventnom domenu

Kako se vidi na Sl. 4, u okviru softverske podrške audio analizatora su postavljene granice za ispitni slučaj. Ove granice olakšavaju vizuelnu proveru rezultata ispitnog slučaja. Ovaj rezultat se odnosni na ispitni slučaj gde se kao ispitni signal koristi dvokanalni audio zapis.



Sl. 5 – Prikaz uspečno izvršenog ispitnog slučaja u okviru programskom alatu Audacity u frekventnom domenu

Na Sl. 55 se vidi rezultat uspešno izvršenog ispitnog slučajeva koji kao ispitni signal koristi jednokanalni audio zapis.

Za potrebe ispitivanja na samom proizvodu, audio uređaji sa USB konekcijom, ispitivani su po 20 ispitnih slučajeva za svaku od ispitinih grupa. Ispitni slučajevi su verifikovani sa rezultatom uspešnog ispitivanja.

IV. ZAKLJUČAK

U okviru ovog rada implementirana je integracija programskog alata Audacity unutar UTS-a (Unified Test Setup) i Audio Precision ispitnog okruženja. Komande za programski alat Audacity su realizovane u okviru biblioteke koja može da se koristi i u ostalim ispitnim procedurama. Opisan je postupak povezivanja audio uređaja i verifikacija. Automatizovana celokupna ispitna procedura koja olakšava način ispitivanja na nivou procesora i na nivou gotovog proizvoda. Za potrebe verifikacije i ispitnih slučajeva, uspešno je implementirana integracija Audacity unutar UTS-a i Audio Precision ispitnog okruženja.

Mogućnosti za dalja istraživanja i poboljšanja mogu biti u pravcu proširenja aplikativnog dela za specifične ispitne procedure, automatizovanog grafičkog upoređivanja ostvarenih rezultata i omogućavanje ispitivanja ispitnih slučajeva na drugim mernim uređajima, što dovodi do jeftinijih hardverskih jedinica.

ZAHVALNICA

Ovaj rad je delimično finansiran od strane Ministarstva za nauku i tehnologiju Republike Srbije, na projektu tehnološkog razvoja broj: TR32029.

ABSTRACT

This paper presents one of the ways to improve the test environment for testing devices intended for decoding, processing and reproducing Audio content using the Audacity software tool. These tests are performed in two phases, at the processor level and at the product level. The test environment usually uses the APx (Audio Precision) measuring device. The improvement actually represents the integration of the Audacity program tool in these environments. Also, for the purposes of additional automation of test cases, automatic execution of commands for reproducing, recording, generating and analyzing audio records was performed.
The result of this enhancement is to reduce the error during testing and analysis, caused by the "human factor" as well as reducing the time needed to complete the entire procedure.

Implementation of the software user interface for sound recording and editing tool

Povezivanje Android Media API-ja za DASH izvore podataka

Nikola Ječmenica, Marija Jovanović, Dušan Zivkov, Đorđe Glišić

***Apstrakt*— U ovom radu je predstavljena realizacija aplikacije koja ima za cilj da reprodukuje multimedijalni sadržaj koristeći Android API niskog nivoa, pre svega MediaCodec i MediaExtractor. Ona takođe predstavlja teset aplikaciju za MediaExtractor koji kao izvor podataka koristi MediaDataSource interfejs. Aplikacija je pisana u Java programskom jeziku i predstavlja simulaciju DASH protokola prilagođenu Android TV platformi. Aplikacija ima jednostavan GUI (Graphical User Interface).**

***Ključne reči*—MediaCodec, MediaExtractor, AudioTrack, MPEG-DASH, MPD, Android**

I. UVOD

Zahvaljujući velikom broju raznovrsnih API-ja (Application programming interface), developerima je dosta olakšan rad i omogućeno stvaranje projekata bilo kog tipa.

Trenutno najviše korišćen operativni sistem za pametne telefone je Android OS, koji je svoju primenu pronašao i u drugim uređajima kao što su televizori, kamere, igračke itd.[1].Druga po redu najrasprostranjenija upotreba mu je kao operativni sistem pametnih televizora koji postaju sve zastupljeniji. Još uvek nije napisan dovoljan broj aplikacija koje bi se na njima pokretale i nemamo toliki spektar mogućnosti kao što je to slučaj sa mobilnim uređajima. Najpopularnije i najviše korišćene su one za reprodukciju multimedijskih sadžaja.

MPEG-DASH je jedan od protokola za reprodukciju multimedijalnog sadržaja preko interneta. Omogućava visokokvalitetan protok multimedijalnog sadržaja koji se isporučuje preko HTTP servera[9]. Smanjeno kašnjenje prilikom pokretanja, izbegava baferovanje, prilagođavanje situaciji klijentskog propusnog opsega su neke od prednosti u odnosu na starije tehnike kao što su HLS(HTTP Live Streaming)[2].

Jedna od najvećih produkcijskih kuća Netflix, i jedne od najvećih kompanija kao kao što je Google nedavno su prešle na DASH standard, što je znatno doprinelo ovom procentu

Aplikcaija ima za cilj i testiranje MediaExtractor-a, kome smo kao izvor podataka stavili MediaDataSource interfejs. Njega smo impelmentirali tako da čita DASH komponente iz lokalnog direktorijuma, u tom smislu se radi o simulaciji DASH protokola.

U poglavlju II biće detaljan opis Android Medija API-ja nižeg nivoa koji su ključni za implementaciju ove aplikacije.

U poglavlju III biće opisan MPEG-DASH protokol. Biće prikazan način rada, prednosti u odnosu na starije protokole.

U poglavlju IV biće data implementacija aplikacije, način simulacije DASH protokola[6], kao i način korišćenja aplikacije.

Rad je završen poglavljem V u kome su izvedeni zaključci uz predloge daljeg unapređenja aplikacije.

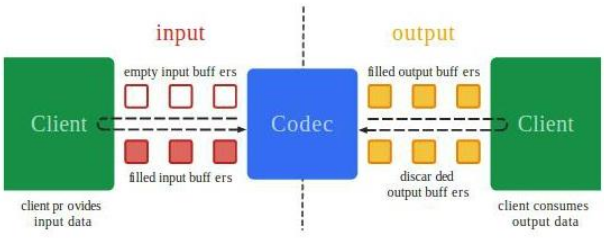
II. ANDROID MEDIJA API

Što se tiče Android medija API-ja višeg nivoa tu je MediaPlayer koji se koristi za ubacivanje video snimaka u aplikaciju. Ovaj API je veoma jednostavan za korišćenje. Jednostavnost korišćenja ovog API-ja ima svoje mane. Naime, ako neko ima potrebu da doda neke funkcionalnosti koje su potrebne za određenu aplikaciju nije u mogućnosti to da uradi. Ova ograničenja su prevaziđena dodavanjem API-ja nižeg nivoa MediaCodec, MediaExtractor, AudioTrack itd.

MediaCodec se koristi za dekodovanje kompresovanih audio i video formata i kodovanje u RAW format[4].



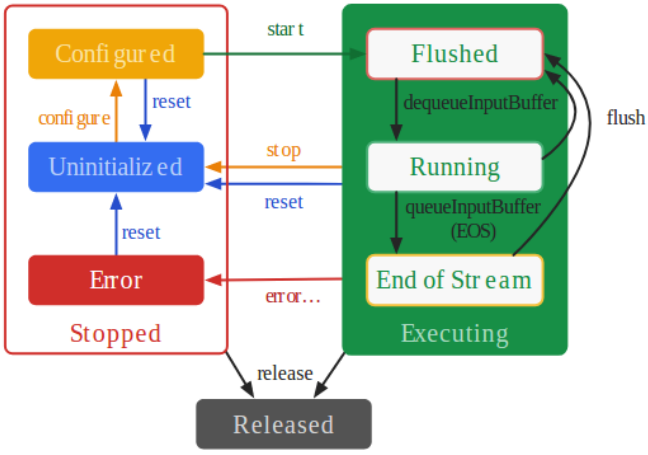
Slika1. Ilustracija rada MediaCodec-a

MediaCodec dobija ulazne podatke, nad njima radi obradu i daje izlazne podatke. Prenos podataka se vrši pomoću ulaznih i izlaznih bafera, pri čemu se obrada nad podacima vrši asinhrono. Prvo klijent zatraži prazan ulazni bafer, napuni ga podacima, zatim pošalje kodeku. Kodek obradi dobijene podatke, a zatim napuni prazan izlazni bafer. Na kraju klijent dobije napunjen bafer, iskoristi podatke zatim ga vrati nazad kodeku. Sve ove operacije se izvršavaju u paraleli. Na slici 1. prikazana je ilustracija rada MediaCodec-a.

Tokom rada MediaCodec se nalazi u jednom od tri stanja: Stopped, Executing i Released. Stopped je stanje u kom je MediaCodec zaustavljen i sastoji se od tri podstanja: Uninitialized, Configured i Error. Executinig je stanje izvršavanja i naizmenično prolazi kroz tri podstanja: Flushed, Running, End-of-stream[4].

Kada se napravi instanca klase MediaCodec ona se nalazi u stanju Stopped, podstanje Uninitialized. Sledeća korak je konfiguracija koja se radi pomoću odgovarajuće metode i zatim MediaCodec prelazi u podstanje Configured. Odavde se, odgovarajućom metodom, prelazi u Executing stanje, Flushed podstanje. Nakon ovog, dobija indeks praznog ulaznog bafera, po završetku punjenja ovog bafera prelazi u Running podstanje. U ovom podstanju MediaCodec više ne prihvata ulazne bafere već samo generiše izlazne. Pomoću odgovarajuće metode u svakom trenutku dok je MediaCodec u Executing stanju moze da se vrati u Flushed podstanje.

Kada se završi sa korišćenjem, neophodno ga je osloboditi čime prelazi u Released stanje. Prelazna stanja su prikazana su na slici 2.



Slika2. Prelazna stanja

MediaExtractor olakšava vađenje podataka koji prosli kroz demukser, uglavnom kodiranih, multimedijalnih podataka iz izvora podataka. Prvo se pravi nova instanca MediaExtractor-a, zatim se postavljaju podaci koji treba da se kodiraju[5]. Prolazi se kroz sve trake u jednoj petlji, i uzimaju se trake odgovarajućeg formata. Postoji metoda pomoću koje se dobija format trake i na osnovu toga se odlučuje da li će traka biti obrađena ili preskočena.

Pretpostavimo da je MediaCodec spreman da primi podatke odnosno da mu je bafer podešen, odgovarajućom metodom dekodovani uzorak iz MediaExtractor-a stavljamo u ulazni bafer počevši od zadatog pomeraja. Kada je završeno sa korišćenjem potrebno je osloboditi resurse[5].

AudioTrack kontroliše i pušta audio resurse za Java aplikaciju. Može da radi u dva režima, statički ili striming.

U režimu strimovanja pomoću blokirajuće funkcije upisuju se tokovi podataka u AudioTrack. Ovaj režim je koristan kada želimo da pustimo audio podatke koji su preveliki da stanu u memoriju. Statički režim je pogodan kada su podaci kratki zvukovi koji staju u memoriju[5].

Po kreiranju objekta AudioTrack-a radi se inicijalizacija njegovih bafera. Veličina ovih bafera određuje koliko dugo će AudioTrack moći da pušta pre nego što ostane bez podataka.

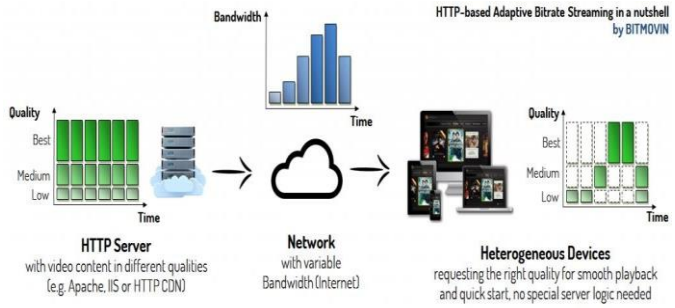
III. MPEG-DASH

MPEG-DASH (Dynamic Adaptive Streaming over HTTP) predstavlja adaptivnu tehniku striminga bitova koja omogućava visokokvalitetan protok multimedijalnog sadržaja preko interneta koji se isporučuje sa HTTP server[8].

MPEG-DASH je dostupan na Android platform pomoću ExoPlayer-a. YouTube i Netflix takođe koriste ovaj protokol.

Za razliku od HLS, HDS i Smooth Streaming-a, DASH je kodek agnostik, što znači da može da koristi sadržaj koji je kodiran bilo kojim formatom kodiranja, kao što su H.265, H.264, VP9 itd[7].

Osnovna ideja ovog protokola je sledeća – sadržaj razdvaja u niz malih segmenata. Segmenti su obezbeđeni na veb serveru i mogu se preuzeti preko HTTP protokola koji su u skladu sa GET zahtevima, kao što je prikazano na slici 3., gde HTTP služi tri različita kvaliteta niski, srednji i visoki iseckana u segmente jednake dužine[9].



Slika3. Način rada MPEG-DASH-a

Klijent automatski bira segment sa najvećom rezolucijom koja se može preuzeti u vremenu za reprodukciju bez izazivanja smetnji i ponovnog učitavanja sadržaja. Stoga se MPEG-DASH klijent može neprimetno prilagoditi promenama mrežnih uslova i obezbediti visokokvalitetnu reprodukciju bez kočenja i ponovnog baferovanja.

Da bi opisali vremenske i strukturne odnose između segmenata MPEG-DASH uvodi MPD (Media Presentation Description) strukturu. MPD je XML datoteka koja predstavlja različite kvalitete multimedijalnog sadržaja i pojedinačnih segmenata svakog kvaliteta. Ova struktura obezbeđuje vezivanje segmenata na rezoluciju, početno vreme trajanja, trajanje segmenata[2].

MPD je hjerarhijski model podataka. Svaki MPD može da sadrži jedan ili više perioda. Svaki od tih perioda sadrži medijske komponente kao što su video komponente npr. različiti uglovi gledanja, audio komponente sa različitim jezicima itd. Ove komponente imaju određene karakteristike kao što su bitrate, framerate, audio kanali itd., koje se ne menjaju tokom jednog perioda[7].

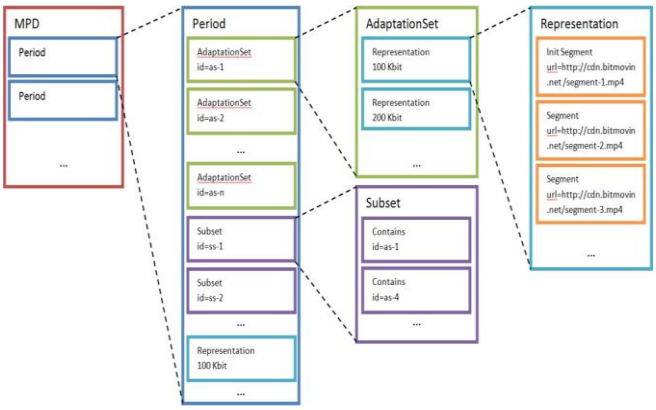
Tipične medijske komponente kao što su video, audio ili

titlovi organizovani su u adaptacioni set. Svaki period sadrži jedan ili više adaptacionih setova koji omogućavaju grupisanje različitih multimedjialnih komponenti koji su logički povezane. Na primer komponente sa istim kodekom, jezikom, rezolucijom, formatom audio kanala itd. mogu biti u istom adaptacionom setu. Ovaj mehanizam omogućuje korisniku da eliminiše niz multimedijalnih komponenti koje ne ispunjavaju određene zahteve.

Adaptacioni set se sastoji od skupa reprezentacija koje sadrže izmenjive verzije odgovarajućeg sadržaja. Iako jedna reprezentacija omogućava strimovanje u jednoj rezoluciji, više reprezentacija omogućava korisniku prilagođavanje medija na trenutne uslove mreže.

Reprezentacija je podeljena u segmente koji omogućavaju prebacivanje između pojedinačnih reprezentacija tokom reprodukcije. Ovi segmenti su opisani URL-om, a u određenim slučajevima dodatnim opsegom bajtova ako su segmenti stavljeni u veće datoteke. Segmenti u reprezentacijama obično imaju istu dužinu u vremenu i uređuju se po vremenskoj liniji što omogućava glatko prebacivanje reprezentacija tokom reprodukcije. Za razliku od drugih sistema, MPEG-DASH ne ograničava dužinu trajanja segmenta ili daje savete o optimalnoj dužini. Ovo se može izabrati od datog scenarija, duzi segmenti omogućavaju bolju kompresiju, a kraći segmenti se koriste za uslove velike promenljive propusnosti kao što su mobilne mreže, jer omogućavaju brže i efikasnije prebacivanje između pojedinačnih bitova.

Segmenti se dalje mogu podeliti na manje podsegmente koji predstavljaju skup manjih pristupnih jedinica u datom segmentu. Na slici 4. prikazana je MPD struktura.



Slika4. Struktura MPD-a

Tokom reprodukcije sadržaja, proizvoljno prebacivanje između reprezentacija nije moguće u bilo kojoj tački u toku i potrebno je razmotriti određena ograničenja. Dakle segmenti se ne smeju preklapati, takodje nisu dozvoljene zavisnosti izmedju segmenata. Da bi omogućio prebacivanje između reprezentacija, MPEG-DASH je predstavio SAP (Stream Access Point) na kojima je to moguće.

IV. REALIZACIJA APLIKACIJE

Aplikacija je u potpunosti napisana u Java programskom jeziku. Isključivo se oslanja na Android medija API niskog nivoa. Aplikacija treba da obezbedi gladak prelaz sa jedne rezolucije na drugu u toku reprodukcije.

Nakon pokretanja aplikacije korisniku se prikazuje ekran sa četiri dugmeta, gde može da izabere da li želi običan strim u jednoj rezoluciji, da li želi promenu dve različite rezolucije, promenu tri različite rezolucije. Na četvrto dugme bira video koji želi da reprodukuje. Na slici 5. prikazan je ekran aplikacije nakon pokretanja.

Slika5. Početni ekran aplikacije

Postavljanje izvora podataka za MediaExtractor vrši funkcija *setDataSource*, koja kao argument prima fajl deskriptor ili putanju do odgovarajućeg fajla koji predstavlja izvor podataka.

Kako ovo treba da bude simulacija DASH-a, nećemo koristiti nijedan od navedenih argumenata već ćemo implementirati posebnu klasu za to. Ovde koristimo video fajlove koji predstavljaju kratke segmente jednog videa. Uvek se počinje sa inicijalnim segmentom, koji ne sadrži video ili audio za reprodukciju, već informacije potrebne za reprodukciju tih segmenata kao celine.

Za ovo smo implementirali apstraktnu klasu *MediaDataSource* koja se upravo koristi kada aplikacija ima posebne zahteve za dobijanje medija podataka. Metode ovog intefejsa se pozivaju iz različitih niti. Sinhronizacija već postoji između poziva metoda.

Funkcija *setDataSource* prima *MediaDataSource* kao argument, na taj način postavljamo izvor podataka za ovu aplikaciju.

Prvo pročitamo inicijalni segment i sačuvam ga kao jedan bajt. Zatim u petlji čitamo sledeće segmente u zavisnosti koliko ih ima i smeštamo u bafer bajtova. Funkcijom *System.arraycopy* spajamo inicijalni segment i ostale segmente u jedan bafer i time hranimo MediaExtractor.

Svi segmenti koji su potrebni aplikaciji nalaze se na Android uređaju, u direktorijumu /Movies/. Fajl, za čiji konstruktor treba putanja do odgovarajućeg segmenta, prosledimo funkciji *readAllBytes* koja vraća bajtove.

Za audio je potpuno ista implementacija samo se stavi putanja do audio segmenata.

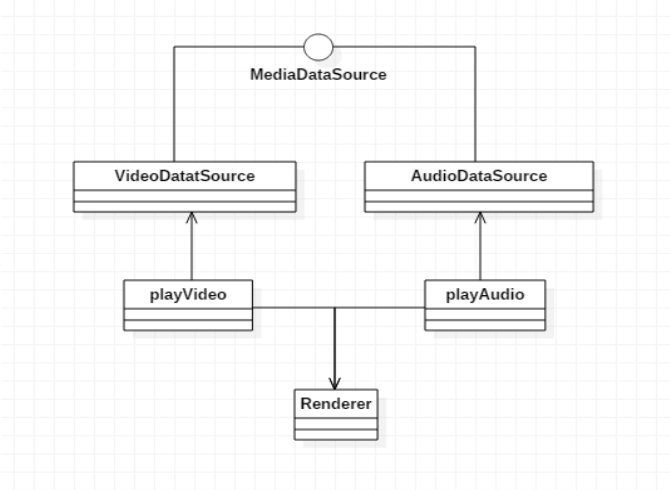
Kako je potrebno reprodukovati audio i video, moramo da koristim dva MediaCodec-a. Jedan za dekodovanje videa, drugi za dekodovanje audia. Po istoj logici je potrebno koristiti i dva MediaExtractor-a.

Na slici 6. prikazan je UML dijagram klasa koje su korišćene.

Kako nakon promene rezolucije potrebno je krenuti ponovo od inicijalnog segmenta za novu rezoluciju, na primer

reprodukuje se: init1, seg1, seg2, seg3 i od trećeg segmenta kreće nova rezolucija, tada je potrebno reprodukovati init2, seg4, seg5, seg6, itd.

Ovde je nastao problem, jer kad sa dva različita init-a hranimo MediaExtractor dolazi do greške.. Zbog ovoga je potrebno da koristimo novi MediaExtractor, odnosno potrebno je da koristimo onoliko MediaExtractor-aa koliko ima različitih rezolucija.



Slika 6. UML dijagram klasa

MediaCodec može da prima podatke od više MediaExtractor-a, samo pre prelaska na novi MediaExtractor, mora se pozvati metoda *release*..

Što se tiče same reprodukcije, prvo smo implementirali interfejs *SurfaceHolder.Callback* koji prati sve promene na površini na kojoj se vrši reprodukcija. Zatim deklarišemo *SurfaceView*, *Surface*, *SurfaceHolder*.

U funkciji *onCreate*, koja se poziva jednom na početku, funkcijom *setContentView* postavljamo odgovarajući XML fajl. Zatim prethodno deklarisani *SurfaceView* povežemo sa *SurfaceView*-om koji smo pstavili u xml fajl.

Kako je za konfiguraciju MediaCodec-a potreban *Surface*, njega dobijamo iz prethodno inicijalizovanog *SurfaceView*-a. Takođe iz *SurfaceView*-a dobijamo *SurfaceHolder*, kome prosleđeujemo implementirani *Callback*, čime prati promene na pozadini odgovarajućeg xml fajla. Na slici 6. prikazana je reprodukcija videa.

Slika6. Reprodukcija videa u aplikaciji

V. ZAKLJUČAK

Android OS TV uređaji su sve zastupljeniji na stranom i našem tržistu, a upravo aplikacije potrebne za takve uređaje su aplikacije koje rade sa multimedijalnim sadržajem. Može se zaključiti da će aplikacije koje reprodukuju multimedijalni sadržaj biti sve potrebnije u budućnosti.

Ova aplikacija je realizovana korišćenjem Java programskog jezika u AndroidStudio okruženju koje omogućava testiranje aplikacija na raznim uređajima, koji podržavaju Android OS, u vidu emulatora.

Deo aplikacije koji predstavlja MediaExtractor sa MediaDataSource iterfejsom kao izvorom podataka može se korsititi za rad sa DASH-om u uslovima kada nema mreže. Ovaj API mogu da koriste aplikacije poput ExoPlayer-a, kako bi promenili izvor podataka.

Dalji razvoj ove aplikacije može da bude opcija da korisnik može sam da bira rezoluciju u kojoj želi da reprodukuje sadržaj.

ABSTRACT

This paper presents an application that amis to reproduce media content that uses Android APIs, primarly MediaCodec and MediaExtractor. The application is written in Java programming language and represents simulation of the DASH tuning protocol for the Android TV platform. The application has a simple GUI (Graphicla User Interface).

Connecting the Android Media API to DASH data source

Generalizacija prikaza funkcija i stanja uređaja u IoT sistemima

Lana Salai, Igor Stefanović, Roman Pavlović, Ištvan Pap, Miloš Milanović

***Apstrakt*—U ovom radu opisan je koncept rešenja prikaza funkcionalnosti IP (eng. *Internet protocol)* uređaja krajnjim korisnicima sistema za kućnu automatizaciju na pojednostavljen način. Rešenje podrazumeva generički prikaz fizičkih osobina uređaja, pri čemu se informacije o uređajima dobavljaju korišćenjem WISE (eng. *WiFi Sensors*) protokola. Podelom funkcionalnosti uređaja po prioritetima, moguće je iscrtati kontrolne ekrane za funkcionalno različite uređaje na intuitivan način. To značajno olakšava održavanje i proširivanje sistema pametnih kuća novim uređajima.**

***Ključne reči*—pametna kuća; protokol; WISE; IP; uređaji; mobilna aplikacija;**

I. Uvod

Stalni razvoj tehničkih rešenja, zajedno sa konceptom uređaja povezanih na Internet, doživljava procvat na polju kućne automatizacije. Iz dana u dan raste dostupnost električnih uređaja koji nude direktno povezivanje na Internet. Međutim, koriste razne komunikacione protokole koji su uglavnom namenjeni samo za određeni tip uređaja ili za uređaje jednog proizvođača. Iz tog razloga, trenutno ne postoji jedno univerzalno rešenje programske podrške za upravljanje uređajima različitih funkcionalnosti. S obzirom da sistem pametne kuće sačinjava više različitih tipova namenskih uređaja, uloga glavne komponente ovog sistema, centralnog kontrolera, je da obezbedi uniforman pristup perifernim uređajima različitih protokola.

Namenski uređaji niske potrošnje se uglavnom oslanjaju na *ZigBee* [1], *Z-Wave* [2] i *Bluetooth Low Energy (BLE)* [3] protokol. Ovi protokoli nude mogućnost povezivanja uređaja u mrežu *mesh* topologije [4], pri čemu je komunikacija ograničena na lokalnu mrežu. Nasuprot ovim uređajima, uređaji koji se oslanjaju na IP protokol mogu biti dostupni kako u lokalnoj tako i u globalnoj mreži.

Imajući u vidu da su uređaji integrisani unutar sistema pametnih kuća ograničeni sa stanovišta računarskih resursa, protokol koji oni koriste mora da ispunjava uslove veoma ograničenog okruženja (mala memorija, niska potrošnja i procesorske mogućnosti). Kao rešenje predložen je komunikacioni protokol WISE [5], isključivo namenjen realizaciji namenskih uređaja za upotrebu u sistemima kućne automatizacije. On spaja prednosti postojećih, standardizovanih komunikacionih protokola sa prednostima IP protokola, nudeći unificiranu osnovu za realizaciju najrazličitijih uređaja.

II. IoT sistem

Sistem kućne automatizacije čini više distribuiranih komponenti među kojima je glavna komponenta centralni kontroler. On predstavlja posrednika u komunikaciji između klijentskih aplikacija i perifernih uređaja. Uloga centralnog kontrolera je da komande primljene od strane korisnika prosledi perifernim uređajima, kao i da informacije od značaja koje pristižu sa perifernih uređaja prosledi korisniku. Kako bi komunikacija sa uređajima različitog tipa bila moguća, neophodno je da centralni kontroler implementira komunikacione protokole koje koriste ti uređaji.

Zadatak klijentske aplikacije je da pruži korisniku uvid u trenutno stanje svih uređaja i da omogući udaljenu kontrolu tih uređaja. Posredstvom aplikacije, korisnik ima mogućnost da se poveže sa centralnim kontrolerom i u lokalnoj i u globalnoj mreži. U slučaju kada su klijentska aplikacija i centralni kontroler u lokalnoj mreži, komunikacija između njih je bežična i bez posrednika. Međutim, ukoliko se aplikacija nalazi izvan lokalne mreže, tada se javlja potreba za drugim načinom pristupa centralnom kontroleru. Iz tog razloga uvodi se servis u oblaku (eng. *cloud*) koji predstavlja poslužioca (eng. *server*) koji je konstantno povezan sa centralnim kontrolerom i dostupan je na globalnoj mreži.

III. WISE PROTOKOL

WISE protokol rešava problem uniformne realizacije IP uređaja različitih funkcionalnosti za upotrebu u sistemu pametnih kuća. Definiše i standardizuje uključivanje uređaja u sistem, njihovu konfiguraciju kao i model razmene poruka, odnosno pribavljanje podataka i kontrolu samih uređaja. Protokol definiše različite tipove funkcionalnosti podržanih od strane namenskih uređaja. Ukoliko uređaj podržava funkcionalnosti definisane ovim protokolom, one su prepoznate od strane centralnog kontrolera sistema. Time je omogućen pristup fizičkim osobinama uređaja, dobavljanje informacija od značaja i eventualna promena stanja od strane krajnjih korisnika sistema pametne kuće, posredstvom klijentskih aplikacija. Protokolom je definisano sledeće:

- Režimi rada:
  a) Režim u kojem se centralni kontroler nalazi u istoj mreži kao i IP uređaj. U ovom režimu uređaj pretražuje mrežu kako bi dobio potrebne informacije o centralnom kontroleru upotrebom SSDP (eng. *Simple Service Discovery Protocol*) protokola [6]. Prednosti su brzina razmene informacija i mogućnost te razmene bez pristupa Internetu
  b) Režim u kojem se centralni kontroler izvršava kao deo Internet oblaka. Uređaj se povezuje sa centralnim kontrolerom sa unapred definisanom adresom putem HTTP (eng. *Hypertext Transfer Protocol*) protokola [7]. Dobija se distribuirana mreža uređaja direktno povezanih na Internet, bez postojanja centralnog kontrolera kao fizičke komponente
- Model razmene poruka:
  Sisteme pametnih kuća karakteriše potreba za asinhronom komunikacijom i velikom propusnom moći. Takođe je od velikog značaja odnos zaglavlja i sadržaja poruke koja se razmenjuje među komponentama, pogotovo kod poruka kratkog sadržaja. Kako bi protokol ispunio ove veoma stroge zahteve, kao osnova za njegovu implementaciju prihvaćen je javno dostupan protokol aplikativnog sloja ISO/OSI steka [4] – MQTT (eng. *Message Queuing Telemetry Transport*) protokol [8]. On predstavlja jedan od najzastupljenijih protokola unutar IoT (eng. *Internet of Things*) zbog svoje jednostavnosti, asinhronosti, kompatibilnosti i fleksibilnosti. Baziran je na principu pretplate i objave na određene teme od značaja, pri čemu je posrednik u komunikaciji komponenta nazvana broker.
  WISE protokol definiše formate tema i četiri tipa poruka [9] koje učestvuju u razmeni:
  1. Zahtev
  2. Odgovor
  3. Obaveštenje
  4. Status
- Priključivanje uređaja na Internet i priključivanje uređaja internoj mreži centralnog kontrolera
- Upravljanje i održavanje mreže:
  Uvode se pojmovi „spavajućih“ i „aktivnih“ uređaja, pri čemu prvi tip predstavlja uređaje koji objavljuju svoja stanja centralnom kontroleru, pri čemu kontroler ta stanja može da promeni samo u trenutku kada se spavajući uređaji „probude“. Ovi uređaji nemaju konstantno uspostavljenu vezu sa kontrolerom. Drugi tip predstavlja uređaje koje je moguće kontrolisati u svakom momentu zbog toga što je njihova veza sa kontrolerom konstantna (ukoliko se ne uzme u obzir da usled drugih uticaja može doći do prekida veze). Protokolom su definisana ponašanja uređaja, u pogledu održavanja mreže, u oba slučaja.
- Podržane funkcionalnosti IP uređaja:
  Funkcionalnost IP uređaja (protokolom definisana kao „*Service*“) predstavlja skup više povezanih fizičkih osobina uređaja (definisanih kao „*Property*“). Povezujemo ih u grupe, čime se odvajaju različiti skupovi funkcionalnosti. Ti skupovi su protokolom definisani kao „*Group*“, što sve zajedno čini pojam uređaja.

FUNKCIONALNOSTI UREĐAJA PODRŽANE WISE PROTOKOLOM

Device	Informacije o uređaju
Battery	Informacije o bateriji uređaja
Switch	Sprega ka promeni stanja uređaja
Light	Sprega ka promeni stanja svetla na uređaju
Temperature	Informacija o temperaturi koju je izmerio uređaj
LevelControl	Sprega ka promeni nivoa fizičke osobine uređaja
Dim	Sprega ka promeni nivoa osvetljenja
Color	Sprega ka promeni boja svetla uređaja
ColorTemperature	Sprega ka promeni temperature boje svetla
Alarm	Informacija o stanjima uređaja čije se promene mogu objaviti
Humidity	Informacija o trenutnoj vlažnosti vazduha koju je izmerio uređaj
Gas	Informacija o tome da li je uređaj detektovao neki od potencijalno opasnih gasova
PowerMetering	Informacija o potrošnji energije, itd.
Shutter	Sprega ka podešavanju roletni na prozoru

Thermostat	Sprega ka podešavanju termostata
Diagnostic	Osnovne informacije o dijagnostici uređaja
MotionDetection	Informacija o tome da li je uređaj detektovao pokret u svojoj blizini
Contact	Informacija o tome da li ima kontakta na magnetu uređaja
Flood	Informacija o tome da li je uređaj detektovao poplavu
Smoke	Informacija o tome da li je uređaj detektovao dim

IV. PRIKAZ UREĐAJA I MOGUĆNOSTI

Ideja rada je da se na generički način korisniku prikaže bilo koji IP uređaj dodat u sistem, što je predstavljeno na primeru korišćenja WISE protokola i njegovih funkcionalnosti. Njime je moguće prikazati nebrojeno mnogo IP uređaja koji implementiraju ovaj protokol, a broj funkcionalnosti je lako proširiv ukoliko nastane potreba za opisom novih fizičkih osobina uređaja.

Centralni kontroler, kao posrednik u komunikaciji klijentske aplikacije i krajnjeg uređaja služi da apstrahuje obe strane komunikacije. Na strani kontroler-uređaj, on dobavlja skupove funkcionalnosti IP uređaja i mapira ih na interno definisane funkcionalnosti. Sa druge strane, na korisničkoj aplikaciji moguće je dobaviti sve funkcionalnosti uređaja, kako bi bile prikazane krajnjem korisniku, posredstvom drugog protokola komunikacije, implementiranog i na strani aplikacije i na strani centralnog kontrolera.

U slučaju da je IP uređaj već poznat centralnom kontroleru, odnosno kontroler prepoznaje njegov model i implementira čitav skup servisa koje uređaj poseduje, iscrtavanje informacija o uređaju na krajnjim aplikacijama vrši se statički, koristeći unapred poznate izglede kontrolnih ekrana specifične za svaki od uređaja. Na strani aplikacije, za svaki servis, unapred je određen izgled komponente koja se prikazuje.

Međutim, u slučaju da centralni kontroler ne prepoznaje uređaj po njegovom imenu, modelu i ostalim karakterističnim fizičkim osobinama, on od uređaja zahteva sve potrebne informacije slanjem komandi definisanih WISE protokolom. Tako dobija skup funkcionalnosti koje prenosi do krajnje aplikacije. U samoj aplikaciji, moguće je iscrtati kontrolni ekran na osnovu dobijenih funkcionalnosti. Samo generičko prikazivanje se fokusira na to da su funkcionalnosti grupisane po prioritetima kako kontrolni ekrani ne bi bili pretrpani nekim, korisniku irelevantnim podacima sa uređaja.

Postojeća ideja podele funkcionalnosti po prioritetima se bazira na tome da u prvu grupu prioriteta spadaju sve senzorske funkcionalnosti koje korisniku pružaju informaciju o trenutnom stanju koje IP uređaj očitava, naravno ukoliko su iste podržane na uređaju.

Ukoliko ne postoji ovaj tip funkcionalnosti, proverava se druga prioritetna grupa koju čine jednostavne kontrolne funkcionalnosti kao što su *Switch*, *Dim*, itd.

U treću grupu funkcionalnosti spadaju komplikovanije funkcionalnosti koje sadrže veći skup fizičkih osobina IP uređaja, pa je samim tim i kontrolni ekran za njih složeniji i zahteva više mesta za prikaz.

Kontrolni ekrani služe da prikažu korisniku najznačajnije informacije, kao što su očitana stanja sa senzora, odnosno komponente za kontrolisanje uređaja. Oni se prvi prikazuju korisniku pri dodavanju uređaja u sistem.

V. TESTIRANJE I REALIZACIJA

U okviru postojećeg sistema kućne automatizacije izvršeno je testiranje inicijalne implementacije predložene ideje. Mobilna aplikacija u kojoj su prikazani kontrolni ekrani IP uređaja pisana je za iOS platformu u *Objective-C* programskom jeziku.

Platforma na kojoj se izvršava softver centralnog kontrolera naziva se DOC400 (*Desktop OBLO Controller 400*) [10]. Bazirana je na Qualcomm WD114 sistemu na čipu [11] sa 64MB RAM memorije.

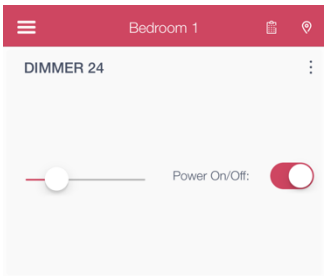
Centralni kontroler šalje informacije klijentskim aplikacijama u JSON (eng. *JavaScript Object Notation*) [12] formatu. Svaka funkcionalnost je struktuirana po određenom standardu. Može sadržati jednu ili više fizičkih osobina od kojih svaka poseduje svoje atribute. Ti atributi su ključni za tačno određen prikaz te fizičke osobine. Atributi sadrže skup vrednosti koje fizička osobina može imati, kao i trenutno podešenu odnosno očitanu vrednost iz tog skupa.

S druge strane, klijentske aplikacije imaju predefinisane klase koje se koriste kako bi se svaka funkcionalnost predstavila na korisničkom interfejsu. Polja tih klasa su tačno predviđena za parsiranje vrednosti iz JSON objekta u primitivne tipove podataka koji se zatim čuvaju u instancama tih klasa. U zavisnosti od tipa funkcionalnosti, iste fizičke osobine se mogu različito mapirati. Na primer, za *MotionDetection* funkcionalnost, koja ima fizičku osobinu *stanje* (skup vrednosti: *true/false*), vrednosti se mapiraju na DA/NE, dok se za *Contact* funkcionalnost, čiji je skup vrednosti isti, vrednosti mapiraju na OTVORENO/ZATVORENO. Za senzorske funkcionalnosti, dodatno se definišu vizuelne komponente koje jasno prikazuju njihovu namenu. Uređaji koji zahtevaju interakciju sa korisnikom sadrže funkcionalnosti kojima je moguće upravljati i one su grafički predstavljene pomoću komponenti kao što su prekidačke (eng. *switch*), odnosno klizne (eng. *slider*) kontrole.

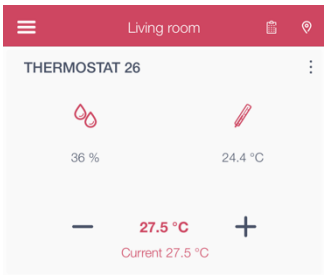
U aplikaciji je definisana klasa koja predstavlja generički uređaj i ona sadrži skup svih funkcionalnosti koje WISE protokol podržava. One su raspoređene po prioritetu i određen je maksimalan broj funkcionalnosti koje je moguće prikazati na jednom kontrolnom ekranu. Nakon što se lista funkcionalnosti dobavi od strane centralnog kontrolera, prolazi se kroz listu podržanih WISE funkcionalnosti i ukoliko se funkcionalnost nalazi u listi dobijenih funkcionalnosti, ona se iscrtava na ekranu.

Uzimajući u obzir da trenutno ne postoje fizički uređaji koji implementiraju WISE protokol, testiranje je obavljeno na simuliranim WISE uređajima koristeći *JMeter* alat [13]. S obzirom da su uređaji virtuelni, njihovi servisi ne sadrže realne karakteristike i služe samo za prikaz informacija korisniku.

Sl. 2. Kontrolni ekran za senzorske funkcionalnosti



Sl. 3. Kontrolni ekran za jednostavniji tip funkcionalnosti



Sl. 4. Kontrolni ekran koji predstavlja i komplikovan tip funkcionalnosti (Postavljanje temperature na termostatu)

Namena *JMeter* alata je simulacija klijenata različitih protokola, što su ovom slučaju IP uređaji. Alat podržava različite protokole i pisan je u Java programskom jeziku.

S obzirom da se oslanja na paralelno izvršavanje, pri čemu svaka nit predstavlja jednog klijenta, iskorišćen je u situaciji gde je jedan klijent zapravo jedan IP uređaj. Svaki od IP uređaja prolazi proces priključivanja internoj mreži centralnog kontrolera. Nakon uspešnog povezivanja, za svaki uređaj simuliran je prijem komandi za dobavljanje informacija o uređaju gde se između ostalog dobija i lista funkcionalnosti koje uređaj podržava.

Od 30 pokrenutih virtuelnih IP uređaja, svih 30 su uspešno prošli proces priključivanja. Prosečno vreme za odgovor na zahtev dobavljanja informacija o uređaju (od strane centralnog kontrolera ka uređaju) je 52ms. Najkraće vreme je 13ms, a najduže vreme izvršavanja 915ms.

Od strane aplikacije je takođe poslat zahtev ka centralnom kontroleru za dobavljanje informacija o uređaju. U odgovoru tog zahteva nalazi se lista funkcionalnosti uređaja. Prolaskom kroz listu, ispitani su prioriteti i funkcionalnosti su povezane sa odgovarajućom grafičkom komponentom koja ih predstavlja.

VI. Zaključak

Protokolom, prikazanim u ovom radu, definisan je proces uparivanja IP uređaja sa centralnim kontrolerom pametne kuće, bez obzira na njegovu lokaciju, kao i ponašanje uređaja i centralnog kontrolera. U internoj mreži centralnom kontroleru je omogućena potpuna interakcija sa IP uređajem kroz protokolom definisanu spregu. S obzirom da uređaji mogu imati različite funkcionalnosti, protokolom je pokriven dovoljan broj funkcionalnosti kako bi se interakcija sa uređajima olakšala, a samim tim i kako bi se nebrojeno mnogo različitih uređaja moglo povezati sa centralnim kontrolerom.

WISE protokol se bazira na MQTT protokolu. Uvođenjem tipova poruka, definisane su oznake unutar MQTT tema za svaki od tipova, a načinom na koji su definisane teme se otvara mogućnost razmene poruka na nivou jedne od funkcionalnosti uređaja. Time je omogućeno pretplaćivanje samo na željenu funkcionalnost sa ciljem dobijanja promena osobina iste, odnosno slanje zahteva radi menjanja neke osobine funkcionalnosti.

Na krajnjoj aplikaciji definisan je prikaz za svaku od funkcionalnosti koja je podržana protokolom. Dobavljanjem niza funkcionalnosti sa uređaja i proverom da li je određena funkcionalnost implementirana protokolom i kom prioritetu pripada, informacije dobijene od nje i komponente za vršenje akcija nad njom, ukoliko te akcije postoje, se prikazuju korisniku.

Prednost ovog rešenja je što centralni kontroler može prepoznati uređaje i u potpunosti upravljati njima čak i ukoliko oni nisu prethodno integrisani u sistem. Pritom, protokol komunikacije opisan ovim radom se bazira na protokolu koji je veoma dobro prihvaćen od strane IoT zajednice po pitanju efikasnosti, što ne dovodi do značajnog usporavanja komunikacije u sistemu.

Zahvalnica

Ovaj rad je delimično finansiran od strane Ministarstva za prosvetu, nauku i tehnološki razvoj Republike Srbije, na projektu broj: TR32014.

ABSTRACT

This paper describes the concept of the solution for displaying the functionality of IP (stands for Internet Protocol) devices to end users of the home automation system in a simplified way. The solution implies a generic representation of the physical properties of the device, whereby device information is supplied using the WISE (stands for WiFi Sensors) protocol. By dividing the functionality of the devices by priority, it is possible to draw the control screens for functionally different devices in an intuitive way. This significantly facilitates the maintenance and expansion of smart home systems for new devices.

Generic representation of functionalities and states of devices in IoT systems

Podacima-vođena arhitektura za prilagodljive energetske mreže zasnovana na IoT uređajima

Nenad Petrović, Đorđe Kocić

***Apstrakt*—Povećanje potrošnje električne energije poslednjih godina donosi nove izazove i iziskuje promene. Postojeći sistemi i infrastruktura bi trebalo da postanu fleksibilniji, sa mogućnošću da rade u veoma dinamičnim uslovima, pri čemu treba da reaguju adekvatno na promene koje nastaju u okruženju. Iz tog razloga, u zadnje vreme se teži evoluciji energetske mreže prema takozvanoj pametnoj mreži. U ovom radu, istražuju se mogućnosti primene modernih informacionih i telekomunikacionih tehnologija u pametnim elektroenergetskim mrežama, oslanjajući se na pristupačne IoT uređaje. Kao rezultat istraživanja, predložena je podacima-vođena arhitektura za prilagodljive energetske mreže koja se oslanja na Internet of Things (IoT) uređaje i dat je opis implementacije najbitnijih komponenti sa pojedinim aspektima evaluacije.**

***Ključne reči*— IoT, edge computing, inženjering modelovanja, mašinsko učenje, pametne mreže**

I. UVOD

Električna energija je ključni faktor koji je doveo do munjevitog tehnološkog razvoja ljudskog društva u prošlom veku [1]. Danas, potreba za električnom energijom postaje sve veća, dok je dostupnost neobnovljivih izvora energije sve manja, što vrši pritisak na postojeće distributivne sisteme koji su potencijalno usko grlo [1, 2]. Preopterećenje sistema može izazvati ozbiljne probleme i dramatično uticati na kvalitet prenosa električne energije. Sa druge strane, uprkos povećavanju potrošnje, korisnici očekuju jeftinije cene električne energije. Stoga postoji potreba za unapređenjem postojećih sistema za distribuciju električne energije i za povećanje njihove fleksibilnosti [2]. Mogućnost adekvatnog prilagođavanja promenama i rad u uslovima dinamičnog opterećenja je glavni zahtev modernih sistema i servisa [3].

Iz tog razloga, poslednjih godina je dosta rada uloženo u transformisanje postojećih distributivnih sistema, pomoću informaciono-komunikacionih tehnologija u tzv. *pametne mreže*. Pametna mreža se definiše kao elektroenergetska mreža sledeće generacije, koja je implementirana u vidu dvosmernog sajber-fizičkog sistema sa ugrađenom računarskom inteligencijom koja iskorišćava prikupljene podatke da kontroliše energetsku mrežu sa ciljem stvaranja čiste, bezbedne, pouzdane, otporne i efikasne energetske mreže koja isporučuje električnu energiju krajnjim korisnicima [1, 2, 4, 5]. Implementacija pametnih mreža postaje od strateškog značaja za mnoge zemlje. Jedna od glavnih karakteristika ovakve mreže je mogućnost detekcije događaja bilo gde u mreži i usvajanja odgovarajuće strategije kao odgovor na novonastale uslove rada i sve to skoro u realnom vremenu [1, 2, 4, 5].

U ovom radu istražuje se mogućnost korišćenja najsavremenijih informacionih i telekomunikacionih tehnologija za primenu u unapređivanju energetskih distributivnih mreža oslanjajući se na *Internet of Things* (IoT) uređaje i prikupljene podatke. Kao rezultat istraživanja, predložena je arhitektura, a pojedini aspekti implementacije i evaluacije su detaljnije prikazani.

II. OSNOVE I SRODNA ISTRAŽIVANJA

A. Arhitektura pametne mreže

U literaturi postoje mnogi opisi strukturalnih komponenti i modela arhitektura pametnih mreža [4-6]. U Tabeli I, dat je sumarni pregled elemenata koji se najčešće sreću i njihove uloge objašnjene. U ovom radu akcenat je na informacionim i komunikacionim tehnologijama, a ne na komponentama za proizvodnju i prenos električne energije.

TABELA I
KOMPONENTE PAMETNE MREŽE I NJIHOVE ULOGE

Komponenta	Uloga
Energetski podsistem	Proizvodnja, prenos i distribucija električne energije
Sloj komunikacije	Žičane i bežične komunikacione mreže koje omogućavaju prenos informacija između komponenata pametne mreže
Merni uređaji	Uređaji koji vrše merenja električnih i drugih veličina od značaja
Podsistem računarske inteligencije	Izvođenje određenih zaključaka na osnovu prikupljenih podataka i donošenje odluka za izvršenje odgovrajućih akcija
Aplikacije i servisi	Različiti tipovi softvera koje koriste operateri i korisnici pametne mreže, a obuhvata funkcije vizuelizacije, nadzora i kontrole

B. Internet of Things (IoT)

Pojam *Internet of Things* (IoT) se odnosi na sistem raznolikih, međusobno povezanih uređaja koji se koriste u svakodnevnom životu koji ima za cilj automatizaciju određenog domena (od kućnih uređaja, preko proizvodnje do

vojnih primena) [2-6]. Ovi uređaji opremljeni su različitim tipovima senzora, kamerama i modulima za pozicioniranje koji generišu različite vrste podataka. Mogu se takođe opremiti i aktuatorima da bi se njima mogla vršiti i kontrola okruženja. U većini slučajeva njihova procesorska moć je ograničena i moraju da komuniciraju sa drugim uređajima (serverima) da bi postigli svoj cilj. Što se tiče komunikacije koriste se različite tehnologije, kratkog dometa (kao što je Bluetooth) i dugog dometa (Wi-Fi, 4G). Trenutno su na pomolu i 5G mobilne mreže koje omogućavaju veću brzinu prenosa, veći kapacitet prenosa i veću pouzdanost, što će biti jako korisno za primenu sa IoT uređajima [7].

Može se primetiti da IoT ima veliki potencijal za primenu u pametnim mrežama [2, 6]. Pametne mreže zahtevaju da merni i aktuatorski uređaji budu distribuirani širom stambenih i industrijskih oblasti da bi prikupljali neophodne podatke i pružali adekvatne odgovore na novonastale promene. IoT sistemi savršeno odgovaraju toj svrsi, imajući u vidu njihove male dimenzije, priuštivost i činjenicu da je internet konekcija danas široko dostupna.

C. Tehnike analize podataka

Kod pametnih mreža, postoji neophodnost da se analizira velika količina podataka prikupljenih IoT i mernim uređajima i da se iz tih podataka izvuče znanje sa ciljem da se detektuju šabloni ili pojava određenih događaja.

U tu svrhu se koriste različite tehnike mašinskog učenja i *data mining-a*. U većini postojećih radova, fokus je na detekciji anomalija u radu i prognozi opterećenja [4]. U ovim slučajevima najčešće se koriste algoritmi za klastering, klasifikaciju, regresiju i pronalaženja pravila asocijacije, izvršenih nad različitim merenim podacima prikupljenim sa pametnih merača, od električnih parametara do vremenskih prilika [4, 5, 6, 8, 9].

Detekcija anomalija je od najveće važnosti jer pruža mogućnost ranog otkrivanja kvarova i otkaza, tako da pametna mreža može brzo da reaguje i odgovori na promene [4, 5]. U radu [5], korišćen je alogritam klasterovanja zajedno sa otkrivanjem pravila asocijacije sa ciljem da se otkriju problematični događaji, kao što je preopterećenje. Sa druge strane, da bi se optimizovao raspored potražnje energije, potreban je precizan dijagram potrošnje korisnika. Ovde prognoza potrošnje ima bitnu ulogu. U [8] i [9], za prognozu potrošnje koristi se regresija bazirana na pomoćnim vektorskim mašinama.

D. Edge computing

Prikupljanje podataka sa IoT uređaja i njihovih senzora je od velike važnosti za monitoring i odlučivanje u pametnim mrežama. Nažalost, klasičan pristup obradi podataka u oblaku ne daje dobre rezultate, jer bi prenošenje velikog broja podataka koje stvaraju IoT uređaji (senzori) u oblak izazvalo velika kašnjenja u sistemu. Sa druge strane, kako pametna mreža raste, sve veći broj IoT uređaja koji se priključuju izaziva još veće kašnjenje.

S obzirom da pametna mreža mora da odgovori na promene u okruženju u približno realnom vremenu, takva kašnjenja su nedopustiva [10, 11]. Iz ovog razloga, *edge computing* se razmatra kao moguće rešenje. Ideja *edge computing-a* je da se obrada i procesiranje podataka prenesu bliže izvorima stvaranja podataka - *edge* serverima, da bi se omogućilo brže vreme reagovanja [10]. Na primer, u [11] je pokazano da se performanse sistema za nadzor pametne mreže mogu poboljšati čak 10 puta pomeranjem obrade podataka bliže mestima gde se podaci generišu.

E. Semantičke tehnologije

Uloga semantičkih tehnnologija je da opiše značenje podataka i veze između njih odvojeno od samog sadržaja i aplikacionog koda. Na taj način se omogućava da i ljudi i mašine mogu da interpretiraju podatke, razmenjuju i izvode zaključke na osnovu njih. U oblasti semantičkih tehnologija, ontologije se koriste za opis koncepata i relacije među njima u okviru nekog domena. Ovi semantički opisi često čuvaju u formi tripleta (*subjekat, predikat, objekat*) korišćenjem RDF[1] standarda. Za izvršavanje upita nad RDF semantičkim bazama tripleta se koristi SPARQL[2]. Izvršavanjem upita nad semantičkom bazom pribavljaju se rezultati koje je dalje moguće koristiti za mehanizme zaključivanja, sa ciljem da se izvede novo znanje na osnovu postojećih činjenica.

U IoT-baziranim sistemima, semantičke tehnologije se mogu iskoristiti na mnogo različitih načina. Jedna od čestih primena jeste ostvarivanje interoperabilnosti heterogenih IoT uređaja [12]. Osim toga, mogu se koristiti u kompleksnijim scenarijima, poput automatskog generisanja koda sa ciljem koordinacije robota [13, 14]. U [15] je prikazan semantički radni okvir za anotaciju rezultata algoritama računarskog vida u IoT-baziranom sistemu za video-nadzor sa ciljem da se omogući zaključivanje o događajima i reaguje na njih. U ovom radu želimo primeniti kombinaciju navedenih pristupa, pri čemu se umesto procesa koordinacije posmatra adaptacija kao proces.

F. Domenski-specifični jezici

Domenski specifični jezici su specijalizovani za rešavanje problema iz određenog domena, a njihove notacije mogu biti tekstualne ili grafičke (u okviru alata za modelovanje). Uglavnom, u IoT-baziranim sistemima se ovakvi jezici koriste da bi smanjilo kognitivno opterećenje korisnika koje proizilazi iz velike raznorodnosti uređaja i kompleksnosti infrastrukture. U ovom slučaju, kodovi napisani u domenski specifičnim jezicima se prevode na specifične komande pojedinih uređaja.

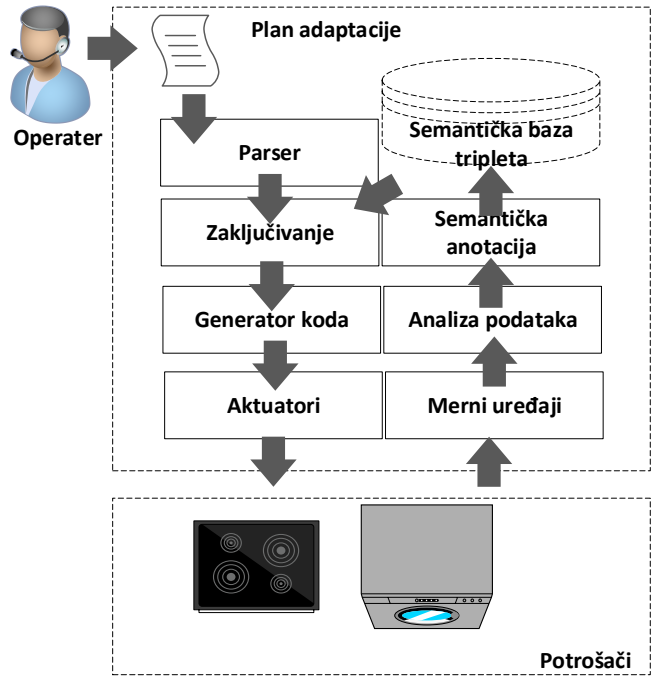
Recimo, u [16] je prikazan EDL jezik za definiciju eksperimenata korišćenjem robotskih IoT uređaja. U kontekstu pametnih električnih mreža, vizuelni alati koji koriste domenski-specifične notacije bi se mogli iskoristiti sa ciljem da se operaterima olakšaju operacije upravljanja. Na ovaj način je omogućena implementacija složenih scenarija bez potrebe da se upušta u implementacione detalje pojedinačnih uređaja. U ovom radu se, konkretno, razmatra modelovanje plana adaptacije kao odgovor pametne mreže na promene iz spoljašnje sredine. Usko povezano postojeće rešenje je Cloud Application Modelling and Execution Language (CAMEL) [17], koji omogućava specificiranje različitih aspekata aplikacija u oblaku, a između ostalog pruža mogućnost modelovanja adaptivnog ponašanja.

[1] https://www.w3.org/RDF/
[2] https://www.w3.org/TR/sparql11-query/

III. PREGLED IMPLEMENTACIJE

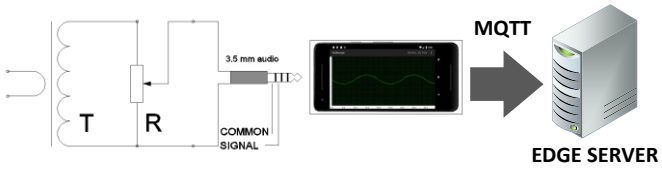
U ovoj sekciji, predložena je arhitektura pametne električne mreže koja se oslanja na IoT uređaje i prethodno navedene tehnologije, a pojedini detalji implementacije detaljnije izloženi.

Arhitektura sistema i pirncip rada: Merenje električnih veličina obavlja se od strane pametnih uređaja za merenje. Ovu ulogu mogu imati mikrokontroleri, single-board računari (poput Raspberry Pi) ili pametni telefoni, kao što je to u našem slučaju. Prednost korišćenja pametnih telefona je u velikom broju dostupnih senzora i ulaza (poput 3.5 mm audio ulaza) Osim toga, njihove punjive baterije i podrška za bežične mobine mreže pružaju mogućnost korišćenja čak i u manje pristupačnim predelima. Zatim, prikupljeni podaci se analiziraju korišćenjem tehnika *data mining-a* i mašinskog učenja. Rezultati dobijeni analizom se semantički anotiraju, tako da se semantičkim zaključivanjem može doći do zaključaka o događajima nastalih u okruženju. Skup akcija koji se izvršava kada su određeni uslovi u okruženju ispunjeni (*plan adaptacije*) se definiše korišćenjem vizuelnog alata za modelovanje koji se oslanja na domenski-specifičnu notaciju. Konačno, na osnovu zadatog plana se generišu komande za specifične uređaje sa ciljem da se odgovori na promene nastale u okolini. Ove komande aktuatori izvršavaju nad potrošačima, ali se sam mehanizam izvršenja komandi i hardverska implementacija aktuatora ne razmatraju u ovom radu. Ilustracija opisanog radnog okvira i principa je data na Sl. 1.



Sl. 1. Podacima-vođen radni okvir za prilagodljive IoT-zasnovane pametne mreže

Pametni merači bazirani na Android platformi: U [18] je prezentovan metod za prikupljanje informacija o električnim merenjima koristeći pristupačne uređaje sa Android platformom. Signali napona i struje se prikupljaju pomoću naponskih i strujnih transformatora sa elektroenergetske mreže. Oba signala se pretvaraju u naponske signale, koje se onda dodatno skaliraju na nivo audio signala posredstvom promenljivih otpornika. Nakon toga signal ide direktno na 3.5 mm audio priključak pametnog uređaja. Pošto većina uređaja baziranih na Androidu podržava stereo ulaz za mikrofon, to u ovom slučaju stvara savršenu dvokanalnu platformu za merenje energetskih signala. Audio sistem uređaja (zvučna kartica) vrši analogno/digitalnu A/D konverziju, tako da se sada podaci mogu obrađivati standardnim metodama obrade digitalnih signala, kao što su algoritmi bazirani na FFT-u. Takođe je korisno snimati i druge podatke koje generiše pametni uređaj kao što su temperatura, vreme i lokacija. Prikupljeni podaci se šalju na *edge* server preko MQTT[3] (Message Queuing Telemetry Transport), lagan, *publish-subscribe* ISO standardizovan protokol za razmenu poruka koji radi povrh TCP/IP protokola. Poruke se šalju kao JSON-kodirani string. U ovom formatu, primer poruke koja sadrži izmerenu vrednost frekvencije električnog signala bi bio: `{"device":"Smarthpone", "sensorType":"frequency", "value":49.9}`. Merni sistem zasnovan na Android pametnim uređajima je ilustrovan na Sl. 2.

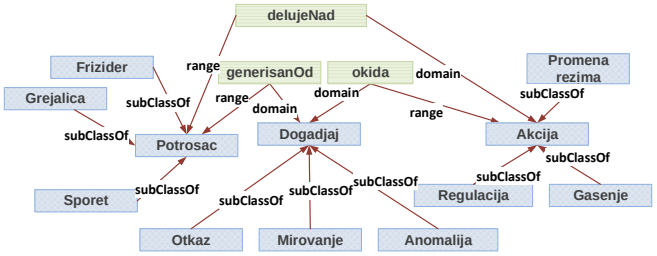


Sl. 2. Merni sistem baziran na Android uređajima

Mehanizmi analize podataka: Za implementaciju mehanizama analize podataka u ovom radu se oslanjamo na TensorFlow za programski jezik Python, biblioteku otvorenog koda za mašinsko učenje. Osim toga, pruža mogućnost izvršenja na GPU, što je pogodno kada je kritično vreme obrade u realnom vremenu. Dva mehanizma su implementirana: 1) detekcija anomalija korišćenjem klasifikacije 2) predviđanje potrošnje zasnovano na regresiji. Klasifikacija je proces identifikacije kom skupu pripada posmatrani uzorak, na bazi trening skupa koji se sastoji od uzoraka čija je pripadnost unapred poznata. Sa druge strane, regresija omogućava da se vrši predviđanje kako se menja vrednost neke zavisne promenljive, kada neka od nezavisnih promenljivih varira. U prvom slučaju, koriste se merenja frekvencije i napona, a treba ih svrstati u jednu od dve kategorije: 1) ok – normalan rad potrošačkog uređaja 2) anomaly – anomalija pri radu. U drugom slučaju koristi se prosečna dnevna temperatura kao nezavisna promenljiva, dok je potrošnja zavisna promenljiva.

Semantički radni okvir: Domenska ontologija (prikazana na Sl. 3) koristi se za semantičku anotaciju rezultata dobijenih nakon analize podataka. Razmatraju se različite vrste događaja koji se mogu detektovati na potrošačkim uređajima: otkazi, anomalije napona, režim mirovanja i slično. Osim toga, za svaki od razmatranih događaja se definiše skup mogućih akcija koje se mogu preduzeti kao reakcija na taj događaj, poput gašenja uređaja, regulacija napona, prebacivanje u režim niske potrošnje.

[3] http://mqtt.org/



Sl. 3. Domenska ontologija za upravljanje u pametnim mrežama

U okviru Listinga I je dat primer SPARQL upita koji se izvršava kada se proverava uslov da li je detektovana anomalija napona na bar jednom potrošaču.

LISTING I
PRIMER SPARQL UPITA IZVRŠENOG PRILIKOM DETEKCIJE ANOMALIJA

```
PREFIX sgc: <http://www.example.com/resources/sgc/>
SELECT ?Dogadjaj
WHERE {
  GRAPH <http://www.example.com/test> {

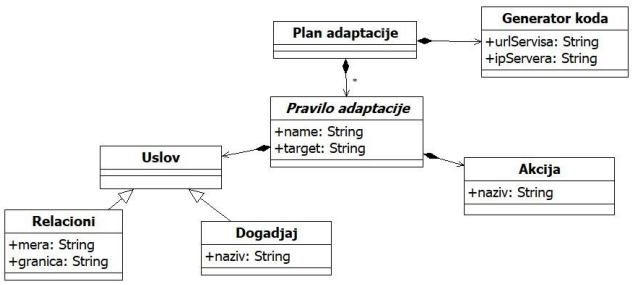
  }
}
```

Vizuelni alat za modelovanje plana adaptacije: Razvijen je korišćenjem Node-RED kao osnove. Node-RED je intuitivni i proširivi radni okvir za povezivanje IoT uređaja, aplikacionih programskih interfejsa i servisa na inovativne načine. Okruženju za modelovanje se pristupa korišćenjem web pretraživača, a pruža jednostavan korisnički interfejs sa proširivom paletom elemenata za modelovanje (čvorova). Domenski-specifična notacija korišćena u okviru alata je data u obliku metamodela na Sl. 4. Metamodel predstavlja model programskog jezika koji definiše strukturu i ograničenja za familiju modela. U ovom radu, koristi se za definisanje adaptacionog plana koji se sastoji od niza pravila adaptacije. Svako pravilo adaptacije ima uslov, cilj i akciju koju treba izvršiti nad ciljem kada uslov bude ispunjen. Ovi uslovi mogu biti konkretni događaji (otkazi, anomalije itd.), ali i relacioni izrazi koji se odnose na granice određenih merenih veličina. Osim toga, svaki plan adaptacije mora posedovati i jedan element generatora koda, koji sadrži kao parametre IP servera na kome se generator nalazi i URL za poziv servisa. Na ovaj način je omogućeno da se odgovarajući generator koda odabere zadavanjem parametra, bez modifikacije samog alata za modelovanje, što olakšava proširivost i prilagođavanje za različite platforme pametnih mreža u budućnosti. Okruženje za modelovanje u okviru Node-RED je prikazano na Sl. 5.



Sl. 4. Metamodel plana adaptacije

Zaključivanje i generisanje komandi: Izvršava se po algoritmu datom u Listingu II, inspirisanom mehanizmom predstavljenom u [19]. Svaki uslov se prevodi u SPARQL upit koji se izvršava nad semantičkom RDF bazom znanja. Ukoliko upit vrati rezultat *true*, onda se generiše odgovarajući kod i dodaje u skriptu komandi koje aktuatori treba da izvrše nad potrošačima. Konačno, generisane komande se šalju ciljanim uređajima takođe kao MQTT poruke.

LISTING II
ALGORITAM GENERISANJA KOMANDI

Ulaz: merenja, plan adaptacije
Izlaz: skripta komandi
Steps:
1. Pribaviti sva pravila adaptacije iz plana adaptacije
2. Analizirati senzorske podatke;
3. Izvršiti semantičku anotaciju rezultata iz Koraka 2;
4. For each AdaptationRule
5. uslov:=izvršiUpit(AdaptationRule.condition);
6. If (uslov is true)
7. then generisati komandu za ciljani uređaj;
8. end for each
9. end

IV. EVALUACIJA I REZULTATI

U ovoj sekciji predstavljeni su rezultati ostvareni u eksperimentima koristeći prethodno opisani radni okvir, iz dve različite perspektive. Prvo se razmatraju performanse mehanizama za detekciju anomalija i predviđanje potrošnje. Nakon toga, analizira se vreme neophodno za procesiranje u određenim koracima prilikom generisanja koda, sa ciljem da se utvrdi sposobnost sistema da blagovremeno reaguje na promene. Eksperimenti su izvršavani na serveru sa procesorom AMD Ryzen 7 1700X octa-core CPU 3.80GHz, 64GB DDR4 RAM i NVIDIA Quadro P2000 GPU sa 4GB VRAM.

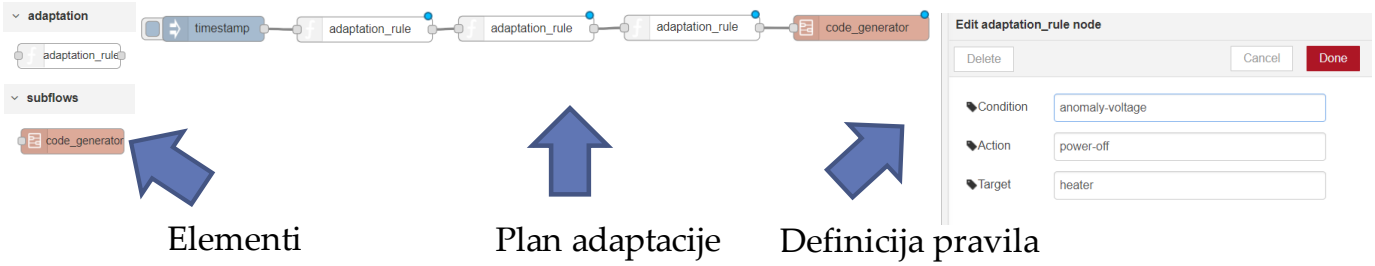
U Tabeli II I Tabeli III, prikazani su rezultati dobijeni prilikom korišćenja predstavljenog pristupa za detekciju anomalija i predviđanje potrošnje, implementirani korišćenjem TensorFlow u Python programskom jeziku. Za različite eksperimente, prikupljeni podaci su podeljeni u dva disjunktna skupa u različitim odnosima – trening i test skup.

TABELA II
REZULTATI DETEKCIJE ANOMALIJE UPOTREBOM KLASIFIKACIJE

Veličina trening skupa	Veličina test skupa	Tačno klasifikovani/ veličina testa [%]
50	100	84.93
75	100	89.58
100	100	92.17

TABLE III
REZULTATI PERDVIĐANJA POTROŠNJE KORIŠĆENJEM REGRESIJE

Veličina trening skupa	Veličina test skupa	Relativna greška [%]
50	100	18,31
100	100	16,29
150	100	15,21



Sl. 5. Okruženje za modelovanje plana adaptacije u okviru Node-RED

Kao što se može videti iz tabela, oba mehanizma analize podataka daju zadovoljavajuće rezultate u različitim odnosima veličine trening i test skupa, s tim da daju bolje rezultate za veće trening skupove, do određene granice. Međutim, nakon daljeg povećanja veličine trening skupova postoji tendencija overfitting-a, pri čemu se ne dolazi do boljih rezultata.

Sa druge strane, u Tabeli IV je dat pregled ostvarenih vremena procesiranja u koracima analize podataka i generisanja koda za različit broj pravila adaptacije u okviru plana adaptacije prilikom detekcije anomalija. Svako pravilo se odnosi na različit potrošački uređaj, dok su podaci merenja prikupljeni tokom 600 sekundi. Što se tiče analize podataka, prikazani rezultati predstavljaju sumu vremena za trening i test (u razmeri: 70% trening skup, 30% test skup), a razdvojeno su razmatrana vremena procesiranja dobijena primenom CPU i GPU. Sva merenja vremena su data u sekundama kao prosek deset uzastopnih merenja u identičnim uslovima.

Prema dobijenim rezultatima, vreme koje je potrebno za analizu podataka povećava se sa brojem razmatranih potrošačkih uređaja iz razloga što više uređaja generiše veću količinu podataka za obradu. Osim toga, i generisanje koda traje duže iz razloga što je potrebno izvršiti veći broj SPARQL upita u slučaju većeg broja pravila adaptacije, s obzirom da svako pravilo sadrži uslov koji se prevodi u SPARQL upit, a i veći je broj parametara koje je neophodno pribaviti i umetnuti u šablon komandi. Može se zapaziti da je u nekim slučajevima vreme generisanja koda za isti broj pravila različito, a to proizilazi iz činjenice da se komande generišu samo onda kada je uslov pravila adaptacije ispunjen, a ne uvek. Što se tiče poređenja performansi izvršenja na CPU i GPU, može se uočiti da se detekcija anomalija izvršava do oko 2.4 puta brže na GPU nego na CPU, pri čemu se ubrzanje povećava sa porastom količine podataka.

TABELA IV
PREGLED VREMENA PROCESIRANJA U SLUČAJU DETEKCIJE ANOMALIJA

Broj pravila	Analiza podataka (CPU) [s]	Analiza podataka (GPU) [s]	Generisanje koda[s]
1	4.31	3.11	1.67
2	7.28	3.67	2.43
2	7.54	3.95	1.91
3	9.82	4.07	3.08

V. ZAKLJUČAK I BUDUĆA ISTRAŽIVANJA

U ovom radu, razmotrene su tehnologije koje omogućavaju adaptaciju u pametnim električnim mrežama koje se oslanjaju na sveprisutne IoT uređaje. Vizuelni alat za modelovanje plana adaptacije daje mogućnost realizacije kompleksnih scenarija bez potrebe poznavanja implementacionih detalja samih uređaja. Sa druge strane, implementirani mehanizmi za detekciju anomalija napona i prognozu potrošnje pokazuju zadovoljavajuće rezultate, pri čemu vreme izvršenja dobijeno na GPU u slučaju detekcije anomalija deluje obećavajuće, čak i za primene u skoro realnom vremenu. Naravno, planiramo da isprobamo i različite implementacione varijante i testiramo njihove performanse. Osim toga, cilj nam je da realizujemo kompletne merne sisteme koristeći još jeftinije uređaje, poput Raspberry Pi i Arduino.

Međutim, u budućnosti ćemo se fokusirati više na implementaciju aktuatorskih mehanizama, koji nisu predstavljeni u ovom radu. Još jedan bitan aspekat koji nije obuhvaćen ovim radom, a od velike je važnosti za IoT-zasnovane pametne mreže, jeste bezbednost, s obzirom da IoT uređaji komuniciraju uglavnom bežičnim kanalima koji su česta meta napada. U ovom slučaju, napadi mogu imati posledice katastrofalnih razmera, poput nestanka električne energije, ali i oštećenja infrastrukture i ugrožavanje živih bića [20]. Prema tome, još jedna od tema naših budućih istraživanja biće upravo bezbednost.

ZAHVALNICA

This work has received funding from the European Union's Horizon 2020 Framework Programme for Research and Innovation under the Grant Agreement No 645220, project RAWFIE (Road-, Air- and Water- based Future Internet Experimentation). Ovaj rad je delimično finansiran od strane Ministarstva prosvete, nauke i tehnološkog razvoja Republike Srbije u okviru projekta III44006.

ABSTRACT

The dramatic increase of demand for electric power in recent years has introduced new challenges and requirements. The existing infrastructure and systems should become more flexible, able to operate in highly dynamic environments and react adequately to changes. For that reason, the existing electric grid evolves towards Smart Grid architecture. In this paper, we explore how state-of-art information and communication technologies can be exploited to enable adaptability in Smart Grid relying on affordable IoT devices. As an outcome, we propose a data-driven architecture of adaptable Smart Grid based on IoT devices. Moreover, some implementation and evaluation aspects are also presented.

Data-driven architecture for adaptable Smart Grid based on IoT devices

Automatizacija radnog okruženja za ispitivanje složenih audio sistema

Filip Uzunović, Branko Đorđević, Nenad Pekez, Jelena Kovačević

***Apstrakt*—U ovom radu je predstavljeno automatizovano radno okruženje za ispitivanje složenih audio sistema, čijom upotrebom se smanjuje vreme neophodno za ispitivanje do 35 %. Kao precizan i pouzdan uređaj za efikasno ispitivanje ovih sistema koji zamenjuje skupa rešenja na tržištu, korišćen je RT-AG (RT – Audio Graber). RT-Executor koji omogućava automatsko izvršavanje ispitnih slučajeva, predložen je kao programska podrška ispitivanju. U radu je takođe navedeno i na koji način je unapređena sama procedura za ispitivanje.**

***Ključne reči*—Audio sistemi, Ispitivanje, Verifikacija, Automatizacija**

I. Uvod

Audio tehnologije su doživele ogroman napredak od početne dvokanalne (stereo) prezentacije, preko više kanalnih prezentacija, pa sve do savremenih 3D objektnih prezentacija.

Kanalne prezentacije zapravo predstavljaju tradicionalan način prenosa i reprodukovanja zvuka. Svaki kanal je dizajniran tako da se reprodukuje na tačno određenom mestu u sistemu u odnosu na slušaoca. 2D zvučna scena kombinacija je velikog broja pojedinačnih zvučnih elemenata, dijaloga snimljenih na setu, muzike snimljene u studiju itd. Ovi elementi distribuirani su na nekoliko audio zapisa u skladu sa standardizovanom konfiguracijom zvučnika [1]. Krajnji rezultat ovog procesa jeste skup kanala, gde svaki od njih predstavlja sadržaj jednog od zvučnika. Međutim takav signal pravilno će se reprodukovati na samo jednoj izlaznoj konfiguraciji zvučnika odnosno zvučnoj sceni. Naravno postoji mogućnost reprodukcije takvog signala i na drugim zvučnim scenama za koje nije predviđen, ali to zahteva još neke dodatne korake u obradi a sam doživljaj zvuka neće biti prostorni ukoliko zvučnici nisu dobro postavljeni. Danas su audio sistemi bazirani na kanalima i dalje veoma rasprostranjeni i vrlo stabilni, iako postoji sve veća težnja ka sistemima za reprodukciju 3D zvuka.

Za opisivanje prostiranja 3D zvuka koristi se određen broj 3D audio objekata [2]. Za razliku od kanala čije pozicije su tačno definisane, pozicija objekata u prostoru može biti:

- potpuno nezavisna od lokacije prisutnih zvučnika u sistemu
- mogu varirati tokom vremena za modelovanje pokretnih objekata kao što je avion koji se kreće iznad glave slušaoca

Jedno od rešenja za univerzalno i efikasno kodovanje i pružanje kvalitetnog prostornog zvučnog sadržaja jeste 3D objektno orijentisano renderovanje. Osim što je u stanju da obezbedi visoki kvalitet prostornog zvuka, ima mogućnost i da objedini mnoštvo 3D audio formata od nižih stereo, 5.1, do 22.1. Na ovaj način se postiže i kompatibilnost novih formata sa prethodnim uređajima.

Kako su nove generacije audio tehnologija donele određene promene, dovele su i do povećanja složenosti sistema. Samim tim proces verifikacije i ispitivanja ovih rešenja postaje složeniji i predstavlja sve veći izazov za inženjere. Podatak koji najbolje oslikava složenost ovog procesa jeste porast broja ispitnih slučajeva od nekoliko stotina do nekoliko hiljada ispitnih slučajeva. Metode manualnog ispitivanja postaju neefikasne u primeni, kako sa stanovišta utrošenog vremena, tako i pouzdanosti vezane za ocenu ispravnosti testiranog sistema. Ručno ispitivanje je zavisno od ljudske interpretacije, odnosno podložno greškama QA inženjera prilikom ocene ispravnosti sistema, usled nedovoljnog poznavanja specifikacije sistema ili iskustva. Sa druge strane, primena metoda ručnog testiranja oduzima značajan deo vremena potrebnog za razvoj sistema. Usled težnje proizvođača da obezbede konkurentnost na tržištu, razvoj sistema u ovoj oblasti je u velikoj meri uslovljen potrebom za skraćenjem vremena pojavljivanja proizvoda na tržištu [3]. Jedan od načina da se to postigne jeste skraćenje procesa ispitivanja. Sa druge strane, nedovoljno ispitan proizvod dovodi do smanjenja kvaliteta, što negativno utiče na konkurentnost. Da bi se obezbedilo kraće vreme proizvodnje i pružio bolji kvalitet, potrebno je više pažnje posvetiti analizi kvaliteta sistema i unaprediti proces ispitivanja, čime bi se poboljšao njegov kvalitet. Time se javlja potreba za automatizacijom ovog procesa, što predstavlja glavnu temu rada.

U ovom radu predstavljeno je radno okruženje za automatizaciju ispitivanja složenih audio sistema. Prvo je naveden opis hardverskog sistema i tipične ispitne procedure, koja je do sada primenjivana, kao i njeni nedostaci koje ponuđeno radno okruženje otklanja. Potom je u narednim poglavljima predstavljena sama realizacija predloženog rešenja. Opisuje se RT-Audio Graber (RTAG), uređaj razvijen u okviru RT-RK instituta, koji služi za reprodukciju i snimanje audio signala. Zatim je objašnjeno kako je tipična

Filip Uzunović – Istraživačko-razvojni Institut RT-RK, Novi Sad, Srbija (e-mail: filip.uzunovic@rt-rk.com)
Branko Đorđević – Istraživačko-razvojni Institut RT-RK, Novi Sad, Srbija (e-mail: branko.djordjevic@rt-rk.com)
Nenad Pekez – Istraživačko-razvojni Institut RT-RK, Novi Sad, Srbija (e-mail: nenad.pekez@rt-rk.com)
Jelena Kovačević – Istraživačko-razvojni Institut RT-RK, Novi Sad, Srbija (e-mail: jelena.kovacevic@rt-rk.com)

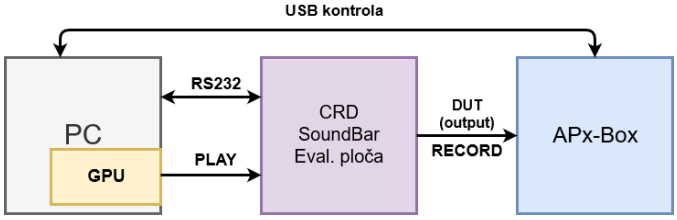
ispitna procedura unapređena i navedeno je na koji način je ova procedura automatizovana. Ističe se kako upotreba RT-Executora, koji osim za automatizaciju izvršavanja ispitnih slučajeva, pomoću svojih ugrađenih algoritama omogućava i analizu snimljenih izlaza. Na kraju su prikazani rezultati primene predloženog radnog okruženja.

II. TIPIČNA ISPITNA PROCEDURA

Kompanije koje obezbeđuju algoritme (eng. IP provider) u isto vreme obezbeđuju i pakete za ispitivanje tih algoritama. Tipična struktura paketa za ispitivanje se sastoji od dokumentacije, test materijala i alata koji se koriste.

Kompanija, kao što je npr. Dolby, obezbeđuje QA inženjeru upitnik čijim popunjavanjem se dobija spisak ispitnih slučajeva koje je neophodno izvršiti kako bi se verifikovala ispravnost ispitivanog uređaja. QA inženjer specificira o kom se konkretnom uređaju radi, koliko izlaznih kanala podržava taj uređaj, koji audio izlazi postoje, koje izlazne konfiguracije zvučnika podržava taj uređaj itd. Popunjavanjem upitnika generiše se spisak ispitnih slučajeva, ispitnih signala za svaki slučaj kao i konfiguracione poruke koje je neophodno poslati uređaju prilikom samog izvršavanja. Na osnovu ovih informacija QA inženjer piše Python skriptu koja služi kao šablon po kom se kreira Audio Precision (APx) projekat u kom se izvršavaju testovi.

Sledeći korak je postavljanje i povezivanje hardverskog sistema, čija struktura je predstavljena na Sl. 1.



Sl. 1Prikaz tipičnog hardverskog sistema

APx je višekanalni audio analizator, koji podržava 8 ili 16 simultanih analognih ulaza i izlaza, napravljen za dizajniranje i ispitivanje korisničkih uređaja [4]. Prikaz APx uređaja dat je na Sl. 2

Sl. 2 Audio Precision APx585

U ispitnoj proceduri nalazi se u ulozi mernog instrumenta, koji reprodukuje ili snima audio signale i ima svoju softversku podršku. PC vrši upravljanje grafičkom karticom i izvršavanje testova po koracima:

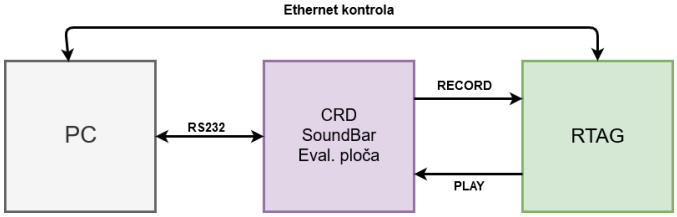
- podešavanje samog uređaja slanjem konfiguracionih poruka
- reprodukovanje ispitnog signala preko grafičke kartice
- merenje i analiza izlaza snimljenih APx mernim instrumentom sa ploče/uređaja

Svaki od navedenih koraka izvršava se zasebno za svaki ispitni slučaj, a samo izvršavanje je ručno. Izvršavanje jednog testa traje oko 5 min a broj ispitnih slučajeva može da ide od nekoliko stotina do nekoliko hiljada. Slanje konfiguracionih poruka je usko vremenski ograničeno i ukoliko se ne ispoštuje tačno definisan vremenski interval neće biti uspešno. Sve ovo zahteva potpunu pažnju i konstantnu prisutnost QA inženjera, uz činjenicu da oduzima značajan broj radnih sati. Takođe sam APx, zbog svoje kompleksnosti, važi za veoma skup uređaj. Samim tim, evidentna je potreba i javlja se prostor za unapređenjem ove procedure i njenu automatizaciju čija realizacija će biti predstavljena u narednom poglavlju.

III. REALIZACIJA REŠENJA

A. *Hardverski sistem*

Hardverski sistem, prikazan na Sl. 3 unapređen je zamenom APx-a sa audio uređajem RTAG, koji je razvijen u razvojno istraživačkom institutu RT-RK. RTAG predstavlja eksternu zvučnu karticu koja obezbeđuje ulaze i izlaze audio signala, do i sa računara, pod kontrolom kompjuterskog programa/aplikacije [5]. Podržava kako reprodukciju tako i snimanje audio signala do 8 kanala na frekvencijama do 192kHz/32b. Konekcija sa računarom ostvaruje se putem Ethernet-a. Primarno RTAG je napravljen da se koristi u kombinaciji sa DSP evaluacionim pločama, ali je moguće koristiti ga u paru sa krajnjim korisničkim audio uređajima kao što su Blu-Ray, Sound Bar, AVR itd.



Sl. 3 Prikaz unapređenog hardverskog sistema

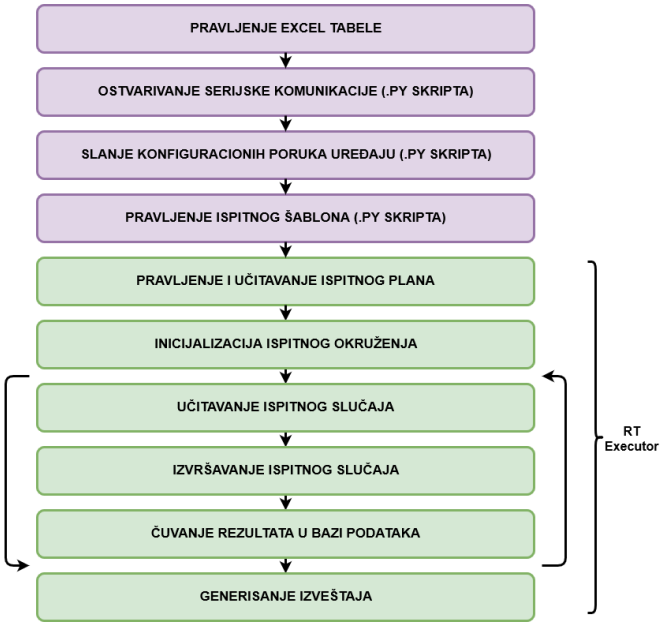
B. *Unapređena ispitna procedura*

Redosled kreiranja i izvršavanja automatskih test slučaja predstavljen je na Sl. 4. Za programsku podršku ispitivanju odabran je RT-Executor, program razvijen u istraživačko razvojnom institutu RT-RK, čime je postignuta automatizacija procesa samog izvršavanja ispitnih slučajeva. RT-Executor je samostalna aplikacija, osposobljena da kontroliše veliki broj softverskih i hardverskih modula neophodnih za automatsko testiranje [6]. Podržava ispitivanje po principu “crne kutije”.

Na osnovu specifikacije ispitivanog uređaja pišu se testovi kojima će se ispitati da li uređaj uspešno izvršava sve

predviđene operacije. Ispitni slučajevi se prave na osnovu šablona, napisanog u programskom jeziku Python, i redom izvršavaju sledeće korake za svaki ispitni slučaj:

- otvaranje serijskog porta
- prebacivanje MCU (Microcontroller Unit) u UART mode (Universal Asynchronous Reciever-Transmitter)
- slanje odgovarajućih konfiguracionih poruka MCU
- reprodukciju odgovarajućeg testnog signala
- upisivanje konfiguracionih poruka iz MCU na DSP (Digital Signal Procesor)
- snimanje izlaza



Sl. 4 Prikaz unapređene ispitne procedure

Slanje konfiguracionih poruka obavlja se putem serijske komunikacije, a poruke za svaki ispitni slučaj mogu biti različite. Poruke se dobijaju pomoću Python skripte koja parsira svaki ispitni slučaj posebno. Prethodno isparsirane poruke za promenu režima rada i individualne poruke, prvenstveno se šalju MCU koji ih dalje upisuje na DSP. Ove korake takođe izvršava zasebna Python skripta koja se poziva unutar testa za taj konkretan ispitivan slučaj.

Kada su napravljeni ispitni slučajevi koji pokrivaju kompletnu funkcionalnost uređaja i kada se proveri da su ispravno napisani od njih se pravi projekat koji se pokreće u RT-Executor-u.

RT-Executor smešta rezultate ispitnih slučajeva u bazu podataka iz koje generiše izveštaj u vidu HTML (Hyper Text Markup Language) stranice. Rezultat izvršavanja može biti jedan od tri statusa: PASS, FAIL, UNRESOLVED koji jasno govore da li je ispitni slučaj uspešno izvršen (PASS), neuspešno izvršen (FAIL) ili je njegov slučaj nerazrešen (UNRESOLVED). Ukoliko je isitni slučaj iz određenih razloga neuspešno izvršen ili je status nerazrešen, QA inženjer kroz sam izveštaj može da vidi i opis greške koja postoji. Da bi proglasili da je uređaj uspešno ispitan, svi ispitni slučajevi moraju biti "PASS". U slučaju da nakon provere i ponavljanja ispitnih slučajeva rezultati ponovo nisu pozitivni, QA inženjer prijavljuje grešku.

C. *Analiza snimljenih izlaza*

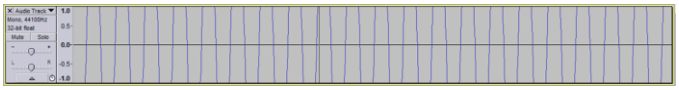
RT-Executor pomoću svojih ugrađenih alata omogućava jednostavnu analizu audio izlaza sa ispitivanog uređaja, po svakom snimljenom kanalu. Jedan od takvih alata je Audio Quality Meter (AQM).

AQM je softverski dodatak za RT-Executor koji u sebi ima audio algoritme za prepoznavanje različitih audio artifakta kao što su isecanje, prekidi, zamrzavanje i izostanak audio signala. Na kraju svakog ispitnog slučaja vrši se pozivanje određenog AQM audio algoritma koji nam javlja da li je prisutan neki od audio artifakta. Ukoliko ne postoje, RT-Executor proglašava ishod ispitnog slučaja kao PASS, ili u suprotnom će ishod biti FAIL.

Algoritam odsustva zvuka analizira audio signal za nultu vremensku aktivnost. Ako audio signal nedostaje duže od navedenog vremena, detektuje se odsustvo. Postoje dva tipa algoritama odsustva: provera odsutnosti u vremenskim i frekvencijskim domenima. Algoritam takođe podržava dodavanje nivoa buke u dB (podrazumevano = -60 dB) koju treba zanemariti tokom analize. Primer odsustva zvuka u audio signalu prikazan je na Sl. 5

Sl. 5 Primer odsustva zvuka u audio signalu

Isecanje predstavlja izobličenje talasnog oblika koji se javlja kada je pojačalo preopterećeno i pokušava da isporuči izlazni napon ili struju van svojih opsega. Algoritam za audio isecanje u RT-Executoru vrši analizu u vremenskim i frekvencijskim domenima i detektuje periode kada je signal isečen zbog vrlo visokog nivoa amplitude. Primer takvog signala dat je na Sl. 6



Sl. 6 Primer isecanja u audio signal

IV. REZULTATI

Predloženo radno okruženje i ispitna procedura primenjena je prilikom ispitivanja Sound Bar uređaja, za odabranu konfiguraciju zvučnika 5.1.2, na audio tehnologiji Dolby Atmos HT 1.6.2.

PRIMENJIVANA METODA ISPITIVANJA	BROJ ISPITNIH SLUČAJEVA	VREME POTREBNO ZA ISPITIVANJE JEDNOG SLUČAJA	BROJ PONAVLJANIH TESTOVA	UKUPNO VREME POTREBNO ZA ISPITIVANJE UREDAJA
STARA METODOLOGIJA	138	5 min	15	~ 13h
NOVA METODOLOGIJA	138	3 min	3	~ 8,5 h

Sl. 7 Rezultati ispitivanja Sound Bar uređaja i konfiguraciju zvučnika 5.1.2

U tabeli sa Sl. 7 jasno se vidi kako ponuđeno rešenje utiče na pouzdanost samog ispitivanja. Na broj ispitnih slučajeva koji se moraju ponavljati najviše je uticao faktor ljudske greške koji je u novoj proceduri, upotrebom RT-Executora, uspešno eliminisan. Broj ovakvih ispitnih slučajeva sveden je na minimum i smanjen čak 5 puta. Ukupno vreme neophodno za ispitivanje uređaja smanjeno je za više od 30%. Ušteda vremena još je značajnija ukoliko se uzme u obzir podatak da je ukupan broj ispitnih slučajeva neophodnih za verifikaciju Dolby tehnologija porastao sa 4226 za Dolby Atmos HT 1.5 na 6539 za Dolby Atmos HT 1.6.2.

V. Zaključak

Ponuđeno radno okruženje zajedno sa celokupnim sistemom za automatsko ispitivanje eliminiše sve nedostatke ručnog ispitivanja. Automatizacijom ovog procesa dobija se značajna ušteda na vremenu. Čak i do 35% manje vremena je potrebno kako bi se verifikovala ispravnost jednog uređaja. Takođe, kako se testovi automatski izvršavaju, QA inženjer ne mora konstantno nadgledati proces, što mu ostavlja prostor da obavlja još jedan posao istovremeno čime se dodatno dobija na vremenu. Sve ovo smanjuje vreme potrebno za pojavljivanje samog proizvoda na tržištu. Upotreba RTAG-a, čija cena je manja čak i do 30 puta u odnosu na prethodno korišćeni APx, donosi značajnu finansijsku uštedu.

VI. Zahvalnica

Ovaj rad je delimično finansiran od strane Ministarstva za nauku i tehnologiju Republike Srbije, na projektu tehnološkog razvoja broj TR32029.

Abstract

This paper presents an automated framework for testing complex audio systems, whose use reduces the time required for testing up to 35%. RT-Audio Graber was used as an accurate and reliable device for efficient testing of these systems, which replaces the expensive solution on the market. RT-Executor, which allows the automatic execution of test cases, is proposed as a software support for testing. The paper also outlines the way in which the test procedure itself has been improved.

Automated framework for testing of complex audio systems

Realizacija aplikacija za konkurentno snimanje i reprodukciju multimedijalnog sadržaja na uređajima sa Android operativnim sistemom

Marko Milovanović, Marčeta Zoran, Milan Ačanski, Nikola Vranić, Istraživačko-razvojni institut RT-RK, Novi Sad, Srbija

***Apstrakt* — Android je najpopularniji operativni sistem i platforma za mobilne telefone i tablet računare. Milioni mobilnih uređaja širom sveta danas koriste Android kao primarnu softversku platformu. Iako je prvenstveno dizajniran za uređaje sa ekranom osetljivim na dodir, Android postaje deo širokog spektra platformi, pa tako i digitalnih prijemnika. Opremljeni bogatim multimedijalnim opcijama i podrškom za instalaciju besplatnih Android aplikacija, digitalni prijemnici su odlično rešenje za nadogradnju običnog televizora na Smart TV. Snimanje multimedijalnog sadržaja, kao jedna od opcija Androidovog multimedijalnog podsistema, podržano je za više kontejnerskih formata, ali Android trenutno ne podržava snimanje datoteka u MPEG-TS formatu, najpopularnijem formatu u oblasti digitalne televizije. U ovom radu opisano je proširenje multimedijalnog podsistema za snimanje TS tokova, koje je iskorišćeno za potrebe realizacije aplikacija, čija je glavna funkcionalnost mogućnost istovremenog snimanja i reprodukcije multimedijalnog sadržaja.**

***Ključne reči* — set-top box, Media Muxer, Media Codec, MPEG-TS, stagefright**

I. UVOD

Nakon pojave televizije u boji sredinom pedesetih godina 20-og veka, prva značajna evolucija u oblasti televizije bila je pojava digitalne televizije. Tranzicija sa analogne na digitalnu televiziju započeta je početkom 21-og veka i danas je digitalna televizija gotovo u potpunosti preuzela primat.

Uporedo sa ovim globalnim trendom, razvijali su se i digitalni TV prijemnici (eng. set-top box, STB), čija je prvobitna uloga bila prijem i konverzija digitalnog u analogni signal, čime je omogućeno emitovanje digitalne televizije na starijim, analognim TV uređajima. Njihov razvoj bio je direktno povezan sa napretkom tehnologije. Vremenom su dodate nove funkcionalnosti. Elektronski programski vodič, roditeljska zaštita, izbor omiljenih kanala i snimanje postali su standardni deo implementacije svakog STB uređaja.

Nakon više od 10 godina na tržištu, Android operativni sistem nalazi primenu na velikom broju platformi, pa tako i na STB uređajima. Jedan od razloga za njegovo prihvatanje je poznato okruženje i brojne funkcionalnosti koje krajnji korisnici već poseduju na svojim mobilnim telefonima – pristup internetu, izvršavanje aplikacija najšireg skupa funkcionalnosti i mnoge druge. [1]

Snimanje multimedijalnog sadržaja jedna je od standardnih funkcionalnosti digitalnog TV prijemnika. Najkorišćeniji format za prenos digitalnih TV podataka u oblasti digitalne televizije naziva se MPEG-TS (skraćeno TS). Android trenutno ne podržava snimanje TS tokova, pa je za potrebe realizacije aplikacija iskorišćen jedan predlog proširenja mltimedijalnog podsistema.Glavna zamisao realizovanih aplikacija je da simuliraju rad STB uređaja. Aplikacije imaju mogućnost istovremenog snimanja i reprodukcije multimedijalnog sadržaja u TS formatu. Snimanje prosleđenih audio i video tokova u odredišnu datoteku sa strane aplikacije podražava snimanje sadržaja jednog ili više TV servisa sa strane STB uređaja, dok reprodukcija sa strane aplikacije imitira emitovanje sadržaja jednog TV servisa sa strane STB uređaja. Realizovane su dve aplikacije: native, napisana u C/C++ programskim jezicima i Java Android aplikacija, napisana u Java programskog jeziku. Obe aplikacije poseduju isti skup funkcionalnosti, ali se razlikuju u sprezi koju pružaju korisniku.

Na samom početku dat je opis radnog okruženja. Par reči biće posvećeno digitalnoj televiziji i formatima za prenos digitalnih TV podataka. U četvrtom poglavlju opisana je arhitektura Androidovog sistema. Peto poglavlje daje opis proširenja sistema za snimanje, kao i realizovanih aplikacija, dok je šesto poglavlje posvećeno testiranju funkcionalnosti navedenih aplikacija.

II. RADNO OKRUŽENJE

Kako se Android razvijao, javila se potreba i mogućnost korišćenja Androida na širokom spektru platformi. Google je

Marko Milovanović, Istraživačko razvojni institut RT-RK, Narodnog Fronta 23a, Novi Sad, Srbija (telefon: 381-21-480-1234, email: marko.milovanovic@rt-rk.com)

Nikola Vranić, Istraživačko razvojni institut RT-RK, Narodnog Fronta 23a, Novi Sad, Srbija (telefon: 381-21-480-1238, email: nikola.vranic@rt-rk.com)

Zoran Marčeta, Istraživačko razvojni institut RT-RK, Narodnog Fronta 23a, Novi Sad, Srbija (telefon: 381-21-480-1297, email: zoran.marceta@rt-rk.com)

Milan Ačanski, Istraživačko razvojni institut RT-RK, Narodnog Fronta 23a, Novi Sad, Srbija (telefon: 381-21-480- 1256, email: milan.acanski@rt-rk.com)

razvio porodicu prenosnih uređaja baziranih na Androidu, Google Nexus, u koju su uključeni mobilni telefoni (Nexus 6P, Nexus 5X), tablet uređaji (Nexus 9), kao i plejeri za reprodukciju multimedijalnog sadržaja (Nexus Player). [2]

Uređaj na kom je testirano dato proširenje sistema, kao i realizovane aplikacije, je navedeni multimedijalni plejer, Nexus Player.

Na samom početku je bilo neophodno skinuti Android projekat (eng. Android Open Source Project, AOSP). Svi neophodni sistemski rukovaoci, kao i verzije projekta za ovaj uređaj nalaze se na sajtu. Aktuelna verzija Android operativnog sistema dostupna za Nexus Player je Android Oreo.

Nakon skidanja koda i drajvera, i primene zakrpe nad kodom u cilju proširenja sistema za snimanje, bilo je neophodno izvršiti prevođenje projekta. Uspostavljane okruženja za prevođenje postiže se upotrebom lunch komande, koja je zadužena za odabir određene konfiguracije okruženja za generisanje programske slike, dok se komandom make započinje proces prevođenja.

Java aplikacija je u velikoj meri realizovana u razvojnom okruženju Android Studio, ali proces prevođenja kao i pokretanje aplikacije nije bilo moguće ostvariti u njemu. Razlog za to je upotreba AOSP biblioteka, neophodnih za izradu aplikacija. Budući da Android Studio koristi drugačiji sistem za prevođenje u odnosu na Android projekat, projekat je prebačen u stablo AOSP-a uz par izmena kako bi se izvršio proces prevođenja.

III. Digitalizacija televizije

Digitalizacija televizije je fenomen koji prati nekoliko povezanih trendova:

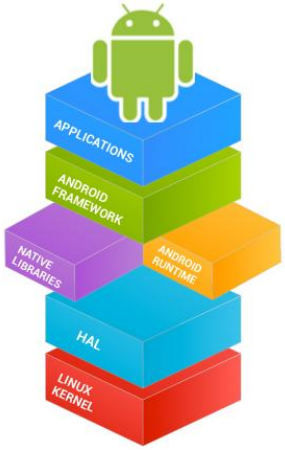
- konstantno povećavanje dimenzije ekrana
- smanjivanje veličine uređaja
- konstantno povećanje rezolucije slike
- integracija multimedijalnih i internet tehnologija
- nove digitalne usluge i aplikacije na TV ekranu

Razvoj televizije i razvoj različitih oblasti se, u svetlu gore navedenih oblasti, nadopunjuju.

Digitalna televizija obuhvata prenos televizijskog signala od emitera do gledaoca digitalnim putem, korišćenjem digitalnih modulacionih tehnika, u obliku digitalnog prenosnog toka u okviru kojeg se vremenski multipleksirano prenose paketi vezani za audio i video sadržaje, metapodatke i dodatne sadržaje koji se odnose na više servisa. Format za prenos digitalnih TV podataka, kontejnerski format, oblikovan je kao bitski tok sa tačno definisanom paketskom organizacijom. Postoji više standarda za kontejnerske formate kojima se prenose multimedijalne informacije, a najčešće korišćen standard za kontejnerske formate koji se koriste u digitalnoj televiziji je MPEG-2 Verzija 1. Ovim standardom definisana su dva tipa kontejnerskog formata: MPEG-PS format, koji se koristi kod prenosnih medijuma koji nisu podložni pojavi grešaka, i MPEG-TS format, koji se koristi kod prenosnih medijuma podložnim pojavi grešaka pri prenosu emisionim putem. [3]

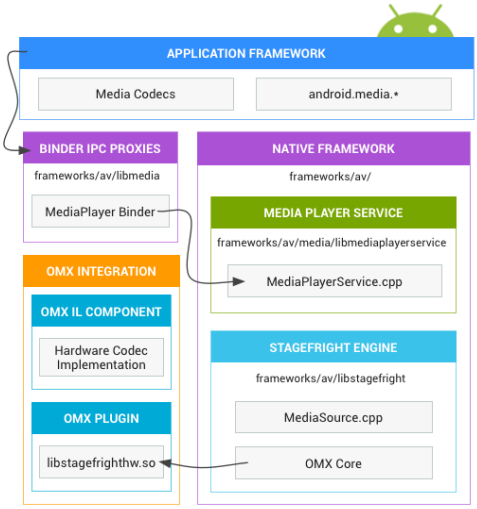
IV. Arhitektura Androida

Android operativni sistem sadrži specifičnu programsku podršku koja je podeljena u nekoliko suštinski različitih slojeva (Sl. 1), a prednosti su brojne: jasno definisanje uloge svakog sloja omogućuje visok stepen modularnosti i enkapsulacije, izolacija pojednih slojeva olakšava paralelizaciju razvoja, moguća je verifikacija svakog sloja ponaosob, što olakšava pronalaženje grešaka i povećava kvalitet programske podrške i dr. [4]



Sl. 1. Arhitektura Android operativnog sistema

Arhitektura multimedijalnog podsistema Androida je po ugledu na celokupnu arhitekturu takođe slojevita, sa puno nivoa indirekcije (Sl. 2).



Sl. 2. Multimedijalni podsistem

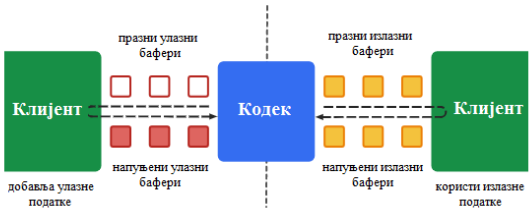
Aplikacije komuniciraju sa nižim delovima sistema preko sloja programskih okvira, koji nudi interfejse za pristupanje i manipulaciju nad multimedijalnim sadržajem. Ispod ovog sloja, stvari se komplikuju jer delovi sloja programskih okvira komuniciraju sa native komponentama preko JNI interfejsa.

Zahtevi iz Java programske podrške se prosleđuju MediaPlayer servisu putem Inter Process Comunication (IPC) poziva. U okviru MediaPlayer servisa pravi se komponenta za reprodukciju audio i video sadržaja odgovarajućeg tipa, a osnovna komponenta je StagefrightPlayer. [5] On koristi

StagefrightEngine, u kom su smeštene sve funkcionalnosti vezane za reprodukciju i snimanje audio i video datoteka. Deo StagefrightEngine-a je Stagefright biblioteka, čije su najbitnije komponente MediaCodec, MediaExtractor i MediaMuxer. MediaCodec je klasa koja apstrahuje enkoder ili dekoder, MediaExtractor je klasa koja služi za dohvatanje traka iz prosleđenog toka i čitanje podataka iz njih, a MediaMuxer je klasa namenjena za snimanje tokova u fajl. [6]

Ove klase su deo android.media API-ja, pa je moguće praviti multimedijalne aplikacije koje ne koriste celokupan definisani stek, već samo deo od Stagefright biblioteke na dole. Prednost ovakvog pristupa je brže izvršavanje aplikacija ali, zbog kompleksnosti nižih slojeva i njihove slabe dokumentovanosti, potrebno je uložiti dodatno programersko vreme.

Na slici 3 je na uprošćen način prikazan rad kodeka. Kodek procesira ulazne podatke kako bi generisao izlazne podatke. Podaci se obrađuju asinhrono, koristeći ulazne i izlazne bafere. Klijent šalje zahtev za dobijanje praznog ulaznog bafera od kodeka, zatim ih puni podacima, dobijenim najčešće od MediaExtractor klase, i šalje ih kodeku na dekodovanje. Kodek nakon dekodovanja primeljenih podataka puni jedan od izlaznih bafera. Klijent šalje zahtev za dobijanje izlaznog bafera, koristi njegov sadržaj i vraća ih natrag kodeku. Dekodovani podaci se mogu prikazati korišćenjem odgovarajućih apstrakcija za prikaz audio/video sadržaja. Osim prikaza podaci se mogu proslediti MediaMuxer klasi koja će vršiti njihov upis u fajl. Na taj način vršimo snimanje željenog multimedijalnog sadržaja. [7]



Sl. 3. Dekodovanje podataka pomoću kodeka

V. OPIS REŠENJA

A. *Proširenje sistema za snimanje*

Formati koje MediaMuxer trenutno podržava su MPEG4, Webm i 3GP. Dakle, Android ne podržava snimanje sadržaja u najkorišćenijem formatu za prenos digitalnih podataka – MPEG Transport Stream.

Glavni deo komponente MediaMuxer je writer, tj. instanca bilo koje klase koja nasleđuje MediaWriter apstraktnu klasu. U korišćenoj verziji Android-a, mukser je imao mogućnost kreiranja dve vrste MediaWriter-a: MPEG4Writer i WebmWriter, ali istraživanjem ostatka biblioteke uočena je i klasa MPEG2TSWriter. Najveći deo izmena koda vezan je za ovu klasu, ali određene izmene je trebalo odraditi i u klasi MediaMuxer. U MPEG2TSWriter klasi nalazi se sva funkcionalnost specifična za snimanje sadržaja u TS formatu. Proširenjem je omogućeno snimanje TS fajla sa jednim programom i po jednom audio i video trakom, po ugledu na podržano snimanje MP4 formata. Moguće je snimanje samo sa kodecima Advanced Audio Coding (AAC) za audio trake i Advanced Video Coding (AVC) za video trake, jer Android trenutno podržava samo reprodukciju TS-a sa navedenim kodecima. [8]

Izmene u kodu realizovane su u vidu zakrpe (eng. patch) koju je trebalo primeniti nad kodom Android projekta pre same izrade aplikacija.

B. *Native aplikacija, MediaRecorder*

Glavni delovi native aplikacije su klase DeltaPlayer i MediaRecorder. Za potrebe ovog rada napisana je biblioteka DeltaPlayer i ona je namenjena isključivo reprodukciji multimedijalnog sadržaja. Reprodukcija sadržaja u TS formatu je podržana u Androidu, ali samo uz korišćenje AVC kodeka za video i AAC kodeka za audio. DeltaPlayer preveden je kao deljena biblioteka libdeltaplayer.

Osnovna funkcionalnost MediaRecorder klase je snimanje audio i video tokova izvorišnog fajla u odredišni fajl pomoću muksera, odnosno objekta klase MediaMuxer. Nakon inicijalizacije date klase, poziva se njena start() metoda, u kojoj se pokreće mukser i startuje nit nad threadLoop() metodom, koja je zadužena za glavnu obradu, snimanje odgovarajućih tokova u fajl (Sl. 4).

```
void* MediaRecorder::threadLoop(void* arg) {
    while (true) {
        AMediaExtractor_getSampleTrackIndex();
        AMediaExtractor_getSampleTime();
        AMediaExtractor_getSampleFlags();

        buffer = malloc(bufferSize);

        //! Fill input buffer with coded data
        if (AMediaExtractor_readSampleData(buffer) == -1) {
            break;
        }

        //! Setup buffer for muxing
        buffer = ...

        //! Mux data
        AMediaMuxer_writeSampleData(buffer);

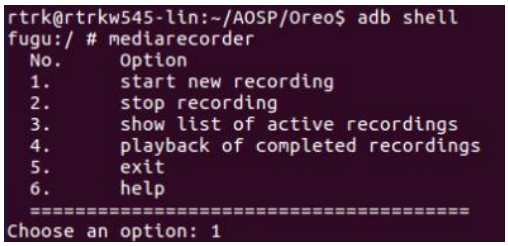
        free(buffer);

        //! Read next data
        AMediaExtractor_advance();
    }

    return NULL;
}
```

Sl. 4. Telo threadLoop() metode

Ulazna tačka aplikacije je funkcija main(). Pregled svih funkcionalnosti prikazuje se korisniku putem komandne linije, preko koje se i obavlja potrebna komunikacija (Sl. 5).



Sl. 5. Izgled native aplikacije

Aplikacija ima sledeće funkcionalnosti:

- pokretanje novog snimanja
- zaustavljanje snimanja
- pregled snimaka u toku
- reprodukcija završenih snimaka

Aplikacija je konkurenta, jer je omogućeno snimanje više tokova istovremeno. Pokretanje novog snimanja podrazumeva kreiranje novog objekta klase MediaRecorder, pri čemu putanje do izvorišnog i odredišnog fajla zadaje korisnik. Prilikom zaustavljanja snimanja korisnik unosi redni broj koji predstavlja identifikator na osnovu kojeg se dohvata odgovarajući objekat klase MediaRecorder, a zatim poziva stop() metoda nad datim objektom. Pregled snimaka u toku daje korisniku uvid u informacije vezane za aktivne snimke, odnosno snimke u toku. Kod reprodukcije završenih snimaka, najpre se prikazuju informacije o snimcima. Korisnik zatim unosi redni broj snimka, na osnovu kojeg se iz baze dohvata putanja do fajla, odnosno snimka koji treba prikazati. Nakon toga instancira se komponenta za reprodukciju audio i video sadržaja, odnosno objekat klase DeltaPlayer, čijem konstuktoru se prosleđuje putanja do fajla koji je potrebno prikazati. Nakon inicijalizacije, komponenta za reprodukciju je spremna za pokretanje. Funkcionalnosti vezane za rad sa snimcima su:

- reprodukcija snimljenog sadržaja
- pauziranje reprodukcije snimljenog sadržaja
- nastavak reprodukcije snimljenog sadržaja
- zaustavljanje reprodukcije snimljenog sadržaja

Izvorni fajl u kom se nalazi klasa MediaRecorder, kao i funkcija main(), prevedeni su u izvršni fajl mediarecorder. Zajedno sa bibliotekom libdeltaplayer, izvršni fajl je prebačen na NexusPlayer pomoću adb alata. Za pokretanje native aplikacije najpre treba pristupiti terminalu uređaja, a zatim ukucati ime programa koji je potrebno pokrenuti.

C. *Java Android aplikacija, MediaRecorderApp*

Sve funkcionalnosti native aplikacije, implementirane su i grafičko-korisničkoj sprezi. Od postojeće native aplikacije napravljena je deljena biblioteka, uz određene izmene. Sama aplikacija sastoji se iz dve aktivnosti: MainActivity i PlaybackActivity. U MainActivity klasi obezbeđene su sve funkcionalnosti vezane za snimanje multimedijalnog sadržaja, dok je PlaybackActivity klasa zadužena za reprodukciju snimljenog sadržaja. Da bi aplikacija komunicirala sa native bibliotekama, bilo je neophodno uspostaviti vezu posredstvom JNI interfejsa jer nije moguće direktno pozivanje C koda u Java kodu. Zato sa jedne strane imamo Java klasu sa deklaracijama potrebnih metoda koje se koriste u navedenim aktivnostima (obratiti pažnju na ključnu reč native), a sa druge strane korespodentne C funkcije. Prilikom statičke inicijalizacije Java klase vrši se učitavanje biblioteke libmediarecorderjni, u kojoj se nalaze implementacije svih nabrojanih metoda, napisane na C programskom jeziku. Za generisanje zaglavlja u kom se nalaze deklaracije C funkcija koristi se alat javah.

Nakon prevođenja unutar stabla AOSP-a, kreirani .apk fajl se prebacuje na Nexus Player pomoću adb alata. Izgled početnog ekrana aplikacije prikazan je na Sl. 6.

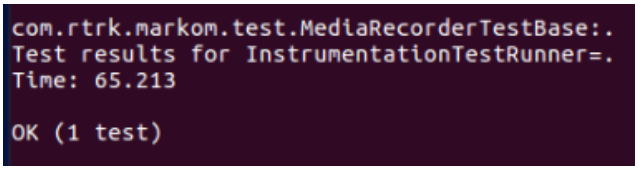
Sl. 6. Izgled početnog ekrana aplikacije

VI. TESTIRANJE

Nakon realizacije aplikacija bilo je neophodno verifikovati ispravnost njihovih funkcionalnosti. Napravljena je test aplikacija MediaRecorderTest, koja ne predstavlja ništa drugo nego aplikaciju sa testovima, realizovanu pomoću test klasa.

Sami testovi realiozovani su kao test metode klase MediaRecorderTestBase. Ona nasleđuje ActivityInstrumentationTestCase2 klasu koja je deo android-test biblioteke.

MediaRecorderTestBase klasa sadrži jednu test metodu, testPlayVideo(), u okviru koje se najpre vrši snimanje audio i video tokova iz izvorišnog u odredišni fajl sa predefinisanih putanja, a nakon snimanja testiraju se sve funkcionalnosti vezane sa rad sa snimcima. Prevođenje se obavlja na identičan način kao i prevođenje MediaRecorderApp aplikacije. Za pokretanje test aplikacije, najpre treba pristupiti terminalu uređaja, a zatim uneti odgovarajući komandu kojom se pokreću testovi. Ono što je neophodno navesti je ime test paketa u kom se nalaze napisani testovi i naziv *runner* klase koja ih pokreće. Klasa koja je korišćena za pokretanje testova je android.test.InstrumentationTestRunner i ona je navedena unutar manifesta date aplikacije. InstrumentationTestRunner najpre instancira objekat klase MediaRecorderTestBase, a zatim pokreće njene test metode, odnosno testPlayVideo() metodu. Po završetku testova ispisuje se naziv klase u okviru koje se nalaze test metode, vreme njihovog izvršavanja i broj testova sa konačnim rezultatom (Sl. 7).



Sl. 7. Rezultati testova

VII. ZAKLJUČAK

Nakon proširenja multimedijalnog podsistema za snimanje TS tokova, realizovane su dve varijante komponente za reprodukciju audio i video sadržaja, jedne u obliku native aplikacije, MediaRecorder i druge u obliku Java Android aplikacije, MediaRecorderApp. Obe aplikacije poseduju iste funkcionalnosti, ali se razlikuju u načinu komunikacije sa korisnikom, odnosno sprezi koji pružaju. Glavna odlika ovih komponenti je simultano snimanje i reprodukcija multimedijalnog sadržaja, čime se simulira rad digitalnih TV prijemnika u jednom od režima njihovog rada.

Jedna od mogućnosti u pogledu unapređenja datih aplikacija bila bi istovremena reprodukcija više snimaka, čime bi se simulirao rad STB uređaja u režimu emitovanja više TV servisa, zatim unapređenje interfejsa, kao i uvođenje dodatnih funkcionalnosti karakterističnih za STB uređaje.

ZAHVALNICA

Ovaj rad je delimično finansiran od strane Ministarstva za prosvetu, nauku i tehnološki razvoj Republike Srbije, na projektu broj: TR32029.

ABSTRACT

Android is the most popular operating system and platform for mobile phones and tablets. Millions of mobile devices around the world today use Android as the primary software platform. Although primarily designed for touch screen devices, Android is becoming part of a broad spectrum of platforms, including digital receivers. Equipped with rich multimedia options and support for the installation of free Android applications, digital receivers are a great solution for upgrading a standard TV to Smart TV. Media recording, one of the functionalities of the Android multimedia subsystem, is supported for multiple container formats, but Android currently does not support recording in the MPEG-TS format, the most popular format in the field of digital television. This paper describes the extension of the multimedia subsystem for recording TS streams, which is used in applications, whose main functionality is concurrent media recording and playback.

Applications for concurrent media recording and playback on Android devices

Razvoj mobilne aplikacije zasnovan na testovima korišćenjem XCTest okruženja

Dražen Drašković

***Apstrakt* – U ovom radu opisana je implementacija mobilne aplikacije kviz znanja za iOS platformu sa akcentom na testiranju takve aplikacije. Aplikacija je projektovana kao sistem sa *Model View Controler* (MVC) arhitekturom. Tokom razvoja aplikacije korišćena je metodologija planiranja i izvršavanja testova u toku implementacije, a kao alat za pisanje testova korišćeno je XCTest okruženje. Razvoj aplikacija zasnovan na testovima je vrlo važna tehnika kod softverskih inženjera, pošto podiže kvalitet softvera i smanjuje nedostatke u softveru. U istraživanju su korišćene strategije bele kutije. Realizovani su jedinični testovi za testiranje logike aplikacije i jedinični testovi za testiranje korisničkog interfejsa. Dobijena pokrivenost koda realizovanim jediničnim testovima je 68.85%, a pokrivenost testovima korisničkog interfejsa je 75.02%.**

***Ključne reči* – testiranje softvera, razvoj mobilne aplikacije, *Test Driven Development*, jedinično testiranje, testiranje korisničkog interfejsa, testiranje performansi.**

I. Uvod

Razvojem mobilnih tehnologija povećala se i potreba za razvojem specifičnih alata i okruženja. Najpopularnije platforme za mobilne uređaje današnjice su Android i iOS. Prema podacima iz prvog kvartala 2019. godine ukupan broj aplikacija na portalu Google Play bio je oko 2.1 miliona, a ukupan broj aplikacija na portalu App Store oko 1.8 miliona mobilnih aplikacija [1]. Android i iOS imaju primat i u broju korisnika, sa oko 85% i 13% tržišta respektivno [2].

Aplikacije zastarevaju zbog promena tehnologija, a usled nedostatka vremena i resursa da se aplikacija piše iz početka, prebacivanje aplikacije sa jednu na drugu tehnologiju često je podložno velikom broju grešaka u programskom kodu. Pored toga jako je bitna pouzdanost aplikacije, koja se postiže unapred definisanim procesom testiranja. Da bi se zaštitili od kasnijih grešaka, softverski inženjeri su počeli da pišu testove u sklopu programskog koda aplikacije (eng. *Test Driven Development*, skraćeno: TDD*)* ili neposredno pre pisanja programskog koda funkcionalnosti aplikacije. TDD ciklus obuhvata učitavanje testnih podataka, pokretanje delova programskog koda aplikacije sa učitanim podacima i potvrđivanje rezultata testa. Potrebno je da se nakon izvršenog testa dobije očekivani rezultat ili se rade izmene na programskom kodu i proces refaktorizacije.

Dražen Drašković – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: drazen.draskovic@etf.bg.ac.rs).

Cilj ovog rada bio je da se prikažu prednosti pisanja i izvršavanja testova tokom ciklusa razvoja aplikacije za mobilnu platformu. Postoji dosta alata i biblioteka za testiranje iOS aplikacija tokom samog ciklusa razvoja, a jedna od njih je XCTest. To je biblioteka koja služi za razvoj aplikacije korišćenjem testova bele kutije. Jedinični testovi predstavljaju formu testiranja, gde se testovi pišu za manje celine softvera koji se razvija. Sa XCTest je moguće pisati jedinične testove za testiranje logike aplikacije i testove za testiranje korisničkog interfejsa. U razvoju aplikacije osim XCTest biblioteke, korišćeni su programski jezici Python i Swift i MySQL relaciona baza podataka za čuvanje podataka. Kao mobilna aplikacija, koja prati realizovan proces testiranja, implementirana je igra kviz znanja sa nekoliko funkcionalnosti.

U drugom poglavlju ovog rada prikazan je pregled postojećih mobilnih aplikacija sa sličnom tematikom i kratak opis korišćenih tehnologija. U poglavlju III opisane su realizovane funkcionalnosti mobilne aplikacije. Poglavlje IV prikazuje ključne implementacione detalje, a poglavlje V proces testiranja, od dizajniranja test plana i test primera, do izvršavanja testova i analize dobijenih rezultata. Na kraju rada dat je zaključak.

II. Pregled postojećih rešenja i korišćenih tehnologija

U ovom poglavlju dat je pregled postojećih najpopularnijih mobilnih aplikacija sa kvizovima i njihova uporedna analiza. Sve aplikacije koje su obuhvaćene ovom analizom su besplatne za korišćenje.

A. Pregled postojećih kviz mobilnih aplikacija

QuizUp [3] je kviz sa velikim izborom kategorija pitanja. Na raspolaganju su teme iz oblasti filma, muzike, sporta, kulture, nauke i drugih. Korisnici mogu pristupiti ovoj aplikaciji korišćenjem svog naloga na nekoj drugoj društvenoj mreži poput Facebook-a ili Twitter-a. Na osnovu toga ova kviz aplikacija omogućava korisniku i da izazove svoje prijatelje koje ima na društvenoj mreži.

DK Quiz [4] je aplikacija koja pokriva preko 100 tema i podtema iz oblasti istorije, nauke ili umetnosti. Može se igrati samostalno ili protiv prijatelja sa društvenih mreža. Takođe, aplikacija pravi rang listu, pa se mogu uporediti rezultati sa drugim učesnicima kviza.

Quiz Your Friends [5] je aplikacija u kojoj izazivate u kvizu

prijatelja. Pozivnica za učešće u kvizu se može poslati prijateljima, može se igrati protiv nekog nepoznatog korisnika, videti rezultat ostalih korisnika, ali i napraviti kviz sa svojim pitanjima.

Logos Quiz [6] je kviz za prepoznavanje logoa svetskih kompanija. Ova aplikacija omogućava igranje protiv pravog protivnika, ili protiv kompjuterskog inteligentnog agenta. Ova kviz aplikacija ima nivoe, pa kako se prelaze lakši nivoi, kviz postepeno postaje sve teži.

Trivia Crack [7] je kviz u kome se na slučajan način na početku kviza dobija jedna od šest mogućih kategorija pitanja. Svaka igra se sastoji od pet pitanja. Algoritam igre je takav da ukoliko se što brže odgovori, igrač dobija više poena. Može se videti kako protivnik napreduje po tome kako se ikonica kreće na traci iznad prostora sa pitanjima. Pitanja su različite težine i shodno tome donose različit broj bodova. Ova igra se može igrati sa prijateljem koji ima aktivan nalog na društvenoj mreži Facebook, tako što ga lično pozovete, ili protiv slučajno odabrane osobe, koja se trenutno nalazi unutar kviza i želi da otpočne novu igru.

U tabeli I dat je uporedni prikaz mobilnih aplikacija sa kvizovima znanja, kao i funkcionalnosti koje su podržane.

TABELA I
UPOREDNI PRIKAZ MOBILNIH APLIKACIJA SA KVIZOVIMA

Funkcionalnost	QuizUp	DK Quiz	Quiz Your Friends	Logos Quiz	TriviaCrack
Izbor kategorija pitanja	Da	Ne	Ne	Ne	Da
Logovanje preko društvenih mreža	Da	Da	Da	Da	Da
Pozivanje prijatelja	Da	Ne	Ne	Ne	Da
Izazivanje prijatelja na igru	Da	Da	Da	Da	Da
Upoređivanje rezultata sa drugima	Ne	Da	Da	Da	Ne
Postavljanje kviza na društvenu mrežu	Ne	Ne	Da	Ne	Ne
Nivoi u kvizu	Ne	Da	Ne	Da	Da
Prikaz trenutno aktivnih prijatelja u igri	Da	Ne	Ne	Ne	Da
Slanje kviza prijateljima	Ne	Da	Da	Ne	Ne
Merenje brzine odgovora	Ne	Ne	Ne	Ne	Da
Prosečan broj pitanja u kvizu po jednoj partiji	20	20	10	34	5
Unos pitanja od strane korisnika	Da	Ne	Ne	Da	Ne
Igranje bez konekcije na internet	Da	Da	Da	Da	Da

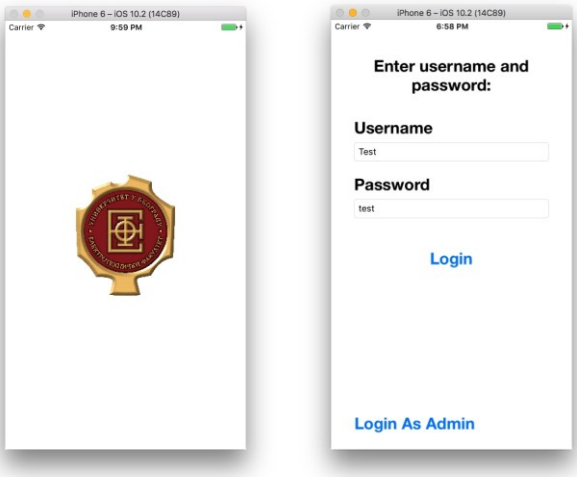
B. Pregled korišćenih tehnologija

Swift je objektno orijentisani programski jezik, koji služi za razvoj Mac i iOS aplikacija. Dizajniran je da bude kompatabilan sa Objective C jezikom. Neke od važnih karakteristika Swift jezika su: brži je od Objective C i Python programskog jezika, poseduje closure, generike i tipsko zaključivanje, ne zahteva stvaranje zasebnih interfejsa i implementacionih fajlova za prilagođene klase i strukture i lako obrađuje velike nizove. Takođe, definicija klase i strukture su u potpisu fajla, a spoljni interfejs te klase i strukture je automatski dostupan. Koristi Objective C runtime, omogućavajući Objective C, C++ i Swift kod u okviru jednog programa, tako da aplikacije koje su već napravljene korišćenjem Objective C jezika mogu da se menjaju pomoću Swift jezika.

Python je programski jezik opšte namene i pripada grupi jezika visokog nivoa. Prednosti Python jezika su: dobra čitljivost koda, sintaksa koja omogućava programerima da izraze koncepte u manje linija koda nego što je moguće u jezicima kao što su C++ ili Java, zatim dinamičko određivanje tipa podataka i automatsko upravljanje memorijom. Ovaj jezik ima veliku i sveobuhvatnu standardnu biblioteku. Takođe, ovaj jezik podržava više programskih paradigmi: objektno orijentisano programiranje, imperativno programiranje, funkcionalno programiranje i proceduralno programiranje. Jedan od nedostataka ovog programskog jezika je u brzini. On je sporiji nego kompajlerski jezici, kao što je na primer C.

III. OPIS REALIZOVANIH FUNKCIONALNOSTI

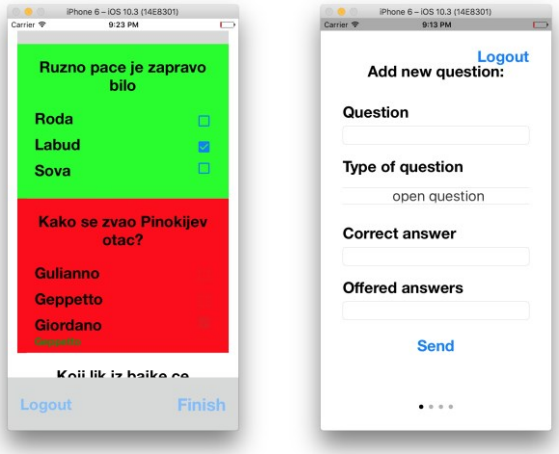
Aplikacija ima intuitivan korisnički interfejs koji je u skladu sa drugim popularnim iOS aplikacijama koje se svakodnevno koriste. Prilikom pokretanja aplikacije pojavljuje se početni ekran i mogućnost da korisnik odabere da li želi da se uloguje na sistem ili da se registruje ukoliko je nov korisnik sistema, kao što je prikazano na Sl. 1. Za obe funkcionalnosti urađena je validacija podataka.



Sl. 1. Uvodni ekran i ekran za logovanje postojećeg korisnika sistema.

Realizovanoj aplikaciji mogu pristupati dva tipa korisnika: standardni korisnici i administratori. Nakon uspešnog logovanja korisnika, on dobija mogućnost da odabere trenutno dostupan kviz i da odgovara na pitanja. Kviz se završava nakon što istekne vreme kviza ili nakon što korisnik završi kviz pre isteka predviđenog vremena. Ukoliko se administrator uloguje, on dobija korisnički meni sa više privilegija od standardnog korisnika. Trenutno podržane

funkcionalnosti administratora u ovoj mobilnoj aplikaciji su: kreiranje kviza, dodavanje pitanje u kviz, kreiranje novog korisnika i pregled rezultata postojećih korisnika. Ako administrator želi da doda novo pitanje, potrebno je da: unese tekst pitanja, odabere tip pitanja, tačan odgovor i u slučaju da je tip pitanja izbora jednog od više ponuđenih odgovora, potrebno je da unese i ponuđene odgovore. Ako ne ispoštuje potrebna pravila za unos pitanja, pitanje neće biti unešeno u bazu. Na Sl. 2 (levo) prikazan je završeni kviz od strane standardnog korisnika, a na Sl. 2 (desno) je prikazan unos pitanja od strane administratora sistema.



Sl. 2. Prikaz završenog kviza i provera odgovora od strane sistema i prikaz unosa pitanja od strane administratora

IV. Implementacioni detalji

Realizovani softverski sistem sastoji se iz aplikacije, baze podataka, API interfejsa (eng. *Application Programming Interface*) i testova. Serverski deo aplikacije pisan je u skladu sa RESTful API i napravljen je tako da može da na zahtev dobijen od aplikacije smesti podatak u bazu. Kroz API je moguće dodati novog korisnika u bazu, proveriti da li su korisnički kredencijali validni, upisati rezultat, odnosno odgovor korisnika u bazu, dodati novo pitanje i druge funkcionalnosti koje su opisane u poglavlju III. Tokom pisanja koda, vodilo se računa da kod bude čitak i da jedna funkcija ima jednu funkcionalnost. Takođe, funkcije su logički povezane u klase. Aplikacija je logički podeljena na deo za administratora i deo za standardnog korisnika.

Kontroleri prikaza su temelj arhitekture mobilne aplikacije. Svaki kontroler prikaza upravlja delom aplikacije korisničkog interfejsa, i obavlja interakciju između tog interfejsa i podataka koji su mu potrebni da ih prikaže. Kontroleri prikaza olakšavaju prelaz između različitih delova korisničkog interfejsa.

UIViewController klasa definiše metode i svojstva koji upravljaju prikazima i događajima, prelaze iz jednog kontrolera prikaza do drugog. U potklasu UIViewController dodaje se prilagođeni kod koji treba da sprovede ponašanje aplikacije. Postoje dva tipa UIViewContollera:

- Prilagođeni kontroleri prikaza - upravljaju diskretnim delovima aplikacije.
- Kontejnerski kontroleri ekrana - prikupljaju informacije iz drugih kontrolera prikaza (engl. *child view contoller*) i predstavljaju ih na način koji olakšava navigaciju ili predstavlja sadržaj tih kontrolera prikaza.

U aplikaciji su korišćeni prilagođeni kontroleri prikaza i kontejnerski kontroler prikaza. *UITableView* kontroler je korišćen za prikaz pitanja u aplikaciji, a *UIPageView* kontroler za navigaciju između stranica administratorskog dela aplikacije. *UITableView* prikazuje listu stavki u jednoj koloni. *UITableView* je podgrupa *UIScrollView*, koja omogućava korisnicima da se vertikalno kreću kroz tabelu. *UITableView* se sastoji od ćelija koje su izvedene iz *UITableViewCell* i koje mogu biti podrazumevane ili prilagođene. Mogu se kombinovati različite ćelije. Sastoje se od sadržaja, zaglavlja i podnožja. Visina može da se određuje dinamički i statički.

UIPageView kontroler omogućava korisnicima da se kreću prevlačenjem između njegovih stranica. *UIPageView* kontroler se sastoji iz niza kontrolera prikaza koji su međusobno nezavisni i svaki upravlja sopstvenim prikazom. Navigaciju može kontrolisati programski aplikacija ili korisnik koristeći pokrete na ekranu. Kada se kreće od stranice do stranice, kontroler koristi prelaz koji je naveden da animira promene.

Za komunikaciju sa serverom se koristi *NSURLSession*. *NSURLSession* klasa i srodne klase pružaju API za preuzimanje sadržaja preko HTTP-a. Ovaj API nudi podršku za autentifikaciju i daje mogućnost da se u pozadini preuzimaju podaci kada aplikacija nije aktivna ili dok se na glavnoj niti radi nešto drugo.

Kada se koristi *NSURLSession* API, aplikacija stvara niz sesija, od kojih svaki koordinira grupu zadataka povezanih sa prenosom podataka. U okviru svake sesije aplikacija dodaje niz zadataka. Svaka sesija predstavlja zahtev ka određenoj URL adresi. *NSURLSession* je asinhroni. Ako se koristi podrazumevano podešavanje sa delegatom, potrebno je, kada se prenos završi uspešno ili sa greškom, obezbediti blok završetka koji vraća podatke u aplikaciju. *NSURLSession* API podržava tri vrste sesija:

- Podrazumevane sesije rade na glavoj niti i blokiraju izvršavanje svega ostalog. Čuvaju podatke i u keš memoriji i na disku.
- Prolazne sesije ne čuvaju nikakve podatke na disku, već se sve čuva u keš memoriji.
- Pozadinske sesije su slične podrazumevanim sesijama, osim što je poseban proces upravljanja svim prenosima podataka.

NSURLSession klasa podržava tri vrste zadataka: za prenos podataka, za skidanje sa servera, i za postavljanje na server. Zadaci za prenos i prijem podataka preko *NSData* objekta namenjeni su za kratke, često interaktivne zahteve iz aplikacije na server. Zadaci za skidanje podataka i zadaci za slanje podataka preuzimaju, odnosno šalju podatke u obliku datoteke i imaju podršku za preuzimanje/slanje u pozadini.

V. TESTIRANJE APLIKACIJE

Testovi su podeljeni na jedinične testove logike apikacije, testove korisničkog interfejsa (skraćeno: UI testovi) i testove performansi. Prva grupa testova obuhvata proveru osnovnih funkcionalnosti na nivou testiranja tehnikom bele kutije. Druga grupa testova pokazuje da li su svi očekivani elementi prisutni i da li se očekivani tekst nalazi unutar tih elemenata. Rađeni su i testovi performansi da bi se videlo koliko je vremena potrebno da se izvrši neka funkcija.

UI testovi testiraju između ostalog da li je neki element na odgovarajućoj poziciji na ekranu i da li je navigacija kroz aplikaciju do određenog prikaza implementirana kako je zamislila osoba koja je zadužena za UX (eng. *User Expiriance*). Ovo su vrlo korisni testovi posebno kada se radi naknadni proces testiranja nakon nekog refaktorisanja koda ili dodavanja neke nove funkcionalnosti u aplikaciji. Jedinični testovi testiraju da li su kontroleri prikaza povezani pravilno i da li server vraća očekivane vrednosti.

Pravila za pisanje testova koja su definisana su: testovi treba da su brzi, da su izolovani koliko god da je to moguće od ostatka sistema, da su postojani, svaki put kada se izvrše da treba da daju isti rezultat i idealno treba da su napisani pre samog pisanja koda, što je i krajnji cilj ovakvog procesa testiranja prilikom razvoja. U tabelama II i III dat je prikaz nekih značajnih jediničnih testova i UI testova.

TABELA II
PRIKAZ REALIZOVANIH JEDINIČNIH TESTOVA

Funkcija	Stanje u sistemu	Šta testiramo
testLoginFuncTrue()	Forma za logovanje, uneti podaci postojećeg korisnika	Logovanje korisnika koji postoji
testLoginFuncFalse()	Forma za logovanje, uneti podaci korisnika koji ne postoji	Logovanje korisnika koji ne postoji
testRegisterFuncTrue()	Popunjena forma za registraciju (kor. ime ne postoji u sistemu)	Dodavanje korisnika koji ne postoji
testRegisterFuncFalse()	Popunjena forma za registraciju (kor. ime postoji u sistemu)	Dodavanje korisnika koji ne postoji
testPostNumQue()	Upisuje se u bazu broj pitanja	Dodavanje broja pitanja na server
testPostScoreTrue()	Popunjeno kor. ime korisnika i rezultat koji se dodeljuje	Upisivanje rezultata korisniku
testGetScoreFunc()	Popunjeno ime korisnika kome znamo da ima neki rezultat	Dohvatanje rezultata korisnika
testReturnQuestionsTrue()	Popunjeno korisničko ime	Dohvatanje broja pitanja
testReturnsData()	Popunjeno pogrešno korisničko ime	Dohvatanje pitanja za korisnika koji ne postoji
testThatViewLoads()	Dohvata se korisnički prikaz	Da li se prikaz dobro instancirao
testThatTableViewLoads()	Dohvata se korisnički prikaz iz memorije	Da li je prikaz tabela dobro učitan
testThatViewConformsToUITableViewDataSource()	Dohvata se DataSource tabele	Da li je DataSource povezan
testThatViewConformsToUITableViewDelegate()	Dohvata se Delegat tabele	Da li je delegat povezan
testNumOfCells()	Dohvataju se pitanja za korisnika sa servera	Da li je broj ćelija jednak broju pitanja

TABELA III
PRIKAZ REALIZOVANIH UI TESTOVA

Funkcionalnost	Stanje u sistemu	Šta testiramo
testLoginOrRegister()	Aplikacija startovana	Pojavljivanje login forme i forme za registraciju
testRegister()	Uneto korisničko ime koje ne postoji u bazi	Da li je moguće registrovati novog korisnika
testLogin()	Uneti su podaci korisnika koji postoji u bazi	Da li je moguće ulogovati korisnika
testLogout()	Ulogovan korisnik ima link da se izloguje iz sistema	Da li je moguće izlogovati se
testFinalScreen()	Na korisničkoj strani klikne se na link za kraj rada	Da li radi navigacija do finalnog prikaza
testNavigationLeftAtLoginAsAdmin()	Korisnik ulogovan kao administrator	Da li je moguće pristupiti svim administratorskim funkcionalnostima
testLoginAsAdmin()	Korisnik pokušava da se uloguje kao administrator	Da li vidi administratorski navigacioni meni
testAddQuestionTitleFalse()	Prazan tekst pitanja	Da li je moguće poslati u bazu pitanje bez teksta
testAddQuestionCorrectAnswerFalse()	Prazno polje za tačan odgovor	Da li je moguće poslati u bazu pitanje bez odgovora
testAddOpenQuestion()	Upisan tekst pitanja, tačan odgovor i izabran tip “open question”	Da li se pitanje sa odgovorom korektno šalje na server i upisuje u bazu
testAddCheckBoxQuestion()	Upisan tekst pitanja, tačan odgovor i tačno tri ponuđena odgovora kod checkbox tipa	Da li se pitanje tipa checkbox uspešno šalje na server i upisuje u bazu
testAddCheckBoxQuestionFalse()	Upisan tekst pitanja, tačan odgovor i manje od tri ponuđena odgovora	Da li je moguće poslati pitanje bez 3 ponuđena odgovora

testAddDateQuestion()	Upisan tekst pitanja, tačan odgovor i izabran "date question"	Da li se pri pravilno unetim podacima pitanje šalje serveru i upisuje u bazu
testAddUser()	Upisano korisničko ime, lozinka i adresa e-pošte korisnika koji ne postoji	Da li je moguće da administrator u bazu doda korisnika koji ne postoji
testAddUserFails()	Upisano korisničko ime, lozinka i adresa e-pošte korisnika koji postoji	Da li je moguće da administrator u bazu doda korisnika koji postoji
testGetScore()	Upisano korisničko ime korisnika koji postoji	Pokušava se dohvatiti rezultat korisnika koji postoji
testGetScoreFails()	Upisano korisničko ime korisnika koji ne postoji	Pokušava se dohvatiti rezultat korisnika koji ne postoji
testAddNumQuestions()	Upisuje se broj pitanja po kvizu	Testira se da li administrator može da unese broj pitanja

Fajl u kome pišemo UI test treba da učita *XCTest* okvir. Klasa koja vrši testiranje izvedena je iz klase *XCTestCase* i ona instancira objekat klase *XCUIApplication*, koji treba da pristupi elementima aplikacije. Pristupanje se vrši tako što objekat identifikuje aplikaciju navedenu kao atribut *target*. Klasa preklapa dve funkcije: *setUp()* i *tearDown()*. Funkcija *setUp()* se izvršava uvek na početku testa i u njenom telu se prvo poziva *setUp()* funkcija natklase. Ukoliko napišemo promenljivu *continueAfterFailure* i postavimo je na vrednost *false*, to znači da se testiranje ne nastavlja, ako ovaj test padne. Nakon ove funkcije, vrši se pokretanje aplikacije i izvršavanje testa. Kada test krene svoje izvršavanje, od prvog elementa nastaje stablo, koje se dalje gradi, počevši od korenog čvora – *Application* objekta, pa dalje ka listovima. Na kraju svakog testa pokreće se funkcija *tearDown()* koja gasi aplikaciju. U listingu 1 prikazan je inicijalni sadržaj testa.

```
class quizAppUITests : XCTestCase {
  let app = XCUIApplication()
  override func setUp() {
    super.setUp()
    continueAfterFailure = false
    XCUIApplication().launch()
  }
  override func tearDown() {
    super.tearDown()
  }
```

Listing 1. Inicijalni sadržaj UI testa.

Za razliku od *JUnit*-a i sličnih okruženja za pisanje jediničnih testova, u *XCUnit*-u svaka funkcija koja je test funkcija mora započeti rezervisanom reči *test*, a u okviru nje se mogu pozivati ostale funkcije. Dugmadima se pristupa prema dodeljenom imenu. Kada se dohvate i smeste u lokalne promenljive može da se proveri da li je njihov atribut *title* korektan. Takođe, može se ispitati postojanje određenog elementa korišćenjem *exists*.

Navigacija se testira tako što se odabere dugme za logovanje ili registrovanje novog korisnika pozivom funkcije *tap()* nad jednim od ta dva dugmeta. Nakon toga treba verifikovati postojanje prikaza ekrana za logovanje ili registraciju. Instanca *let window = app.children (matching: .window).element(boundBy: 0)* vraća prvi iz niza prozora u *iOS* sistemu. Prvi je uvek onaj koji je trenutno aktivan. Konstanta *let element = window. children(matching: .other).element. children(matching: .other).element* se inicijalizuje tako što se pozivaju deca *window* promenljive koja su tipa *.other* i dohvataju se njihovi elementi. Zatim se ponovi radnja i dohvate se svi elementi koji se trenutno prikazuju. Oni se instanciraju preko indeksa, na primer: *XCTAssertTrue (element.children (matching: .textField). element(boundBy: 0).exists).* Na ovaj način je verifikovano da postoji *textField* na ekranu za registraciju. U listingu 2 prikazan je primer testa prvog ekrana u aplikaciji kviz.

```
func loginOrRegistersFunc(){
  let registerButton = app.buttons["Register"]
  let loginButton = app.buttons["Login"]
  XCTAssertTrue(app.staticTexts["Login or
  Register"].exists)
  XCTAssertTrue(registerButton.exists)
  XCTAssertTrue(loginButton.exists)
  XCTAssertEqual("Login", loginButton.title)
  XCTAssertEqual("Register",
                 registerButton.title)
  XCTAssertNotEqual("Register",
                    loginButton.title)
}
func testLoginOrRegister() {
  self.loginOrRegistersFunc()
}
```

Listing 2. Primer testa za dugmad na prvom korisničkom ekranu.

U ovoj mobilnoj aplikaciji očekujemo pitanja iz baze koja se nalazi na serveru, pa iz tog razloga moramo da se povežemo na server i prihvatimo podatke sa servera na klijentskoj strani. Kada se dobiju podaci, proverava se da li su različiti od *nil* pomoću metode *waitForExpectations*. Testirano je da li se dobijaju validni podaci sa servera, odnosno da li pri logovanju za korisnika čiji su kredencijali u redu, dobijen očekivan rezultat, a realizovani su i testovi za logovanje korisnika sa pogrešnom lozinkom i korisnika čije korisničko ime ne postoji. Slično je urađeno i kod registracije novog korisnika.

Realizovan je i jedan broj testova performansi servera i mreže. Ovo testiranje se koristi da se izmeri koliko je vremena potrebno da se izvrši neka funkcija u kodu. U listingu 3 dat je primer testova performansi. Prikazano je kako se testira vreme koje je potrebno da se dohvate podaci o korisniku i njegov rezultat iz baze i koliko je potrebno da se dohvati jedno pitanje iz baze. Izlazni kod ovih testova dat je u listingu 4. Realizovana je i funkcija za dohvatanje svih pitanja iz baze. Test za dohvatanje jednog pitanja prolazi za 0.256 sekundi, a test za dohvatanje svih 80 pitanja za 0.277 sekundi.

```
func testPerformanceScore() {
self.measure{
   ProxyInterface.sharedInstance.scoreFunc
   ("drasko", password: "sifra123",
     completion:{(retVal) -> Void in
})}}

func testPerformanceGetQuestionsOne() {
  UserDefaultsHelper().writeUserDefaults(string: "70")
   self.measure {
      ProxyInterface.sharedInstance.
      getQuestions(completion:{(retVal) -> Void in
          let _ = Questions().parsingQue(getQuestions:
                                         retVal).count
})}}
```

Listing 3. Testovi performansi.

```
Test Case '-[quazzAppTests.TestNetworkingClass
testPerformanceGetQuestionsAll]' passed (0.277
seconds).

Test Case '-[quazzAppTests.TestNetworkingClass
testPerformanceGetQuestionsOne]' passed (0.256
seconds).

Test Case '-[quazzAppTests.TestNetworkingClass
testPerformanceScore]' passed (0.260 seconds).
```

Listing 4. Izlazni kod testiranja performansi.

Pokrivenost koda realizovanim jediničnim testovima je 68.85 %, a pokrivenost koda UI testovima je 75.02 %. Ovo se smatra srednjom ka visokoj pokrivenosti koda [8-10].

VI. Zaključak

U ovom radu prikazan je razvoj jedne mobilne aplikacije i način pisanja testova tokom razvoja. Aplikacija je razvijana sa trojslojnom arhitekturom i ima klijentski deo za korisnike, serverski deo sa logikom aplikacije i sloj podataka.

Veliki broj naučnih radova i istraživanja ističe benefit TDD pristupa. Takođe, mnoge organizacije su radile istraživanja u kojima se pokazuje merljivost softverskih bagova kada se koristi TDD u razvoju softveru i kada se ne koristi taj pristup. TDD se može koristiti kako u tradicionalnim metodologijama razvoja softvera, poput vodopada i V-modela, tako i u agilnim metodologijama [11].

U ovom istraživanju pokazano je da i kod jednostavne mobilne aplikacije sa svega nekoliko funkcionalnosti, pristup pisanja jediničnih testova i testova korisničkog interfejsa može da ubrza implementaciju i stavljanje aplikacije u produkciju, sa dosta visokim stepenom pokrivenosti koda.

Zahvalnica

Ovaj rad je delimično bio finansiran od strane Ministarstva prosvete, nauke i tehnološkog razvoja Republike Srbije i projekta TR 32047.

Abstract

This paper describes the implementation of the mobile Quiz application for the iOS platform with the emphasis on software testing process. The application is designed using Model View Controller (MVC) pattern. During the development of the application, the Test Driven Development (TDD) methodology was applied and the XCTest environment was used. Development of tests during implementation phase is a very important process for software engineers, and it raises the quality of the software and reduces the deficiencies in the software. Unit tests for testing the business logic of the mobile application and unit tests for testing the user interface were realized. The coverage of the code by realized unit tests is 68.85%, and the coverage of code by realized user interface tests is 75.02%.

Test Driven Development of Mobile Application using XCTest framework

Automatsko generisanje testova za automotive sisteme zasnovane na AUTOSAR modelu

Aleksandar Lukić, Dragan Kukolj, Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Velibor Ilić, Istraživačko-razvojni Institut RT-RK, Novi Sad, Srbija, Milena Milošević, Fakultet tehničkih nauka, Univerzitet u Novom Sadu

***Apstrakt*– U radu je opisan postupak generisanja testova pomoću kojih se proverava da li se *RTE* (*runtime environment*) sprege izvršavaju kako je predviđeno na ugrađenoj (eng. *embedded*) *automotive* platformi za konkretne namenske kontrolne jedinice (eng. *ECU - Electronic Control Unit*). Predstavljen je jedan od načina za automatsko generisanje testova pomoću kojih se proverava rad softverskih komponenti koje pripadaju *AUTOSAR* modelu. Opisani su procesi od izvlačenja informacija potrebnih za pravljenje testova do samog izvršavanja testa. Za potrebe testiranja su implementirana dva moda, *FreedomFromInterference* i *MiddlewareConnections*. Za proveru funkcionalosti korištena je *Autonomus driving* platforma sa dva domaćina (eng. *host*) i VN89000 uređaj na kome je realizovan *framework* za komunikaciju između namenskog sistema i testnog računara uz pomoć *ethernet* veze.**

***Ključne reči–Automotive*; *AUTOSAR*; Communication; Testing; *RTE*;**

I. Uvod

Automotive inženjering je deo inženjeringa za vozila, koji osim razvoja vozila za drumski saobraćaj ima i primenu u vazdušno-kosmičkim i vodenim vozilima. Ova vrsta inženjeringa se bavi mehaničkim, električnim, elektronskim, programskim i bezbednosnim elementima na osnovu kojih se dizajniraju i projektuju motocikli, automobili, kamioni i slična vozila. Kreiranje, razvoj i proizvodnja su glavne funkcije ove grane nauke.

Tokom istorije prevozna sredstva su se menjala kao i način njihove proizvodnje. Razlika od prvog prevoznog vozila do danas je ogromna i promene su išle u skladu sa razvojem tehnologije i potrebama ljudi. Menjana je veličina automobila, izgled, pogonsko sredstvo, snaga, elektronika, razni dodaci i pomagala radi efikasnije kontrole i upotrebe vozila. Sve to je dovelo do toga da su vozila danas znatno kompleksnija, a samim tim i njihova izrada.

Tako da danas automobili sadrže različite aplikacije kojima je potrebno kontrolisati tok izvršavanja i životni ciklus. Upravljanje njima je komplikovan zadatak i u autoindustriji nema mnogo opcija za ovaj izazov.

Trenutno najbolje i rešenje koje se najčešće koristi proizvela je organizacija *AUTOSAR* (*Automotive Open System Architecture*). Ova organizacija, koju čine partnerska grupa proizvođača automobila i automobilske opreme, se bavi standardizacijom platforme za razvoj softvera za *automotive* industriju.

U samom automobilu se nalaze mnogobrojne elektronske kontrolne jedinice na kojima se izvršavaju softverske komponete koje se ugrađuju da bi se smanjio prostor za grešku u samom radu automobila. Zbog toga je potrebno testirati i proveriti funkcionalnost ovog složenog sistema različitim testovima kako bi se te greške mogle na vreme detektovati i ispraviti.

U ovom radu prikazano je jedno rešenje koje automatsko generiše testove za *AUTOSAR* model kojim se proverava funkcionalnost sistema. Pod automatskim testiranjem podrazumevamo da se sam rad komponente simulira i izvršava automatski, a ne da se deo koji se testira kontroliše ručno, korak po korak i samim tim automatsko testiranje je mnogo brže od ručnog testiranja. Opisane su osnove *AUTOSAR* standarda, izvršno okruženje i testiranje sprega. Dat je pregled operacija kroz koje je potrebno proći da bi generisali i izvršili testove, i prikazana je realizacija tih operacija (raščlanjivanje modela, generisanje potrebnih informacija, izvršavanje), i na kraju se nalazi zaključak.

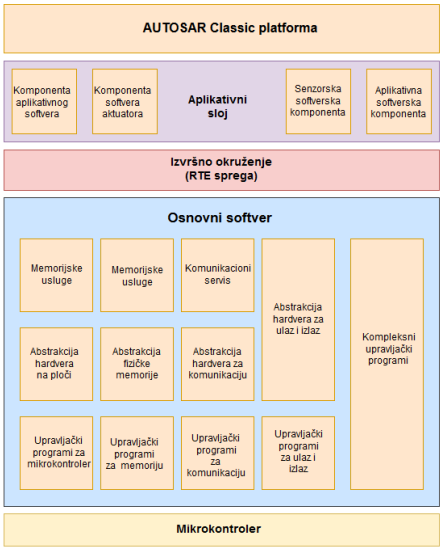
II. Teorijske osnove

U ovom poglavlju je definisano šta znače *AUTOSAR* platforma, izvršno okruženje (eng. *RTE – runtime environment*) i testiranje sprega *(*eng. *Interface testing*). Pomoću ovih osnova razumevanje rada će biti lakše.

A. AUTOSAR platforme

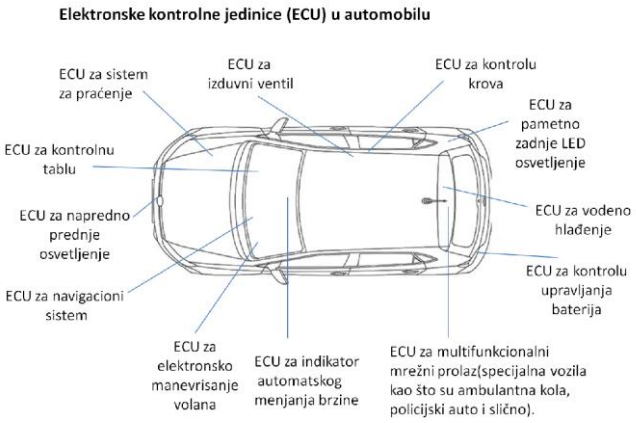
AUTOSAR je grupa osnovana 2003. godine koju danas čine proizvođači automobila, automobilske opreme, proizvođači alata i proizvođači poluprovodnika. *AUTOSAR* grupa je razvila standard koji je jedan od vodećih u automobilskoj industriji za razvoj softvera[1]. Postoje dve softverske platforme *Classic* i

Adaptive. *Classic* je u široj upotrebi i koristi se uglavnom za namenske *ECU* jedinice, dok se *Adaptive* platforma bazira za razvoj aplikacija kojima je potrebnija veća snaga i moć računarske obrade. *AUTOSAR Classic* omogućuje komunikaciju unutar elektronskih kontrolnih jedinica kao i između više njih.



Sl. 1. *AUTOSAR Classic Platform* arhitektura

Arhitektura prikazana na Sl. 1 raspoznaje tri softverska sloja koja se pokreću na mikrokontroleru, a ta tri sloja su aplikativni, *RTE* sprega i osnovni softver. Jedna od osnovnih i najbitnijih delova ove platforme je *VFB* (eng. *Virtual Functional Bus*) [2]. Ova virtuelna magistrala je skup *RTE* sprega koje još nisu raspoređene konkretnoj elektronskoj kontrolnoj jedinici[3]. *VFB* upravlja komunikacijom *ECU* jedinica sa drugim *ECU* jedinicama[4]. Na Sl. 2 se mogu videti neki primeri *ECU* jedinica u automobilu. Ova komunikacija se odvija preko namenskih priključaka (eng. *port*), tako da komunikacione sprege moraju biti povezane sa tim priključcima.

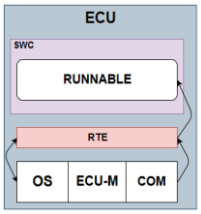


Sl. 2. Primer ECU jedinica u automobilu

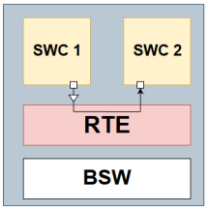
B. *Izvršno okruženje (RTE – runtime environment)*

U *AUTOSAR* arhitekturi *RTE* sprega realizuje komunikaciju između softverskih komponenti (eng. *SWC – Software Component*) i osnovnog softvera (eng. *BSW – Basic Software Component*).

Softverske komponente komuniciraju sa drugim komponentama i/ili modulima osnovnog softvera isključivo preko *RTE* sprega, što omogućava da softverske komponente budu međusobno nezavisne, ali i nezavisne od pojedinačnih *ECU* jedinica. *RTE* sprega predstavlja jednu *ECU* jedinicu i generiše se posebno za svaku konfiguraciju *ECU* jedinice. Svaka particija ili jezgro *ECU* jedinice generiše jednu *RTE* spregu [5]. *RTE* predstavlja apstrakciju operativnog sistema, servisa za komunikaciju, hardverske sprege i planiranje rada softverskih komponenti kao što se može videti na Sl. 3 i 4.



Sl. 3. *RTE* za *runnable* komponentu



Sl. 4. *RTE* kao komunikaciona sprega

Postoje dve vrste komunikacije koje *RTE* realizuje. To su Klijent/Server komunikacija i Pošiljaoc/Prijemnik (eng. *producer/receiver*) komunikacija, a ona se deli na:

- direktno (*Rte_Read*, *Rte_Write*).
- indirektno (*Rte_IRead*, *Rte_IWrite*, *Rte_IwriteRef*).
- redno (*Rte_Receive*, *Rte_Send*).

Pošiljaoc/Prijemnik komunikacija poseduje dva moda: eksplicitni (koristi eskplicitne *RTE API* (eng. *application programming interface*) pozive kako bi primio i poslao delove podataka) i implicitni (*RTE* automatski čita određene setove podataka pre nego što se *runnable* komponenta pozove). Klijent/Server komunikacija takođe poseduje dva moda: sinhroni (rade u istom kontekstu) i asinhroni (rade u različitim kontekstima).

C. *Testiranje sprega (Interface testing)*

Testiranje sprega služi kako bi se izvršila provera da li u sistemu koji proveravamo, njene komponente vrše pravilan prenos podataka između softverskih komponenti, ali i proveru ispravnosti tih podataka kada dođe do izmena nad njima. Ovo testiranje proverava da li interakcija odnosno komunikacija između njih funkcioniše kako treba[6,7]. To nije jedini način da proverimo funkcionalnost softverskih komponenti, postoje i drugi tipovi testova koji proveravaju različite funkcionalnosti. U ovom radu ovo testiranje se izvršava u dva moda koja su delimično modifikovana u ovom rešenju:

- *FreedomFromInterference* (*FFI*) – proveravamo da li su sve veze koje su opisane kroz model prenesene i u sam sistem.
- *MiddlewareConnections* (*MDWConn*) – proveravamo da li se pri svakom pozivu unutar jedne instance statičke planer (eng. *scheduler*) tabele koja se ponavlja, prenos podataka za datu spregu (eng. *interface*) uspešno obavlja.

III. Koncept rešenja

U datom rešenju korišten je jedan sistem za autonomnu vožnju (eng. *Autonomus driving system*) koji je opisan *AUTOSAR* modelom koji je opisan u *.rxml* formatu. Iz sistema za autonomnu vožnju koji testiramo izvučene su potrebne informacije za testiranje željenih softverskih komponenti koje su takođe definisane u modelu. Te komponente smo popunili sa testnim kodom koji predstavlja jedan *framework* koji omogućava kontrolisano izvršavanje testova (*FFI* i *MDWConn*) za svaku *RTE* spregu u sistemu. Kontrolu izvršavanja testnog koda vršimo kroz *framework* na testnom računaru. *Framework* je implementiran kroz *CAPL* (eng. *Communication Access Programming Language*) kod koji se izvršava u kontekstu *Vector CANoe* alata. Ono se oslanja na mrežni interakcioni sloj (eng. *Ethernet Interaction Layer*) koji pruža *CANoe* alat, za slanje i primanje kontrolnih poruka sa namenskih (eng. *embedded*) sistema kao i modul za izveštaje koji nam prikazuje rezultate testova. Glavni zadatak ovog *framework* koda je da kreiranjem odgovarajućih komandnih poruka i tumačenjem odgovara sa testnog sistema kontroliše izvršavanje testova i prikazivanje rezultata testova kroz izveštaj, koji je u *html* formatu[8]. Ovo je sve uspešno odrađeno kroz tri glavne operacije:

- raščlanivanje modela,
- generisanje potrebnih informacija,
- izvršavanje.

IV. Opis realizacije

Aplikacija je izrađena u *Microsoft Visual Studio Community*. Cilj ove aplikacije je da se raščlanjivanjem *AUTOSAR* modela dobiju neophodne informacije kako bi se generisali testovi i neophodni ulazi za *framework* kako bi se testovi izvršili. Samo raščlanjivanje *AUTOSAR* modela odrađeno je pomoću *TinyXML2 XML* [9] raščlanjivača (eng. *parser*) za C++ programski jezik. Ovaj raščlanjivač je izabran zbog toga što je jednostavan za upotrebu i može da obradi veće količine podataka.

A. *Raščlanjivanje modela*

Prvi korak je raščlanivanje *AUTOSAR* modela odnosno *.rxml* datoteke koja sadrži njegov opis. Jedna datoteka predstavlja jedan računar (eng. *host*). Nakon raščlanjivanja dobija se informacija o svim *SWC* jedinicama za dati *host*, o *runnable* komponentama koje su vezane za date *SWC* kao i *RTE* sprege dostupne datoj *runnable* komponenti. Na osnovu ovih informacija pravi se jedna baza podataka koja sadrži veze ovih komponenti koje su potrebne kasnije prilikom generisanja testova odnosno proizvođač/potrošač (eng. *producer*/*consumer*) veza. Na Sl. 5 ovaj korak je predstavljen sa prva dva bloka i dobijene informacije su označene većim sivim blokom.

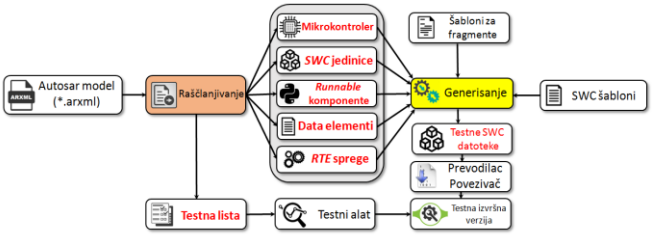
B. *Generisanje potrebnih informacija*

Ulazni podaci za generisanje su baza podataka dobijena parsiranjem, šabloni koji su prethodno generisani od strane *Vector* alata i fragmenti koda koje smo mi kreirali. Ove informacije prikazane su na Sl. 5 kao blokovi koji pokazuju na žuti blok koji obeležava generisanje podataka.

Fragmenti sadrže kod koji će vršiti testiranje *RTE* apstrakcije na sistemu i mogu se generisati sledeće sekcije u *SWC* jedinici:

- ***INCLUDE*** – sekcija u kojoj se definišu promenljive neophodne za kontrolu izvršavanja testova i prenos podataka preko date *RTE* sprege i uključivanje potrebnih zaglavlja.
- ***INIT*** - sekcija koja će biti generisana u inicijalnom delu *runnable* komponente date *SWC* jedinice.
- ***MAIN*** – deo koji će se generisati u cikličnoj *runnable* komponenti date *SWC* jedinice i koji sadrži glavni deo testa za svaku *RTE* spregu.
- ***FUNCTION*** – sekcija za dodatne funkcije koju je neophodno generisati u okviru pojedinačne *SWC* jedinice.

Svaki fragment može da ima neke ili sve od pomenutih sekcija. Napisani su različiti fragmenti u zavisnosti od tipa *RTE* sprege koju testiraju, opisani u sekciji B poglavlja II. Šablone koji su prethodno automatski izgenerisani na osnovu našeg rešenja, popunjavamo ovim sekcijama na odgovarajuća mesta koja su definisana u samom šablonu. Testni kod kojim smo popunili ove šablone nam omogućava da kontrolišemo koji mod je izabran (*FFI* ili *MDWConn*), izvršavanje testa ukoliko je to zahtevano, kontrolu nad željenom *RTE* spregom, rezultate testa i slanje rezultata testa na testni računar.



Sl. 5. Testno okruženje

Sem testnih *SWC* jedinica generišemo i testnu listu (eng. *Test Case List*). Testna lista služi kao početna tačka *framework* kodu

za izvršavanje testova i proveru dobijenih rezultata. Kontrola testova se vrši kroz specijalne linije u testnoj listi koje konfigurišu sam test. One sadrže sve *SWC* jedinice i njima pripadajuće *runnable* komponente. *Framework* raščlanjuje ove informacije i na osnovu njih pravi testne komande koje, kada se protumače na namenskom sistemu, postavljaju početne uslove za izvršavanje testova u datom modu. Glavni deo testne liste su testovi za pojedinačne *RTE* sprege.

One su generisane kao grupa koju čine - proizvođač (eng. *producer*) sa svim svojim relevantnim potrošačima (eng. *consumer*), napravljene na osnovu istog priključka i strukture podata koji idu kroz *RTE* spregu. Bitno je naglasiti da *RTE* sprege koje predstavljaju proizvođače i *RTE* sprege koje predstavljaju potrošače nisu istog tipa (proizvođači: *write, iwrite, iwriteref, client, send*; potrošači: *read, iread, receive, server*), ali imaju zajednički priključak za komunikaciju i strukturu podataka (eng. *data element*) koji se prenose kroz spregu.

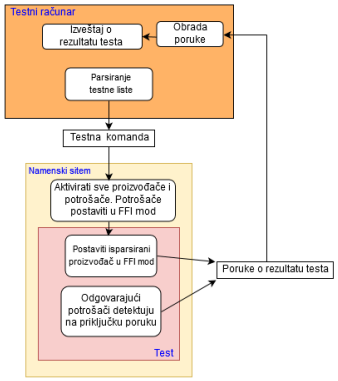
C. *Izvršavanje*

Nakon što su generisane testne *SWC* datoteke i testna lista, spremno je testno okruženje. Da bi se ovo okruženje koristilo za testiranje potrebno je da se izgenerisani kod prevede, uveže (eng. *linking*) i spusti na namenski sistem. Sl. 5 pokazuje tok ovih operacija koji počinje od blokova *Parsing* i *Generate*.

Nakon što se prebaci kod na namenski sistem i ostvari fizička gigabit *ethernet* veza između testnog računara i namenskog sistema, ostaje da se podesi mod izvršavanja testova u konfiguracionoj datoteci i da se pokrene *CANoe* alat sa unapred kreiranom konfiguracijom koja sadrži naš *framework* i da se počne sa izvršavanjem testova[10]. Implementirani *framework* će da izvrši raščlanjivanje testne liste, napraviće komandne poruke i poslati ih na namenski sistem. Nakon što se na namenskom sistemu izvrše testovi aktivirani komandnim porukama, vratiće nazad odgovor i *framework* će da protumači te odgovore i sastaviti izveštaj o uspešnosti izvršavanja testa. Same informacije koje se nalaze u tom izveštaju zavisiće od moda u kojem su se testovi izvršavali.

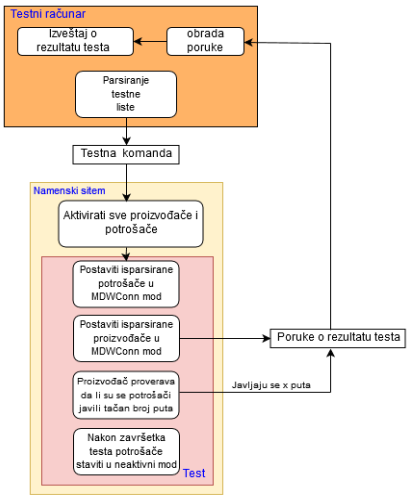
U *FreedomFromInterference* modu želimo da proverimo da su napravljene veze dobro prenesene iz modela koji opisuje realan sistem. U konfiguracionom delu (*startMeasure*) sve *RTE* sprege koje predstavljaju potrošače aktiviramo. To znači da će se u svakoj iteraciji izvršavanja bilo koje *runnable* komponente sve sprege koje su potrošači aktivirati i proveriti ispravnost podataka koji su oni pročitali. Zatim se pojedinačno aktiviraju proizvođači koji su upisani u testnoj listi. Pod aktiviranjem podrazumevamo da se podaci prvo modifikuju korišćenjem algoritma koji je poznat i potrošačima i proizvođačima, a zatim upišu u datu *RTE* spregu. Nakon ovoga *framework* čeka odgovore od potrošačke strane. *Framework* zna uz pomoć testne liste koji potrošač treba da se javi. Sam testni kod na potrošačkoj strani je napisan tako da će se ukoliko se nešto pročita na datoj *RTE* sprezi proveriti da li su pročitani podaci u skladu sa algoritmom promene podataka definisanim za naše testove i zatim se šalje poruka o ispravnosti podataka. *Framework* treba da primi odgovarajući broj poruka, po jednu od svakog definisanog potrošača i samo od njih, sa statusom da su pročitani očekivani podaci.

Ukoliko se to i desi smatra se da je test za datu *RTE* spregu prošao. Na Sl. 6 je prikazan pojednostavljen tok samog testa u ovom modu.



Sl. 6. Tok testa u *FFI* modu

U *MDWConn* modu proveravamo da li se za svaki poziv unutar jedne instance statičke planer tabele, koja se ponavlja, podaci uspešno prenose za datu spregu, kao što je prikazano na Sl. 7. Cilj nam je da proverimo da planer *SWC* jedinice koju testiramo bude ispoštovan, odnosno da su periodi pozivanja proizvođačke *runnable* komponente, potrošačke *runnable* komponente i *middleware runnable* komponente tačni i da će svaki poziv date *RTE* sprege u okviru jednog perioda (eng. *hyperperiod*) biti odrađen kako treba. Informacije o planeru smo prethodno izvukli iz raščlanjenog modela u kome je za svaku *runnable* komponentu definisan period pozivanja.



Sl. 7. Tok testa u *MDWConn* modu

Razlika u odnosu na *FFI* na samom početku je u tome što ne aktiviramo potrošače u konfiguracionom delu već kad započnemo testiranje. Svi potrošači koji se nalaze u testnoj listi se aktiviraju jedan po jedan, a aktiviranje ima isto značenje kao i u *FFI* modu. Nakon toga se aktiviraju proizvođači. Njihovo aktiviranje u *MWDConn* modu podrazumeva da će pozvati datu *RTE* spregu onoliko puta koliko će se data *runnable* komponenta pozvati u datom periodu (eng. *hyperperiod*). Da bi test bio uspešan potrebno je da potrošači odgovore onoliko puta koliko je proizvođač puta bio aktiviran i da sa sobom nosi status da su dobri podaci pročitani. Na kraju jednog prolaza se deaktiviraju potrošači koji su bili testirani u tom prolazu.

Kada prođu svi slučajevi definisani u testnoj listi dobijamo izveštaj i komunikacija se završava.

V. Zaključak

U okviru rada je prikazano jedno rešenje koje pokazuje kako je moguće automatski generisati testove koji proveravaju rad različitih softverskih komponenti koje su deo *AUTOSAR* modela. Odrađen je ceo proces od izvlačenja samih informacija potrebnih za pravljenje testa do samog izvršavanja testa. Kreirani testovi se karakterišu kao integracioni sprežni testovi i napisani su na osnovu *AUTOSAR* specifikacije. Testovi obuhvataju sve moguće slučajeve, jer uzimamo sve sprege iz modela prilikom raščlanjivanja modela. Za potrebene našeg testiranja mi smo implementirali dva moda, *FreedomFromInterference* i *MiddlewareConnections*. Za proveru funkcionalosti ovog rešenja korištena je *Autonomus driving platforma* sa dva domaćina i VN89000 uređaj [11] koji je realizovao *framework* komunikacije između namenskog sistema i testnog računara uz pomoć *ethernet* veze. Rešenje je moguće proširiti tako da je testiranje opširnije, da se proverava više uslova, da se izvršavaju detaljnije provere i analize u samom testu prilikom njegovog izvršavanja ili uz konkretnije modifikacije čak i raščlaniti drugi model.

ZAHVALNICA

Ovaj rad je delimicno finansiran od strane Ministarstva za nauku i tehnologiju Republike Srbije, na projektu tehnoloskog razvoja broj: III44009-6.

ABSTRACT

In this paper it is described procedure of generating tests wich are checking if *RTE* connections are working as intended on embedded automotive platform for specific *ECU* components. It is presented one way for automatic generation of tests which are testing the functionality of software components that are part of *AUTOSAR* model. Process of retaining information needed for creating those tests and their use are also described in this paper. For testing purposes two modes were implemented, FreedomFromInterference and MiddlewareConnections. To check functionality of tests Autonomus driving platform with two hosts and VN89000 device, whom provided framework for communication between embedded system and test PC via ethernet, were used.

Automatic generation of tests for automotive systems based on AUTOSAR model

Aleksandar Lukić, Dragan Kukolj, Velibor Ilić, Milena Milošević

Unapređenje programskog prevodioca Clang sa podrškom za standard MISRA/AUTOSAR

Đorđe Milićević, Mirko Brkušanin, Milena Vujošević Janičić, Teodora Novković, Petar Jovanović

Poštovanje standarda kodiranja je posebno važno u automobilskoj industriji jer greške u softveru automobila mogu imati fatalne posledice. U radu je predstavljeno unapređenje programskog prevodioca Kleng (eng. *Clang*) dodavanjem mogućnosti provere ispunjenosti 164 pravila iz standarda MISRA/AUTOSAR. Predstavljeni su opis i struktura standarda AUTOSAR, kompajlerske infrastrukture LLVM i programskog prevodioca Kleng, kao i detalji realizacije i način integrisanja skupa podržanih pravila u prednji deo infrastrukture LLVM. U okviru realizacije, napravljene su različite vrste proširenja leksičkog, sintaksičkog i semantičkog analizatora. Evaluacijom je utvrđeno da realizovane dodatne analize usporavaju proces prevođenja za svega 19,15%, što čini ovu realizaciju izuzetno efikasnom.

***Ključne reči*: verifikacija softvera; AUTOSAR; MISRA; statički analizator; Kleng; LLVM; kompajler.**

I. Uvod

Softver je postao značajan deo svih aspekata naših života. Značajan deo procesa razvoja softvera odnosi se na process utvrđivanja njegove ispravnosti i kvaliteta, odnosno, verifikaciju softvera. Posledice neispravnosti softvera su mnogobrojne i protežu se od lakših, koje predstavljaju osećaj neprijatnosti usled nestabilnosti rada određene aplikacije, preko teških, koje predstavljaju pojavu ogromnih materijalnih gubitaka, pa sve do fatalnih posledica koje uključuju ljudske žrtve. Iako nije moguće napraviti program koji bi potpuno automatski, u konačnom vremenu, koristeći konačne resurse, mogao da utvrdi ispravnost proizvoljnog programa potpuno precizno, to nikako ne znači nepostojanje odgovarajućeg kompromisa [1].

Posebno važnu oblast primene verifikacije softvera predstavlja automobilska industrija, što za posledicu ima postojanje velikog broja standarda koji propisuju odgovarajuća pravila kodiranja (eng. *coding rules*). Jedan od njih je standard AUTOSAR (eng. *Automotive Open System Architecture*) C++ 14 kojim je propisano više stotina pravila kodiranja koja se odnose na programski jezik C++ [2].

U radu je predstavljeno unapređenje programskog prevodioca Kleng (eng. *Clang*) [3] realizacijom skupa leksičkih, sintaksičkih i semantičkih pravila, propisanih od strane standarda AUTOSAR C++ 14. U glavi II predstavljeni su razlozi za nastanak i razvoj pomenutog standarda, brojnost i različite vrste klasifikacija propisanih pravila, postojeći statički analizatori koji imaju podršku za navedeni standard, kao i primer koji daje uvid u izazovnost realizacije statičkog analizatora koji podržava dati standard. Glava III opisuje strukturu projekta LLVM (sa fokusom na prednji deo kompajlera), implementacione detalje podržanih pravila, način upotrebe dijagnostike za prijavljivanje upozorenja, kao i način integrisanja razvijenog analizatora u postojeći kompajler. U glavi IV predstavljeni su rezultati evaluacije, dok je u glavi V izveden zaključak i date su smernice za buduća unapređenja.

II. Standardi AUTOSAR i MISRA

Standard AUTOSAR C++ 14 [2] nastao je usled nedostatka odgovarajućih standarda za programski jezik C++ (verzije 11 i 14) koji bi se primenjivali na sigurnosne (eng. *safety-related*) i kritične (eng. *critical*) sisteme. Standard MISRA (eng. *Motor Industry Software Reliability Association*) C++ 2008 [4] odnosio se na programski jezik C++ (verzija 03), koji je u vremenu razvoja gorepomenutog standarda AUTOSAR, bio već trinaest godina star i nije pokrivao napredne konstrukcije jezika koje su nove verzije C++ standarda donosile sa sobom. Štaviše, standard MISRA u potpunosti je zabranjivao korišćenje dinamičke memorije, dok je upotreba standardnih biblioteka bila nedovoljno dobro pokrivena. Glavni sektor primene standarda AUTOSAR predstavlja automobilska industrija (eng. *automotive*), ali se oblast primene može proširiti i na druge vrste ugrađenih (eng. *embedded*) sistema.

A. Klasifikacije pravila

Standard AUTOSAR C++ 14 (verzija 18-03) propisuje 402 pravila od kojih je deo pravila usvojen iz postojećeg standarda MISRA C++ 2008 (148 pravila, što predstavlja 64% MISRA standarda), deo pravila izveden iz postojećih standarda programskog jezika C++ (195 pravila), a preostala pravila zasnovana su na različitim vrstama istraživačkih radova (57 pravila) [2].

Pravila iz standarda AUTOSAR moguće je klasifikovati na nekoliko načina: prema **nivou važnosti** (eng. *obligation level*), **primenljivosti statičke analize** (eng. *enforcement by static analysis*) i **oblasti primene** (eng. *allocated target*) [2].

Klasifikacija prema nivou važnosti obuhvata podelu pravila na **obavezna** (eng. *required*) i **savetodavna** (eng. *advisory*). Da bi se za neki program moglo reći da ispunjava zahteve standarda AUTOSAR, sva pravila iz skupa obaveznih pravila

moraju biti ispunjena. Iako pravila iz skupa savetodavnih pravila nisu obavezna, to nikako ne znači da se ona mogu ignorisati – naprotiv, poželjno je pridržavati ih se u što većoj meri [2].

Klasifikacija prema primenljivosti statičke analize obuhvata podelu pravila na **automatizovana** (eng. *automated*), **delimično automatizovana** (eng. *partially automated*) i **neautomatizovana** (eng. *non-automated*). Automatizovana pravila predstavljaju skup pravila koje je moguće automatizovati u smislu statičke analize. Delimično automatizovana pravila moguće je automatizovati korišćenjem odgovarajućih heuristika, tako da pokriju najčešće scenarije koji vode ka narušavanju ispravnosti programa. Neautomatizovana pravila nije moguće automatizovati u smislu statičke analize, već zahtevaju ručno analiziranje programa ili korišćenje nekih drugih, dodatnih alata [2].

Klasifikacija prema oblasti primene obuhvata podelu pravila na **implementaciona** (eng. *implementation*), **verifikaciona** (eng. *verification*), **infrastrukturna** (eng. *infrastructure*) i pravila koja se odnose na **iskorišćene alate** (eng. *toolchain*). Implementaciona pravila odnose se na implementaciju projekta, odnosno, programski kôd, softverski dizajn i arhitekturu. Verifikaciona pravila odnose se na verifikacione aktivnosti poput pregleda, analize i testiranja koda. Infrastrukturna pravila odnose se na operativni sistem i hardver, dok se poslednji skup pravila odnosi na iskorišćene alate poput pretprocesora, kompajlera, linkera i biblioteka [2].

B. *Primer neodlučivog pravila*

U skupu pravila koje standard propisuje, postoje pravila koja su po svojoj prirodi neodlučiva (eng. *undecidable*) u opštem slučaju. Svojstvo neodlučivosti sugeriše kompleksnost algoritama koji se koriste pri implementaciji takvih pravila i korišćenje odgovarajućih aproksimacija, koje za posledicu imaju generisanje takozvanih lažnih uzbuna (eng. *false alarm*). U nastavku teksta će na jednom od pravila, koje ne dozvoljava postojanje mrtvog koda (eng. *dead code*), biti prikazana teškoća rezonovanja o tome da li je neki deo koda mrtav, odnosno, da li će neki deo koda biti izvršen u fazi izvršavanja programa. Uzmimo za primer *while* petlju u kojoj se u zavisnosti od uslova određuje dalji tok izvršavanja programa. Ukoliko uslov petlje ne može biti evaluiran u vremenu prevođenja (jer zavisi od okruženja u kojem se dati program izvršava), iz toga sledi da nije moguće sa sigurnošću utvrditi tok kojim će se izvršavanje programa nastaviti, a samim tim ni rezonovati o tome da li je neki deo programa mrtav ili ne. Algoritam, kojim je spomenuto pravilo implementirano, ne bi trebalo da proglasi određeni deo koda mrtvim (ukoliko postoje tendencije da u nekom slučaju taj deo koda bude izvršen), ali takođe broj lažnih uzbuna mora biti sveden na minimum. Iz toga jasno proističe zaključak da su neodlučiva pravila veoma izazovna za implementaciju i testiranje, kao i da se pri njihovoj implementaji moraju koristiti odgovarajuće heuristike i aproksimacije.

III. STATIČKA ANALIZA KODA

Statička analiza koda obuhvata sve tehnike analize karakteristika koda bez njegovog izvršavanja, a koje imaju za cilj pronalaženje defekata u kodu. Statička analiza može biti neautomatizovana, u obliku pregleda koda (eng. *code review*) ili automatizovana. U okviru automatizovane statičke analize vrše se različite provere kvaliteta koda, počevši od izračunavanja mnogobrojnih softverskih metrika do provera ispravnosti koda u kontekstu nepostojanja grešaka u fazi izvršavanja (eng. *runtime error*), kao što su deljenje nulom, pisanje van granica niza (eng. *buffer overflow*), dereferenciranje neispravnog pokazivača, postojanje mrtvog koda i slično. Dok je izračunavanje metrika koda veoma jednostavno, za potrebe statičkih provera koje se odnose na osobine softvera koje se ispoljavaju u fazi izvršavanja, razvijene su kompleksne tehnike apstraktne interpretacije [5] (primeri alata su **Astree** [6], **Coverty** [7], **Polyspace Bug Finder** [8]), proveravanja modela [9] (primeri alata su **CBMC** [10], **LLBMC** [11], **LAV** [12]) i simboličkog izvršavanja [13] (primeri alata su **KLEE** [14] i **PEX** [15]). Osnovne razlike ovih tehnika su u preciznosti i efikasnosti analize koju obavljaju. Pomenute tehnike mogu se koristiti i u okviru provere ispunjenosti kodiranja po standardu AUTOSAR C++ 14.

A. *Statički analizatori za standard C++ 14*

Neki od postojećih statičkih analizatora koda, koji imaju podršku za AUTOSAR C++ 14 standard, su: **Helix QAC** (kompanije Perforce) [16], **Klocwork** (kompanije Rogue Wave) [17] i statički analizator kompanije LDRA [18]. Prema dostupnim informacijama kompanije Rogue Wave, statički analizator Klocwork podržava 181 pravilo iz standarda AUTOSAR C++ 14 (verzija 18-03) [17].

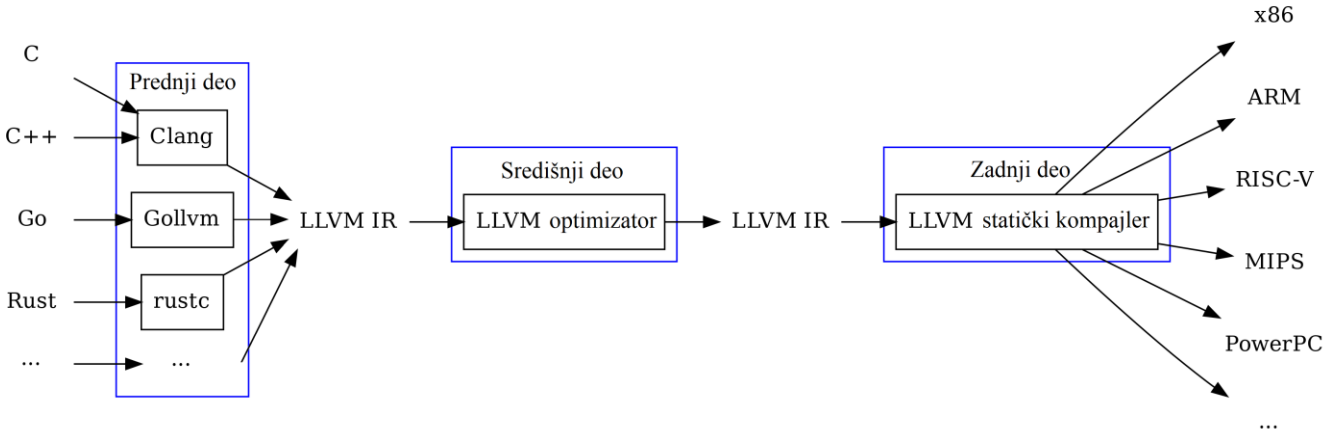
IV. REALIZACIJA

Projekat LLVM [19] sastoji se iz više biblioteka i alata koji zajedno čine veliku kompajlersku infrastrukturu. Osnovna filozofija LLVM-a je da je „svaki deo neka biblioteka" i veliki deo koda je ponovno upotrebljiv. Projekat je započet 2000. godine na univerzitetu u Ilinoisu, kao istraživački rad sa ciljem proučavanja tehnika kompajliranja i kompajlerskih optimizacija [20]. Danas je LLVM prerastao u sveobuhvatni naziv za više projekata koji zajedno čine potpun kompajler: prednji deo (eng. *frontend*), središnji deo (eng. *middleend*), zadnji deo (eng. *backend*), optimizatore, asemblere, linkere, libc++ i druge komponente. Projekat je napisan u programskom jeziku C++, koristeći prednosti objektno-orijentisane paradigme, generičkog programiranja (upotrebom šablona), a takođe sadrži i svoje implementacije raznih struktura podataka koje se javljaju u standardnim bibliotekama programskog jezika C/C++, kao i novu klasu za efikasnije upravljanje niskama karaktera (eng. *string*).

Termin LLVM se nekada može koristiti i sa drugim značenjem. Tako na primer možemo govoriti o kompajleru zasnovanom na LLVM-u, koji može biti u potpunosti ili delimično izgrađen od LLVM strukture. Možemo koristiti prednji i zadnji deo iz LLVM-a, a povezivati (eng. *linking*) sa GCC-om i GNU-ovim bibliotekama.

A. *Struktura LLVM projekta*

Osnovni delovi projekta LLVM su prednji deo, središnji deo i zadnji deo (Sl. 1.) [19]:



Sl. 1 Podela LLVM-a na predni deo, IR (srednji deo) i zadnji deo.

Prednji deo prevodi izvorni kôd (eng. *source code*) nekog od podržanih programskih jezika u međureprezentaciju LLVM IR (eng. *intermediate representation*). Ovaj deo podrazumeva leksički, sintaksički, semantički analizator i generator LLVM međureprezentacije. Kleng je podprojekat LLVM-a koji predstavlja prednji deo za jezike: C, C++ i Objective-C. Pored spomenutog on nudi još i dodatne alate i biblioteke za statičku analizu koda.

IR je programski jezik niskog nivoa, blizak asembleru. IR je jezik u formi SSA (eng. *static single assignment*) koju odlikuje beskonačan broj registara. U **središnjem delu** procesa kompilacije nalazi se veliki broj optimizacionih prolaza. Optimizaciju možemo posmatrati kao prevođenje početnog koda u semantički ekvivalentan, ali efikasniji kôd.

Zadnji deo služi da generiše izvršni kôd za specifičnu arhitekturu. Dobijeni IR će se prevesti u odgovarajuće mašinske instrukcije. Takođe će obaviti i neke dodatne transformacije kao što je registarska alokacija, transformacije petlji i razne druge optimizacije koje su specifične za platformu za koju se prevodi.

Svaku od ovih komponenata moguće je pokrenuti pojedinačno sa ulaznim i izlaznim datotekama odgovarajućeg formata. Ukoliko nam uvid u razne međurezultate nije potreban, a samo želimo da dobijemo izvršnu datoteku, onda za to možemo upotrebiti Kleng. Pored biblioteka za prednji deo on se može koristiti i kao alat koji upravlja celokupnim procesom kompajliranja. Jednostavno će izlaz jedne faze proslediti narednoj i tako ne moramo biti upoznati sa pojedinačnim alatima i njihovim načinom korišćenja. Uz pomoć ovog interfejsa Kleng možemo koristiti kao bilo koji drugi kompajler. Takođe je kompatibilan sa flegovima kompajlera GCC, pa LLVM možemo lako koristiti kao zamenu [19].

Kada se govori o Klengu potrebno je razlikovati rukovaoca (eng. *driver*) koji upravlja procesom kompilacije od prednjeg dela koji se bavi obradom izvornog koda i generisanja IR-a.

B. Implementacija statičke analize

Kako se standardi AUTOSAR i MISRA bave propisivanjem pravila za C++, nama će od značaja biti samo Kleng, odnosno, samo one biblioteke iz prednjeg dela koje direktno zavise od programskog jezika C/C++, a to su: *Lex* (pretprocesiranje i leksička analiza), *Parse* (sintaksička analiza) i *Sema* (semantička analiza). Celokupna implementacija do sada ugrađenih pravila nalazi se u ove tri biblioteke. Projekat je urađen kao nadogradnja LLVM verzije 7.0.1.

Rezultat rada nakon leksičke, sintaksičke i semantičke analize je ispravno apstraktno sintaksičko stablo (eng. AST, *abstract syntax tree*). Ova struktura, iako ne čuva sve detalje sintakse, jasno oslikava strukturu koda i veliki deo detalja, što je čini pogodnijom za dalje ispitivanje i obrade od obične tekstualne reprezentacije. Svaki čvor stabla odgovara jednom konstruktu jezika. Na primer, možemo imati čvor koji odgovara operatoru sabiranja ili množenja. Potomci tog čvora su operandi koji mogu biti konstante, promenljive ili neki drugi složeni izrazi.

Implementacija svakog pravila je enkapsulirana u zasebnu funkciju ili klasu. Izuzeci postoje za vrlo jednostavna i slična pravila kao što su, na primer, zabrana upotrebe pojedinih zaglavlja. Postoje odvojena pravila koja kažu da nije dozvoljno koristiti mogućnosti biblioteka: *csignal*, *cstdio*, *ctime* i *clocale*. Sve četiri provere se razlikuju samo u poređenju sa odgovarajućom niskom karaktera i vrlo ih je prirodno spojiti.

Način prijavljivanja prekršaja nekog pravila vrši se pomoću Klengovih mehanizama dijagnostike. Dovoljno je da znamo lokaciju u kodu gde se javlja element koji ne poštuje standard, kao i naziv upozorenja koji odgovara pravilu koje prijavljujemo. Za svako pravilo postoji zaseban fleg, kao što je *–Wvolatile-keyword-used* (slika 2), koji kontroliše da li će se ono ispitati i prijaviti odgovarajuće upozorenje korisniku. Ukoliko želimo da uključimo sva upozorenja tada, prilikom prevođenja, koristimo opciju *-Wautosar-cxx14*. Takođe su dostupni i flegovi za manje grupe pravila koje odgovaraju podeli iz standarda AUTOSAR (grupa pravila za klase, izraze, deklaracije i sl.). Jednostavnim upitom nad klasom za dijagnostiku možemo proveriti da li je neki od flegova prisutan i tako kontrolisati izvršavanje naših dodatnih provera.

```
test.cpp:9:3: warning: volatile keyword shall not be used
 volatile int i;
 ^
```

Sl. 2 Primer ispisa Klenga za prekršaj pravila.

Trenutna implementacija sadrži 164 pravila, od toga je 50 implementirano kao prosti funkcijski pozivi, 70 kao zasebne klase koje se oslanjaju na neku od pomoćnih struktura iz Klenga, 31 je u potpunosti podržano od strane Klenga kao i 13 koja ne pokrivaju sve slučajeve koje AUTOSAR zahteva i potrebno ih je dopuniti.

Pravila implementirana kao funkcije. Prilikom obrade izvornog koda kroz biblioteke *Lex, Parse* i *Sema* vrše se provere da li je kôd ispravno i smisleno napisan. Ukoliko su korišćene naredbe ili elementi jezika koji ne postoje ili nisu lepo upareni kompajler će nam prijaviti grešku ili upozorenje. Neka od prostojih pravila standarda AUTOSAR i MISRA predstavljaju zabranu upotrebe pojedinih elemenata, struktura ili funkcija iz programskog jezika C++. Prema tome, prirodno je implementirati ih baš na mestu gde se oni obrađuju. Ugrađivanjem dodatnih provera i ograničenja možemo prepoznati situacije koje su nam od značaja. Kako bi što više zadržali nezavisnost originalnog Kleng koda od našeg, sve dodatne provere se vrše u zasebnim funkcijama koje samo pozivamo na odgovarajućim mestima. Tako, na primer, funkcija koja sadrži logiku za pravilo koje ograničava upotrebu ključne reči *typedef* će se pozvati na mestu u parseru neposredno nakon obrade te ključne reči.

Pravila implementirana kao klase. Ukolko je pravilo zahtevnije onda će i logika koja ga opisuje biti složenija pa se ne može efikasno implementirati pomoću obične funkcije. Tu su nam od velike pomoći rekurzivni AST posetioci (eng. *Recursive AST Visitors*). Ova klasa nam nudi mogućnost obilaska celog AST stabla pretragom u dubinu. Za svaki tip čvora u stablu, koji nam je od značaja, možemo definisati odgovarajući metod posete. Potrebno je naslediti klasu *RecursiveASTVisitor* i predefinisati željeni metod. Na primer, ukoliko nas interesuju upotrebe binarnih operatora onda ćemo definisati metod *VisitBinaryOperator(BinaryOperator *)*. Svi metodi posete kao argument dobijaju pokazivač na čvor koji se trenutno obilazi odakle možemo dobiti sve informacije koje nas interesuju. Tako će, na primer, pravilo koje ispituje da li se koriste ispravni operatori nad promeljivama tipa *bool* da poseti čvorove u stablu koji opisuju binarne i unarne operatore. Metod posete će se sastojati od provere da li se koristi neki nedozvoljen operator zajedno sa proverom da li su operandi tipa *bool*.

Pored metoda posete dostupni su nam i metodi obilaska. Njih koristimo kada želimo da obiđemo stablo u dubinu od nekog konkretnog čvora, a možemo ih i predefinisti ako nam je potreban neki drugi redosled obilaska. Najčešće ih koristimo kada želimo da se naše pravilo ispita za celokupni kôd. Potrebo je pozvati već definisani metod obilaska *TraverseDecl(Decl *)* sa korenim čvorom AST-a kao argumentom.

Drugi korisni mehanizam koji koristimo je klasa *PPCallbacks*. Ona predstavlja interfejs za praćenje rada pretprocesora. Za neka pravila koja se odnose na pretprocesorske direktive ne možemo na mestu njihove obrade u biblioteci *Lex* znati da li su ispoštovana ili ne. Jedno od takvih pravila se odnosi na proveru neiskorićenih zaglavlja. To možemo utvrditi tek kada imamo uvid u potpun AST ulaznog koda i znamo da li se neka funkcija, struktura ili bilo koji drugi element deklarisan u nekom od zaglavlja zapravo koristi. Tada ćemo nasleđivanjem klase *PPCallback* i predefinisanjem željenih metoda za obradu „include" direktiva, makroa i drugih elementa sakupiti sve podatke koji će nam biti od koristi. Tek u nekoj kasnijoj fazi kompilacije kada nam budu dostupne preostale informacije o ulaznom kodu zajedno sa podacima iz pretprocesora možemo doneti odluku o traženim pravilima.

Integracija sa Klengom. Sav kôd koji je dodat se nalazi u novim i odvojenim datotekama. Jedine izmene u postojećem kodu su u .cpp datotekama i predstavljaju samo umetnute pozive funkcija zajedno sa uključivanjem neophodnih zaglavlja na odgovarajućem mestima u bibliotekama *Lex*, *Parse* i *Sema*. Te funkcije ili vrše jednostavnu proveru pojedinih pravila ili instanciraju rekurzivne posetioce za obilazak AST-a. Kao argumente, te funkcije uzimaju podatke koji su im dostupni ali ih nikada ne menjaju i time ni na koji način ne utiču na postojeću funkcionalnost Klenga niti je ometaju.

V. Evaluacija

Pored samog broja implementiranih pravila bitna nam je i efikasnost tih provera. Svaka nova provera troši dodatno procesorsko vreme. Pokretanje našeg koda, koji podržava 164 pravila, troši 32,5% više vremena za izgradnju svih testova grupa *SingleSource* i *MultiSource,* dostupnim u okviru LLVM test-suite-a, kada su sve provere uključne. Glavni razlog ovog usporenja je veliki broj prijava pojedinih pravila usled testiranja na kodu koji nije pisan po standardu AUTOSAR ili MISRA. Primer takvog pravila je zabrana upotrebe celobrojnih tipova koji nisu fiksne veličine. Dakle, umesto: short, int, long i dr. potrebno je koristiti tipove int8_t, int16_t, int32_t, int64_t ili njihove ekvivalente bez znaka. Kako je upotreba ovih tipova vrlo česta javlja se i veliki broj upozorenja za ovo pravilo i to čak 18.85% od svih upozorenja. Sledeća mnogobrojna pravila po broju upozorenja su: implicitno umanjanje veličine tipa prilikom konverzije (12,64%), elementi van globalnog namespace-a (8.95%) i tipografski slični identifikatori (7,38%). Preostala pravila daju manje od 5% upozorenja po pravilu.

Kako prijavljivanje velikog broja prekršaja korisniku nije uvek od koristi ugrađena je i mogućnost ograničavanja broja upozorenja po pravilu. Ograničavaljem na 1, 2 ili 5 upozorenja je dovoljno da se korisnik obavesti da kôd nije po standardu i koja su sve pravila prekršena. Zatim se može iterativno popravljati kôd i pokretati jedno po jedno pravilo bez ograničenja. Prilikom ograničenja na maksimalno 5 upozorenja po pravilu vreme potrebno da se prevede ceo LLVM test-suite je 11.2% duže od pokretanja bez ograničenja. Sa samo jednim upozorenjem dobija se sličan rezultat, dok ukoliko isključimo dijagnostiku za prijavljivanje upozorenja kako ne bi računali vreme potrebno za njihov ispis imamo uvećanje od 19,15%. Ova informacija nam bolje oslikava koliko se vremena troši na sam ispis dijagnostike, nasuprot vremenu potrebnom za celokupnu analizu koda našim kompajlerom. Ukoliko pišemo kôd po standardu i redovno vršimo provere možemo očekivati da ćemo imati mali broj upozorenja pa samim tim i manje vreme potrebno da se izvrši celokupna analiza koda sa našim kompajlerom.

VI. ZAKLJUČAK.

U okviru rada prikazano je da se značajan broj pravila može jednostavno i efikasno implementirati u Klengu. Sa novim dopunama, koje nemaju uticaja na već postojeću funkcinalnost, od već kvalitetnog kompajlera dobijamo novi alat sa velikim brojem statičkih analiza koda. Sve dodatne provere se mogu jednostavno (po potrebi) uključiti ili isključiti, pa ne moramo brinuti o tome da će naša verzija na bilo koji način poremetiti ili usporiti podrazumevani način upotrebe Klenga. Kako su sve izmene postojećeg koda minimalne, naša implementacija se može lako nadovezati na buduće verzije.

Sa svakom dodatnom proverom razmenjujemo procesorsko vreme za bezbedniji kôd. Na korisniku ostaje da odluči da li se isplati prosečno povećanje od 19,15% prilikom prevođenja za 164 dodatnih provera. Kako se sva analiza obavlja u prednjem delu, može se pokrenuti i bez potpunog prevođenja. Pametnom upotrebom analizatora sa ograničavanjem broja upozorenja, i samo nad jedinicama prevođenja koje korisnik u tom trenutku razvija, može se značajno uštedeti na vremenu.

A. Moguća unapređenja

Pored dodavanja novih pravila podjednako je važno i umanjivanje broja lažnih upozorenja. Zbog postojanja neodlučivih pravila nije uvek moguće dati precizan odgovor. Međutim, veliki broj lažnih upozorenja može zbuniti korisnika i obeshrabriti ga od upotrebe statičkih analizatora. Zato je testiranje na većim količinama koda i unapređivanje postojeće implementacije od velikog značaja.

ZAHVALNICA

Ovaj rad je delimično finansiran od strane Ministarstva za prosvetu, nauku i tehnološki razvoj Republike Srbije, na projektu brojevi: TR32041 i IO174021.

ABSTRACT

Respecting coding standards is especially important in automotive industry because automotive software bugs can have fatal consequences. The paper presents an improvement of the Clang compiler by adding verification capabilities fulfillment of 164 rules from the MISRA/AUTOSAR coding standard. The paper presents the description and structure of the AUTOSAR coding standard, LLVM compiler infrastructure and Clang compiler, as well as implementation details and how to integrate the set of supported rules in the frontend of the LLVM infrastructure. Within the implementation, different types of extensions have been made to lexical, syntax and semantic analyzers. An evaluation was established that the implemented additional analyzes slow down the process of compilation for only 19.15%, which makes this implementation extremely efficient..

Improving Clang compiler with MISRA/AUTOSAR coding standard support

Dodavanje podrške za arhitekturu nanoMIPS u alat za dinamičku analizu programskog koda Velgrind

Dimitrije Nikolić, Aleksandra Karadžić, Aleksandar Rikalo i Petar Jovanović

***Apstrakt*—Pojava nove arhitekure mikroprocesorkih sistema pored hardverskog čipa podrazumeva i određene softverske alate, poput kompajlera i emulatora. Upotreba nove arhitekture, odnsosno kreiranje složenih aplikacija za novu arhitekturu, povlači potrebu za softverskim alatima koji bi olakšali detektovanje nepravilnog rada programa i lakše pronalaženje grešaka, poput debagera i profajlera. Ovaj rad opisuje izmene koje su potrebne za dodavanje podrške jednom softerskom alatu za analizu programa, Velgrindu, za novu arhitekturu MIPS Techologies grupe – nanoMIPS.**

***Ključne reči*—Velgrind, MIPS, nanoMIPS**

I. Uvod

Traženje razloga nepravilnog rada sistema može potrajati dosta dugo, pogotovu ako se sistem sastoji iz desetina hiljada linija koda i desetine pa i stotine operacija alociranja i dealociranja memorije. Pod ovim podrazumevamo greške koje prevodioci ne prijavljuju, poput curenja memorije ili korišćenja neinicijalizovanog podatka. Za neke još složenije, višenitne sisteme, ove greške se mogu javiti u vidu neočekivanog pristupa deljenim podacima, odnosno utrkivanju za pristup istim. Jedan od alata koji pomažu u otkrivanju ovakvih grešaka jeste Velgrind. Velgrind predstavlja veoma koristan alat, pogodan za analizu svih nivoa memorije. Puštanje programa kroz Velgrind jeste značajno sporije (od 20 do 100 puta sporije), ali sa lakoćom može otkriti nepravilnosti prilikom korišćenja memorije.

Cilj ovog rada jeste omogućiti korisnicima, koji rade na najnovijoj MIPS arhitekturi - nanoMIPS, korišćenje Velgrinda i tako im olakšati razvoj sistema na ovoj arhitekturi. Kako bismo realizovali podršku Velgrind alata za nanoMIPS arhitekture, moramo, pored detaljnog upoznavanja načina rada Velgrinda, izučiti novi instrukcijski set nanoMIPS arhitekture, kao i uporediti novouvedeni ABI p32 sa do sada korišćenim ABI-jem o32, odnosno sličnosti i razlike između ova dva interfejsa.

Petar Jovanović III_044009_1, Naučno istraživački institut RT-RK, Narodnog fronta 23a 21000 Novi Sad, Srbija (telefon: 381-21-480-1193, e-mail: petar.jovanovic@rt-rk.com).

II. Motivacija

Motivacija za pisanje ovog rada je višestruka:

- predstavljanje karakteristika nove arhitekture kompanije MIPS Technologies – nanoMIPS
- predstavljanje načina rada dinamičkog analizatora programskog koda Velgrind
- predstavljanje rešenja za dodavanje podrške nove arhitekture u dinamički analizator programskog koda Velgrind

III. Uvod u Velgrind

Valgrind predstavlja DBI radni okvir za Linuks/x86 platformu. Originalno, Valgrind je dizajniran da bude besplatan alat za detekciju grešaka prilikom korišćenja memorije za Linuks na x86 arhitekturi, ali je vremenom prerastao u okruženje za kreiranje alata za dinamičku binarnu analizu.

Trenutna verzija Velgrinda je 3.14.0 (objavljena 9. oktobra 2018. godine) i ona sadrži sledeće alate:

- *Memcheck* – alat za otkrivanje grešaka prilikom korišćenja memorije, i primarno je namenjen za C/C++ programe.
- *Cachegrind* – alat za profiliranje keš memorije.
- *Callgrind* – proširenje *Cachegrind*-a, može se koristiti za vizuelizaciju podataka dobijenih radom *Cachegrind*-a.
- *Massif* – alat za profiliranje dinamičke memorije (*heap*-a).
- *Helgrind* – alat za otkrivanje utrkivanja niti prilikom pristupa deljenom podatku.
- *DRD* – alat za analizu višenitnih program, koji zauzima mnogo manje memorije od *Helgrind*-a tokom svog rada.
- *Lackey* & *None* (*Nulgrind*)–alati koji postoje za testiranje Velgrinda i demonstrativne svrhe.

Podržane su sledeće arhitekture:

- Linux OS : x86, AMD64, ARM, MIPS32, MIPS64, TILEGX, PPC32, PPC64, PPC64LE, S390X
- Solaris OS: x86, AMD64
- Android OS: ARM (od 2.3.x), ARM64, x86(od 4.0), MIPS32
- Darwin OS: x86, AMD64 (Mac OS X 10.10, sa inicijalnom podrškom za 10.11)

IV. ANALIZA RADA VELGRINDA

Alati za dinamičku analizu koda se kreiraju kao dodatak, pisan u programskom jeziku C, na jezgro Velgrinda. Velgrind se najjednostavnije može predstaviti kao:

Osnova Velgrinda(jezgro+VEX) + dodatak u vidu alata = Velgrind alat

Vex (prevodilac JIT tipa) je zadužen za dinamičko prevođenje koda, dok je jezgro Velgrinda zaduženo za ostatak (raspoređivanje procesa, vođenje računa o deljenoj memoriji, itd.). Programska podrška Velgrinda je logički podeljena na dve suštinski različite celine: *host* (sprega između Velgrindove interne reprezentacije (IR) i ciljne arhitekture) i *guest* (sprega između klijentskog koda i Velgrindove interne reprezentacije).

Velgrind deli klijentski program u sekvence koje se nazivaju bazični blokovi. Bazični blok je deo programskog koda koji nema uskakanja u kod izuzev prve intrukcije i kraja bazičnog bloka i nema u sebi grananja, sem u poslednjoj instrukciji. Pre prve instrukcije bazičnog bloka nalaze se instrukcija/e skoka ili uskakanje/a u kod.[4] Dodatno ograničenje za veličinu bazičnog bloka kod Velgrinda je 60 mašinskih instrukcija. Na procesorima zasnovanim na MIPS arhitekturi, instrukcije skoka i grananja imaju tzv. „odloženo izvršavanje“, što znači da se prilikom njihovog izvršavanja izvršava instrukcija koja se nalazi neposredno iza instrukcije grananja ili skoka. Ukoliko je poslednja (60.) instrukcija bazičnog bloka instrukcija grananja ili skoka, Velgrind učitava i instrukciju koja se nalazi neposredno iza 60. instrukcije bazičnog bloka.

Programski kod svakog programa koji se analizira se ponovo prevodi na zahtev, pojedinačno na nivou bazičnog bloka, neposredno pre samog izvršavanja bazičnog bloka. Svaki IR blok sadrži listu iskaza koje predstavljaju operacije sa bočnim efektima, kao što su upis u registre/memoriju ili smeštanje vrednosti u privremenim promenljivama. Iskazi se sastoje iz izraza bez bočnih efekata, kao što su konstante, čitanje registara, dohvatanje podataka iz memorije, kao i aritmetičke operacije. Uzećemo za primer jednostavan iskaz za skladištenje podataka. On sadrži dva izraza, jedan za smeštanje adrese, a drugi za smeštanje vrednosti. Izrazi, proizvoljno, mogu biti organizovana u kompleksna stabla (IR stablo) ili u linearizovanu strukturu upotrebom iskaza koji među-vrednosti smeštaju u privremene promenljive.

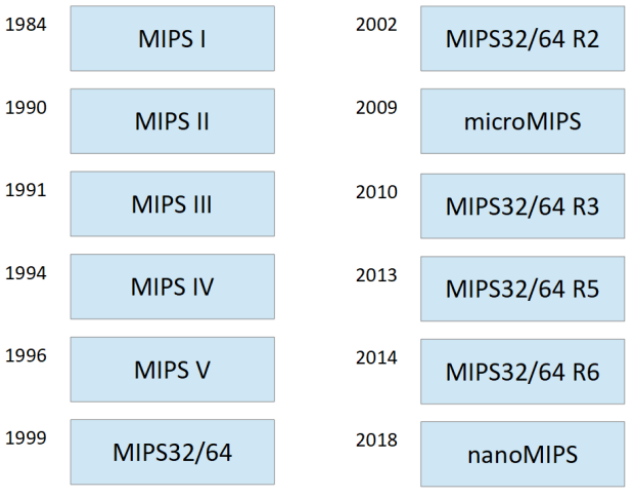
Iako je je ovaj skup primitivnih operacija dovoljan za skoro sve instrukcije, postoje neke instrukcije specifične za neku arhitekturu, koje je nemoguće "razbiti" na više standardnih IR operacija. U tom slučaju se koriste pomoćne funkcije, pisane u programskom jeziku C, koje emuliraju tu instrukciju.

Nakon pokretanja Valgrind-a, započinje translacija, te se kasnije izvršava novodobijeni klijentski program. U toku translacije, mašinski kod se disasemblira u Valgrind-ov međukod, ubacuju se delovi izabranog alata i na kraju asemblira u mašinski kod uz usputne optimizacije. Faza translacije se sastoji iz osam celina:

1. **Disasembliranje** - Disasembler konvertuje mašinski kod u stablo IR-a. Svaka instrukcija mašinskog koda se disasemblira nezavisno u jednu ili više instrukcija IR-a.
2. **Optimizacija IR-a** - Ovaj korak prestavlja prvu od dve optimizacija IR-a koje se rade prilikom translacije. Tokom ovog koraka, kod koji je bio organizovan kao stablo se linearizuje. Iz generisanog IR-a prilikom disasembliranja se uklanjaju redudantne get i put operacije, kao i mrtav kod. Pojednostaljuju se konstantni izrazi i vrši se jednostavno odmotavanje petlji koje se izvršavaju unutar jednog osnovnog bloka.
3. **Instrumentacija** - Instrumentacija ubacuje nove IR instrukcije u kod dobijen u prethodnom koraku. Dodate instrukcije ubacuje odabran alat i one služe za željenu analizu koda. Ove instrukcije ne narušavaju konzistentno izvršavanje originalnog programa. Kako bi se instrumentacija lakše izvršila, važno je da kod u ovom koraku bude linearizovan.
4. **Optimizacija IR-a** - Druga, jednostavnija, optimizacija dodatno pojednostavljuje konstantne izraze i uklanja mrtav kod. Takođe, uklanjaju se i nepotrebne provere definisanosti nastale u prethodnoj fazi. Ova optimizacija „olakšava život" alatu dozvoljavajući mu da uradi nešto na jednostavan način (neoptimizovano) znajući da će taj kod biti naknadno poboljšan.
5. **Gradnja stabla** - U ovom koraku, linearni IR se vraća u reprezentaciju stabla, pripremajući se za narednu fazu.
6. **Odabir instrukcija** - Ovaj korak je zavistan od arhitekture za koju radi Valgrind. Svaka IR instrukcija se prevodi u jednu ili više instrukcija ciljne arhitekture. Tokom ove faze instrukcije i dalje koriste virtuelne (tzv. guest) registre. Selektor instrukcija koristi jednostavan, "pohlepan" algoritam uparivanja stabla koji obrađuje stablo od vrha ka dnu.
7. **Dodela registara** -Virtuelni (guest) registri se zamenjuju registrima ciljne arhitekture (host). U slučaju da broj registra koji su na raspolaganju nije dovoljan, primenjuje se tehnika "presipanja" registra na stek (eng. register spill). Ova tehnika podrazumeva da se svi registri, čije se vrednosti moraju održavati kroz pozive funkcija, privremeno čuvaju na steku. Iako su instrukcije zavisne od arhitekture, alokator registra nije i koristi specifične funkcije da bi zaključio koji se registri koriste (čita ili upisuje u njih) prilikom svake instrukcije.
8. **Asembliranje** - Završna faza translacije, faza asembliranja, jednostavno prevodi odabrane instrukcije u mašinske i upisuje ih u blok memorije.[2]

V. NANOMIPS ARHITEKTURA

Iako trenutno manje zastupljeni, MIPS procesori su imali veliki uticaj na razvoj mikropocesorskih arhitektura. Primera radi, procesor MIPS R4000 je bio prvi mikroprocesor koji je koristio 64-bitnu magistralu podataka, mnogi procesori su se nalazili u ugrađenim sistemima poput Cisco rutera, uređajima za zabavu Sony Playstation, Nintendo, itd. Plod višedecenijskih istraživanja i usavršavanja mikroprocesorskih sistema je hronologijski prikazan na slici 1.



Slika 1 – Istorijat MIPS mikroprocesorskih arhitektura

NanoMIPS je najnoviji 32-bitni instrukcijski skup kompanije MIPS Technologies, objavljen 01. maja 2018. godine. Dizajniran za ugrađene uređaje, nanoMIPS je arhitektura sa promenljivom dužinom instrukcija, pružajući visoke performanse prilikom redukovanja veličine koda. Uz slične flegove kompajleru, nanoMIPS može redukovati veličinu koda do 40% u odnosu na MIPS32. Sa smanjenim brojem pristupa memoriji i efikasnijem korišćenjem instrukcijskog keša, nanoMIPS mikroprocesori takođe redukuju potrošnju snage sistema.

Kao što je već navedeno, nanoMIPS je arhitektura sa promenljivom dužinom instrukcija, dužine 16, 32 ili 48 bitova. Instrukcije dužine 16 bita su zapravo kraće verzije najčešće korišćenih 32-bitnih instrukcija sa ograničenim skupom registra (podskupom od 4, 8 ili 16 registara) koji se mogu koristiti kao operandi. Optimizacijom u kompajleru za nanoMIPS, prilikom dodeljivanja registara instrukcijama, forsiraju se registri iz pomenutih podskupova, te se 16-bitne instrukcije koriste uvek kada za to postoji mogućnost. Takođe, slična optmizacija je implementirana i u linkeru, kome je omogućeno da u objektnom fajlu zameni 32-bitne instrukcije 16-bitnim ekvivalentnim instrukcijama, ako su ispunjeni odgovarajući uslovi (registri prosleđeni kao operandi su deo odgovarajućeg podskupa). Instrukcije dužine 48 bita su novina u odnosu na prethodne MIPS arhitekture i pružaju mogućnost smeštanja 32-bitnog argumenta u samu instrukcijsku reč. Ovom novinom je eliminisana potreba za dodatnom instrukcijom koja bi isti argument smeštala u registar, pre izvršavanja instrukcije kojoj je taj argument potreban.

U zavisnosti od primene i složenosti, određene aplikacije mogu napraviti kompromis tako što će funkcionalnosti instrukcijskog skupa biti ograničene u korist manje "cene" njihove implementacije, odnosno potrošnje memorije i električne energije. Takav kompromis je omogućen postojanjem „nanoMIPS Subset (NMS)" podskupa nanoMIPS instrukcijskom skupa. Tačnije, mikroprocesor može podržati samo određen podskup instrukcijog skupa (NMS), zadržavajući u potpunosti mogućnosti celokupnog instrukcijskog skupa. Ušteda memorije i električne energije se postiže jednostavnijim hardverom koji je neophodan instrukacijama koje čine podskup NMS. [3]

Uz sami instrukcijski set nanoMIPS, razvijan je i novi ABI sa oznakom „p32" kao i konvencija pozivanja potprograma. P32 ABI definiše skup registara od 32 registara opšte namene (GP registri) širine 32 bita ($r0-$r31) i 32 registara sa pokretnim zarezom (FP registri) širine 64 bita ($f0-$f31). Po osam registara od svake grupe se koristi za prenos argumenata potprograma ($r4-$r11, $f0-$f7), dok je kod o32 ABI-ja upola manji. Ostale karakteristike p32 ABI-ja, kao i poređenje sa najzastupljenijim MIPS32 ABI-jem (o32) prikazane su u tabeli 1.

	o32	n32
Korišćen kompajler	gcc/llvm	gcc
Model podataka	ILP32	ILP32
Konvencija poziva potprograma	o32	new
Broj(širina) GP registara	32(32bita)	32(32bita)
Broj GP registara za prosleđivanje argumenata	4($4..$7)	8($r4..$r11)
Broj(širina) FP registara	16/32 (32/64bita)	32(64bita)
Broj FP registara za prosleđivanje argumenata	4	8
Podržani instrukcijski skupovi	mips 1/2	mips 3/4
Poravnjanje steka	8 bajta	16 bajta

Tabela 1 - Poređenje o32 i p32 ABI

Celokupan instrukcijski skup nanoMIPS arhitekture je hijerarhijski podeljen na akumulacije instrukcija (engl. *instruction pools*) na osnovu dužine, odnosno formata instrukcije. Na slici 2 je prikazana akumulacija instrukcija P32 koji sadrži sve 32-bitne instrukcije (kao i akumulacija instrukcija P48I, koji sadrši 48-bitne instrukcije) koji se kasnije dalje dele na osvonu sekvenci bita [31..29,27..26], dok je za sve instrkcije zajednička vrednost bita 28 u instrukcijskoj reči (vrednost nula).

B.2 P32 pool

VI. IMPLEMENTACIJA PODRŠKE VELGRINDU ZA ARHITEKTURU NANOMIPS

S obzirom da je nanoMIPS arhitekura dizajnirana i razvijana "od nule", podrška u Velgrindu je implementirana shodno tome, iako ima dosta sličnosti sa prethodnim arhitekturama MIPS. Implementaciju podrške Velgrindu za nanoMIPS arhitekturu možemo podeliti na nekoliko najbitnijih celina:

- podrška za novi sistemski poziv u Velgrindu - *statx*
- podrška za prevođenje Velgrinda za nanoMIPS
- podrška za disasembliranje nanoMIPS mašinskog koda u (faza 1 rada Velgrinda)
- podrška za asembliranje Velgrindovog IR koda u nanoMIPS mašinski kod (faza 8 rada Velgrinda)

Sistemski poziv *statx* predstavlja noviju verziju sistemskih poziva *stat*, *fstat* i *lstat* (sistemski pozivi za dobijanje informacija o fajlu). Sastavni je deo Linuks operativnog sistema od verzije kernela 4.11, a podržan od strane biblioteka od glibc verzije 2.28.

S obzirom da u listi podržanih sistemskih poziva za arhitekturu nanoMIPS postoji *statx*, sastavni deo podrške za novu arhitekturu jeste i podrška ovog sistemskog poziva u Velgrindu. Implementacija podrške je realizovana emulacijom starijih verzija sistemskih poziva pomoću *statx* sistemskog poziva. Ukoliko sistemski poziv *statx* nije podržan na verziji kernela mašine koja pokreće Velgrind, sistemski poziv *statx* prijavi grešku o nepostojanju sitemskog poziva (*ENOSYS*), pa Velgrind poziva starije verzije ovog sistemskog poziva. Primer prethodno opisanog scenarija, odnosno emulacija sistemskog poziva *stat* pomoću sistemskog poziva *statx* je prikazana na sledećem listingu:

```
SysRes VG_(stat) ( const HChar* file_name, struct vg_stat* vgbuf )
{
   SysRes res;
   VG_(memset)(vgbuf, 0, sizeof(*vgbuf));

+#  if defined(VGO_linux)
+   /* On Linux, first try with statx. If that doesn't work out,
+      fall back to the stat64 or vanilla version. */
+   { struct vki_statx buf;
+     res = VG_(do_syscall5)(__NR_statx, VKI_AT_FDCWD, (UWord)file_name,
+                            0, VKI_STATX_ALL, (UWord)&buf);
+     if (!(sr_isError(res) && sr_Err(res) == VKI_ENOSYS)) {
+        /* Success, or any failure except ENOSYS */
+        if (!sr_isError(res))
+           TRANSLATE_statx_TO_vg_stat(vgbuf, &buf);
+        return res;
+     }
+   }
+#  endif
...
```

Listing 1 - Emulacija sistemskog poziva stat pomoću sistemskog poziv statx

Na osnovu vrednosti atributa --host(nanomipseb-linux-gnu ili nanomips-linux-gnu) prosleđenog prilikom /configure naredbe i izmena u make i configure fajlovima postavljamo određene CPP flegove za primarnu i sekundarnu platformu.

Pre pokretanja Velgrinda, poziva se funkcija sa potpisom static const char* select_platform(const char *clientname) koja određuje platformu za koju treba da se pokrene Velgrind. Rezultat ove funkcije se vezuje za naziv alata koji se pokreće (vrednost atributa uz –tool=atribut) i pokreće se aplikacija na putanji naziv_alata/naziv_alata-platforma (primer none/none-nanomips-linux). Detekcija nanoMIPS platofme prilikom pokretanja Velgrinda je prikazana na listingu 2.

```
static const char *select_platform(const char *clientname)
...
                    (header.ehdr32.e_flags & E_MIPS_ABI2)) {
                  platform = "mips64-linux";
               }
+              else
+              if (header.ehdr32.e_machine == EM_NANOMIPS &&
+                  (header.ehdr32.e_ident[EI_OSABI] == ELFOSABI_SYSV ||
+                   header.ehdr32.e_ident[EI_OSABI] == ELFOSABI_LINUX)) {
+                 platform = "nanomips-linux";
+              }
           }
```

Listing 2 - Detekcija nanoMIPS platforme prilikom pokretanja Velgrinda

Guest deo Velgrinda predstavlja spregu klijentskog koda (u ovom slučaju mašinski kod nanoMIPS aplikacije) i Velgrindovog IR koda, odnosno vrši disasembliranje mašinskog koda konkretne arhitekture u IR kod. Prilikom učitavanja mašinskog koda, Velgrind poziva arhitekturalno zavisnu funkciju na koju pokazuje *disInstrFn* – *disInstr_nanoMIPS*. Zahvaljujući hijerarhijskoj podeli instrukcijskog skupa nanoMIPS u akumulacija instrukcija, disasembliranje je implementirano shodno podeli instrukcija u instrukcijskom setu – jedna funkcija obrađuje jednu akumulaciju instrukcija. Na sledećem listingu je prikazan prvi nivo disasembliranja akumulacije instrukcija P.ADDIU, koji predstavlja podskup akumulacije P32 (prikazan na slici 2). Deo funkcije koji je prikazan u zavisnosti od dela mašinskog koda instrukcije *rt* vrši disasembliranje instrukcije (ADDIU rt, rs, u), odnosno dalje disasembliranje akumulacije instrukcija P.RI.

```
+static void dis_nanoMIPS32(DisResult *dres, UInt cins)
+{
+
+   switch (cins >> 26) {
+      case P_ADDIURI: {
+         UChar rt = (cins >> 21) & 0x1F;
+
+         if (rt != 0) {
+            UChar rs = (cins >> 16) & 0x1F;
+            UInt u = cins & 0xFFFF;
+            DIP("addiu r%u, r%u, %u", rt, rs, u);
+            putIReg(rt, binop(Iop_Add32, getIReg(rs), mkU32(u)));
+         } else {
+            nano_pri(dres, cins);
+         }
+
+         break;
+      }
....
```

Listing 3- Deo funkcije za disasembliranje mašinskog koda

Nakon disasembliranja, Velgrind izvršava optimizacije nad kreiranim IR kodom, instrumentalizaciju, gradnju stabla i odabir registara. Poslednja faza rada Velgrinda predstavlja *host* deo Velgrinda, odnosno asembliranje Velgrindovog IR koda u kod ciljne arhitekture. Poput izvrašavanja disasembliranja, i asembliranje je arhitekturalno zavisno i izvršava se pozivanjem funkcija na koju pokazuju *iselSB* i *emit* - *iselSB_NANOMIPS* i *emit_NANOMIPSInstr*. Prva od dve funkcije prevodi IR stablo u linearnu strukturu instrukcija koje treba generisati, dok druga "emituje" nanoMIPS instrukcije, odnosno generiše mašinski kod odabranih instrukcija. Funkcija *iselSB* (*iselStatementsBlocks*) prolazi

kroz iskaze u bazičnom bloku pozivajući funkciju *iselStmt* koja transformiše IR instrukciju u ekvivalentnu nanoMIPS instrukciju čiji mašinski kod kasnije generišemo. Deo funkcije je prikazan na slici 6. Funkcija koja generiše mašinski kod nanoMIPS instrukcija (*emit*) koristi informacije koje Velgrind postavlja tokom izvršavanja *isel* funkcije, formira mašinski kod i „emituje“ ga u izlazni bafer.

```
+static void iselStmt(ISelEnv * env, IRStmt * stmt)
+{
+   if (vex_traceflags & VEX_TRACE_VCODE) {
+      vex_printf("\n-- ");
+      ppIRStmt(stmt);
+      vex_printf("\n");
+   }
+
+   switch (stmt->tag) {
+      case Ist_Store: {
+         IRType tyd = typeOfIRExpr(env->type_env, stmt->Ist.Store.data);
+         HReg r_addr = iselWordExpr_R(env, stmt->Ist.Store.addr);
+
+         if (tyd == Ity_I8 || tyd == Ity_I16 || tyd == Ity_I32) {
+            HReg r_src = iselWordExpr_R(env, stmt->Ist.Store.data);
+            addInstr(env, NANOMIPSInstr_Store(sizeofIRType(tyd),
+                                              r_addr, 0, r_src));
+            return;
+         } else if (tyd == Ity_I64) {
+            HReg vHi, vLo;
+            iselInt64Expr(&vHi, &vLo, env, stmt->Ist.Store.data);
+            addInstr(env, NANOMIPSInstr_Store(4, r_addr, 0, vLo));
+            addInstr(env, NANOMIPSInstr_Store(4, r_addr, 4, vHi));
+            return;
+         }
+
+         break;
+      }
...
```

Listing 4 - Deo funkcije za transformaciju IR instrukcije u nanoMIPS instrukciju

VII. TESTIRANJE REŠENJA

Za potrebe testiranja je napisano nekoliko testova za nanoMIPS arhitekturu koja testira validnost dodatih delova disasembliranja i asembliranja prilikom rada Velgrinda. Ovim testovima je pokriven celokupan instrukcijski set nanoMIPS arhitekture. Testiranje je vršeno pomoću QEMU emulatora za nanoMIPS, usled neposedovanja odgovarajućeg hardvera. Trenutnu verziju rešenja podrške treba koristiti sa oprezom, s obzirom da je nepotpuna i nedovoljno testirana sa postojećim skupom Velgrind testova.

VIII. ZAKLJUČAK

U ovom radu opisan je ukratko način rada alata Velgrind,alata kao i nova arhitekura nanoMIPS. Prikazan je način implementacije podrške Velgrind alatu za novu arhitekturu (u ovom slučaju nanoMIPS), što predstavlja značajnu podršku korisniku prilikom testiranja aplikacija. Predstavljeno rešenje je potrebno dodatno testirati koristeći postojeći Velgrindov skup testova za verifikaciju. Cilj testiranja jeste uspešno izvršavanje celokupnog skupa pomenutih testova, te se tada implementacija može nazvati kompletnom.

ZAHVALNICA

Zahvaljujem se Petru Jovanoviću, šefu MIPS grupe, kao i celom Velgrind timu (Aleksandru Rikalu i Aleksandri Karadžić). Takođe, zahvaljujem se i naučno-istraživačkom institutu „RT-RK“ na pruženoj šansi da ovaj rad nastane kao proizvod višemesečnog rada na realnom problemu iz oblasti kojom se rad bavi.

ABSTRACT

Introducing of the new architectures of microprocessor systems in addition to a hardware chip implies certain software tools, such as compilers and emulators. The use of new architecture, the robust creation of complex applications for the new architecture, raises the need for software tools that would facilitate the detection of improper program performance and easier detection of errors, such as debugger and profilers. This paper describes the changes that are needed to add support to one software program analysis tool, Valgrind, for the new architecture of the MIPS Technologies Group - nanoMIPS.

Unapređenje programskog prevodioca za jezik P4 sa podrškom za čitanje međukoda u formatu JSON

Jelena Vidaković, Enisa Hadžić, Miodrag Dinić, Dragan Samardžija

***Apstrakt*— P4 je programski jezik visokog nivoa koji je dizajniran da omogući programiranje prosleđivanja mrežnih paketa nezavisno od vrste protokola. P4 prevodilac je otvorenog koda koji održava neprofitna organizacija pod nazivom 'P4 Jezička Zajednica'. Jezik je prvobitno opisan u dokumentu 'SIGCOMM CCR' iz 2014. godine pod nazivom 'Programming Protocol-Independent Packet Processors' – odakle seže skraćenica P4. On radi zajedno sa kontrolnim protokolima softverski definisanog umrežavanja (SDN), kao što je '*OpenFlow*'. Koristimo apstraktni model prosleđivanja za definisanje jezika kako bi se opisao način na koji će se konfigurisati *switch*-evi i kako se paketi obrađuju.**

***Ključne reči*—P4, P4 prevodilac, simple_switch, BMv2, eBPF**

I. UVOD

S obzirom da je jezik namenjen za aplikacije čiji osnovni cilj jeste prosleđivanje paketa, jezik je dizajniran kako bi ispunio posebne ciljeve koji bi to omogućili. Prvi princip je 'Target independence' što predstavlja dizajniranje programa koji su nezavisni od implementacije, odnosno od uređaja na kome će se izvršavati. Ideja je da prevodilac uzima u obzir mogućnosti *switch*-a, kada pretvara program napisan u p4 jeziku u rezultat koji je zavistan od hardvera i koji se koristi za konfigurisanje *switch*-a. Drugi princip je nezavisnost od vrste protokola. *Switch* ne bi trebalo da bude usko vezan za određeni format paketa, već bi trebalo da postoji mogućnost da se specificira način parsiranja paketa za odvajanje polja zaglavlja i specificiranje tipova i grupa akcija i tabela koji obrađuju ova zaglavlja. Poslednji princip pruža mogućnost da se redefinišu već sačuvana pravila parsiranja paketa i procesiranja pojedinačnih polja.

Cilj ovog rada je upoznavanje sa P4 jezikom i radom P4 prevodioca, strukturama koje formira i načinom na koji čuva stanje programa u njima. Opisana je implementacija prolaza i metoda koje prevodilac poziva, odnosno sama arhitektura i organizacija. Nakon upoznavanja sa osnovnim principima uvodi se u detaljan opis unapređenja prevodioca u vidu podrške za čitanje međukoda u JSON formatu.

II. UVOD U P4 TOK PODATAKA

[1]Pakete koji pristižu prvo obrađuje parser, za telo paketa se pretpostavlja da je skladišteno zasebno pa zbog toga nije dostupno za podudaranje bez prethodnog procesiranja. Parser prepoznaje i izdvaja polja zaglavlja i na taj način definiše protokole koje treba da podržava *switch*. Sam model ne pretpostavlja tip protokola, već mu je važno da postoji već isparsiran prikaz polja zaglavlja nad kojima rade tabele podudaranja i akcija.

Polja zaglavlja, koja su prethodno izdvojena iz istog, prosleđuju se gore pomenutim tabelama. Tabele podudaranja i akcija su podeljene izmedju ulaznog i izlaznog kontrolnog bloka. Dok obe kontrole mogu da modifikuju zaglavlje paketa, ulaz postavlja izlazni port i određuje u koji red će biti smešten paket. Na osnovu ulaznog procesiranja, paket može biti prosleđen, ponovljen, odbačen ili da predstavlja okidač kontrole protoka. Izlaz može izvršavati modifikacije u zaglavlju paketa za svaku instancu, kao što su kopije za višestruko slanje.

Paket može sa sobom da nosi dodatne informacije prilikom prolaska kroz različite faze, ti podaci se čuvaju u strukturi koja se naziva 'metapodatak' i koja se obrađuje na isti način kao i polja zaglavlja paketa. Neki primeri metapodataka uključuju izlazni port, odredište za slanje i red čekanja, kao i vremensku oznaku koja se koristi prilikom raspoređivanja paketa.

III. P4 KONCEPTI

Osnovne jezičke komponente P4 jezika sa svojim definicijama su [2]:

- *Zaglavlja* - predstavljaju sekvencu ili strukturu sačinjenu od niza polja, u kojima se čuva informacija o dužini polja i ograničenjima koja važe za ta polja.
- *Parseri* - specificiraju način na koji se prepoznaju i validaraju zaglavlja i polja unutar njih. Parser može imati više definisanih stanja. Verifikaciju započinje unutar stanja '*start*' i nastavlja dok ne naiđe na stanje '*stop*' ili stanje '*greške*'. Kada uđe u naredno stanje, na osnovu vrednosti određenih polja zadaje se stanje tranzicije[3].
- *Tabele podudaranja i akcija* - predstavljaju mehanizam

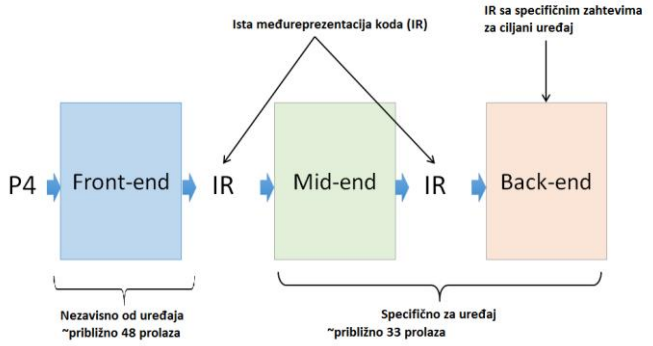
obrade paketa, a sam P4 program definiše polja nad kojima se ta pravila izvršavaju.

- *Akcije* - predstavljaju manipulaciju podacima koji se nalaze u poljima paketa i sadržinom metapodataka. U kontekstu P4 jezika metapodaci su informacije o paketu koje nisu dirketno rezultat parsiranja. P4 definiše metapodatke koji svi uređaji moraju da podrže, a postoji i opcija dodavanja novih korisnički definisanih za specifične uređaje.
- *Kontrole* - određuju redosled poziva akcija i tabela koje se izvršavaju nad podacima i regulišu tok kontrole.

IV. PREVOĐENJE P4 PROGRAMA

Prevodilac se koristi za sintaksnu i leksičku analizu programa, identifikaciju zavisnosti i traženje mogućnosti za obradu zaglavlja. On prevodi P4 program u određenu među reprezentaciju koda koju čuva u grafu zavisnosti koji dalje analizira kako bi utvrdio njihovu validnost i generiše kod za njihovo izvršavanje.

Prevodilac je otvorenog koda i sadrži lako proširivu arhitekturu, kako bi bilo omogućeno jednostavno dodavanje novih prolaza i optimizacija. Projekat prevodioca je implementiran u programskom jeziku $C++_{11}$. Modularna arhitektura projekta omogućava lako dodavanje novih funkcionalnosti i održavanje obe trenutno podržane verzije standarda jezika $P4_{14}$ i $P4_{16}$. Podrška za ove standarde je podeljena u 2 odvojena modula za prvu fazu procesiranja (eng. 'front-end'), pretvarač $P4_{14}$ u $P4_{16}$, narednu fazu optimizacije (eng. 'mid-end') i tri 'back-end' prototipa (sa skraćenicama eBPF, bmv2 i p4test). EBPF 'back-end' generiše .c kod , BMV2 generiše .json izlazni fajl koji se koristi za pokretanje 'simple-switch' mrežnog simulatora i poslednji 'p4-test' koji predstavlja 'lažni back-end', odnosno koristi se za testiranje, debagovanje i bolje razumevanje rada prevodioca.



Sl. 1 : Struktura prevodioca

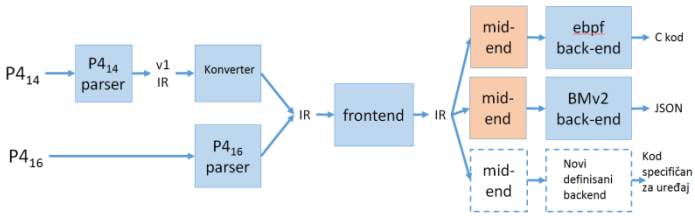
[4]Struktura prevodioca je grafički prikaza na slici 1, i sastoji se od tri osnovne faze pod nazivima Front-end, Mid-end i Back-end.

Front-end je u potpunosti nezavistan od arhitekture, unutar sebe poziva dodatne prolaze (ima ih približno 48) koji vrše validaciju programa, proveru tipova i dodatna promatranja:

- Parsiranje programa
- Validacija
- Razrešavanje imena
- Provera tipova
- Rešavanje bočnih efekata
- Optimizacija
- Razrešavanje 'Inline' funkcija
- Konvertovanje u P4 izvorni oblik

Mid-end je drugačiji za svaki uređaj, pokreće dodatne prolaze koji vrše optimizaciju, predikciju koda i eliminaciju suvišnih tipova. Poslednja faza prevođenja je deo modula pod nazivom Back-end, on je u potpunosti zavisan od uređaja, vrši alokaciju resursa i generisanje koda. Unutar prevodioca postoji jasna podela među prolazima odakle seže i svojstvo proširivosti, tj lakog dodavanja novih prolaza ili čak čitavog 'back-end'-a zavisnog od uređaja.

Tok prevođenja izvornog koda P4 programa može se grafički predstaviti slikom br.2.



Sl. 2 : Protok podataka

$P4_{14}$ izvorni kod prolazi kroz $P4_{14}$ parser, zatim kroz pretvarač kako bi se dobio isti međukod, koji daje $P4_{16}$ parser. Međureprezentacija koda prolazi kroz 'front-end' i zajednička je za svaki uređaj kome će biti prosleđena. 'Mid-end' i 'Back-end' su karakteristični za različite hardvere i za svaki je definisan drugačiji izlazni format koji generiše. Ovakvom organizacijom prevodioca omogućeno je dodavanje podrške za novi ciljani uređaj.

Na početku izvršavanja prevođenja poziva se parser, koji je implementiran koristeći generator leksičkih analizatora *Flex* i parser generator *Bison*. Nakon parsiranja fajla, pravi se instanca Front-End-a koji izvršava provere i čuva stanje programa, a nakon te faze i faza Mid-End u kojoj se nad datim programom izvršavaju i dodatne optimizacije. Najvažniji prolazi koji se moraju pozivati svaki put kada se promeni nešto u program su 'ResolveReferences' i 'TypeInference'. 'Evaluator' se poziva posle celokupne Front-End i Mid-End faze i koji formira hijerarhiju statički alociranih resursa. Navedeni 'ResolveReferences' prolaz popunjava strukturu 'ReferenceMap', pritom mapira i povezuje svako pojavljivanje promenljive sa njenom deklaracijom. Naredni 'TypeChecking' prolaz vrši proveru tipova, za njegovo izvršavanje je neophodna popunjena 'ReferenceMap'-a, a kao rezultat dobija se popunjena struktura 'TypeMap' koja je takođe neophodna za dalje prevođenje programa. 'TypeMap' predstavlja mapu, koja se popunjava za svaki čvor koji poseduje informaciju o izvornom tipu.

P4 prevodilac u sebi sadrži podršku za četiri različita 'back-end' prototipa. Jedan od njih je 'p4test', njegovo izvršavanje je znatno redukovano i služi samo za testiranje prva dva

prolaza prevođenja, tj Front-end i Mid-end prolaza. ‘P4test’ prevodi fajl i čuva P4 reprezentaciju programa nakon izvršavanja pomenutih faza i na taj način testira njihovu validnost. Implementacija ovog prototipa sadrži podršku za p4 programe napisane u verziji 14 i 16. Podržan je i ‘p4c-ebpf’, rezultat njegovog izvršavanja je .c kod, koji dalje može biti preveden u eBPF. BPF (eng. ‘The Berkeley Packet Filter’) podržava filtriranje paketa, dozvoljavajući korisničkom procesu da obezbedi filter koji specificira koje pakete želi da primi. ‘P4c-bm2’ u sebi sadrži dva ‘back-end’-a, ‘p4c-bm2-ss’ i ‘p4c-bm2-psa’. ‘Psa’ prototip nije u potpunosti realizovan, tj za njega se smatra da je u fazi implementacije. Celokupan ‘p4c-bm2 back-end’ kao izlaz prevođenja čuva stanje u .json formatu koji predstavlja ulazni fajl za ciljani uređaj ‘Behavioral Model version 2’, odnosno softverski switch nazvan ‘simple_switch’. ‘P4c-bm2-psa’ ima podršku za sve p4 programe koji su napisani za ‘psa.p4’ model u verziji 14 ili 16. PSA model generiše kod za arhitekturu prenosnog prekidača (eng. ‘The Portable Switch Architecture’) koja opisuje mogućnosti uređaja mrežnog prekidača koji obrađuje i prosleđuje pakete na više portova interfejsa. Drugi ‘p4c-bm2-ss’ takođe generiše kod za pomenuti mrežni simulator i prevodi $p4_{14}$ i $p4_{16}$ programe napisane koristeći ‘v1model.p4’. Navedeni JSON format je format otvorenog standarda, nezavistan od programskog jezika, koji koristi zapis čitljiv čoveku i kome se prenose različiti objekti podataka.

V. Unapređenje prevodioca

Realizacija rešenja opisanog u ovom radu proizvod je težnje da se arhitektura p4 prevodioca dodatno unapredi tako da se platformski nezavisan međukod može iznova koristiti za različite platforme, bez potrebe da se izvorni P4 program podvrgne svim fazama prevođenja. Do sada je u prevodiocu postojala mogućnost da se nakon Mid-End prolaza sačuva međureprezentacija koda. Prosleđivanjem argumenata komandne linije ‘--toJSON’ i ‘fajl.json’ , prevodilac će sačuvati međukod programa u navedenu .json datoteku.

Radi boljeg razumevanja rešenja i unapređenja opisanih u daljem radu, u nastavku su navedene komande prevodioca koje pokreću njegovo izvršavanje. Kao primer, navedene su komande za *bmv2/simple_switch* ‘back-end’.

(1) p4c-bm2-ss -o izlazniFajl.json izvorniFajl.p4 --toJSON fajl.json

(2) p4c-bm2-ss -o izlaz.json --fromJSON fajl.json

Grafički prikaz toka prevođenja uz unapređenje dat je na slici 3.

Sl. 3 : Struktura prevođenja

Prilikom generisanja sadržaja programa, podrazumevano ponašanje je da se informacije o izvornom kodu svakog čvora ne čuvaju u međureprezentaciji. Implementacija je proširena podrškom da se kao deo svakog čvora sada čuvaju i te informacije o izvornom kodu kako bi se dobili svi neophodni podaci za dalje rekonstruisanje.

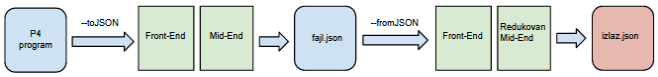
Prvi korak je dodavanje podrške za prepoznavanje novog argumenta komandne linije, ‘--fromJSON’ ‘fajl.json’. Nova opcija komandne linije prevodioca zaštićena je od nenamernih grešaka korisnika i testirana u kombinaciji sa svim ostalim do sada podržanim opcijama. Ukoliko je umesto očekivanog formata nakon *flag*-a(--fromJSON) naveden neki drugi, npr .p4 format, obezbeđeno je da prevodilac prijavi grešku. Ova podrška dodata je za sva četri delimično ili u potpunosti implementirana ‘back-end’-a. Prilikom kreiranja bilo kojeg od objekata koji predstavljaju strukturu u kojoj se čuva stanje svih navedenih opcija koje prevodilac treba da podrži i koji su zasebni za svaki ‘back-end’, definiše se novi ‘registerOption(--fromJSON, file)’, grafički prikaz na slici 4.

```
registerOption("--fromJSON", "file",
       [this](const char* arg) { loadIRFromJson = true; file = arg; return true; },
       "Use IR representation from JsonFile dumped previously,"\
       "the compilation starts with reduced midEnd.");
```

Sl. 4 : Dodavanje opcije komandne linije

Za rekonstruisanje stanja programa (unutar klase P4Program) zadužen je poseban modul (klasa JSONLoader) koji to čini pomoću informacija iz datoteke koja čuva međureprezentaciju u formatu JSON. Bilo je neophodno dodati podršku za kreiranje JsonObject-a (strukture u kojoj se čuva i formira jedan pročitan objekat) popunjavanjem njegovog polja SourceInfo (odnosno strukture koja nosi informaciju o izvornom kodu). Implementacija je postignuta proširenjem klasa novim konstruktorima, metodama i poljima koji čuvaju novonastalo stanje.

Prikaz faza prevođenja i toka dat je na slici 5.



Sl. 5 : Struktura prevođenja (sa i bez ‘--fromJSON’)

Ukoliko se komandom prevođenja navede ‘--fromJSON’ a prethodno je u nekom fajlu sačuvana međureprezentacija, umesto ponovnog parsiranja, čitaju se već optimizovani podaci i postupak prevođenja se nastavlja u znatno redukovanom obimu. Pošto su podaci izgenerisani nakon Mid-End prolaza, sve optimizacije nad čvorovima programa su već izvršene, pa ih nije potrebno ponovo pozivati. Prevođenje započinje čitanjem iz fajla i rekonstruisanjem stanja, a nakon toga poziva se redukovan Mid-End i Back-End prolaz. Mid-End je neophodno ponovo pokrenuti jer se strukture koje se popunjavaju u jednom delu njegovog izvršavanja prosleđuju kao argumenti Back-End-a. Redukovan prolaz čine ‘ResolveReferences’ koji će popuniti strukturu ‘refMap’ , ‘TypeChecking’ koji popunjava strukturu ‘TypeMap’ , ‘VisitFunctor’ koji poziva ‘evaluator’ prolaz i

popunjava strukturu ‘IR::ToplevelBlock’. Jedan od poziva unutar ‘Back-end’-a generiše se na osnovu strukture, koja se popunjava iz ulaznog fajla prilikom parsiranja. Pošto se ovim putem samo parsiranje izbegava, onda i ta struktura ostaje nepopunjena i time svako čitanje podataka iz nje postaje nevalidno. Stoga se ovaj prolaz (sa nazivom ‘ParseAnnotation’) dodaje prevođenju, samo ukoliko flag ‘--fromJSON’ nije prosleđen kao argument komandne linije.

Ispisivanju sadržaja u izlazni .json format, prethodile su izmene prilikom kreiranja polja JsonObject-a. Zbog izmenjenog ulaznog fajla i načina čitanja, time i drugačijeg načina formiranja pojedinih objekta, metoda ‘prepareSourceInfoForJSON’ , čiji zadatak je da modifikuje polja objekta u čitljiviji zapis, neće ispisivati validno vrednosti sačuvane unutar navedenog SourceInfo polja. Za rešenje ovog problema primenjena je simulacija kreiranja novog JsonObject-a, kome su kao parametri prosleđeni novosačuvani podaci. Nakon toga omogućeno je regularno ispisivanje ovog objekta u izlazni .json fajl.

Prvobitno rešenje sa redukovanim Mid-End prolazom u izlaznom fajlu nije sadržalo informacije o korisnički definisanim enum tipovima. Unutar koda prevodioca čuva se struktura ‘enumMap’ koja se popunjava prilikom izvršavanja prolaza ‘convertEnumPass’. Ovaj prolaz je sastavni deo Mid-End dela i njegov zadatak je da koristeći korisnički definisane smernice konvertuje enum tipove u tip bit<n>. Konverzija se vrši samo nad korisnički definisanim, odnosno ne odvija se nad enum tipovima koji su deo specifikacije arhitekture. Nakon obrađivanja čvora koji je tipa ‘Type_Enum’ vrši se popunjavanje navedene strukture ‘enumMap’ i njegovo uklanjanje iz vektora čvorova. Kada se nakon Mid-End-a izgeneriše međureprezentacija koda unutar nekog fajla, ‘convertEnumPass’ prolaz je već izvršio optimizacije i time uklonio sadržaj enum tipova iz programa. Nakon ponovnog prevođenja opcijom ‘--fromJSON jsonFile.json’, nedostajaće podaci o ovim tipovima koje je korisnik definisao prilikom pisanja .p4 programa. Rešenje koje je ponuđeno za prevazilaženje ovog problema je proširenje redukovanog Mid-End-a. Izmena koja je predstojila ovom proširenju, odnosno uvođenju novog prolaza, je čuvanje svih čvorova u programu nakon njihove obrade. Kada je to postignuto, zagarantovano je i validno čuvanje čitavog sadržaja programa u međureprezentaciji, a time i validno čitanje iz novog ulaznog fajla. ‘FillEnumMap’ je novi prolaz koji će prilikom obrade popuniti strukutru ‘enumMap’ i time obezbediti da se ispisivanje sadržaja u izlazni .json fajl obavi nepromenjeno.

Grafički prikaz redukovanog i finalnog Mid-End prolaza je dat na slici 6[5].

```
auto fillEnumMap = new P4::FillEnumMap(new PsaEnumOn32Bits("psa.p4"), &typeMap);
addPasses({
    new P4::ResolveReferences(&refMap),
    new P4::TypeChecking(&refMap, &typeMap),
    fillEnumMap,
    new VisitFunctor([this, fillEnumMap]() { enumMap = fillEnumMap->repr; }),
    evaluator,
    new VisitFunctor([this, evaluator]() { toplevel = evaluator->getToplevelBlock(); }),
});
```

Sl. 6: Redukovan Mid-End

VI. Testiranje rešenja

Unutar koda prevodica nalaze se testovi koji pokreću prevođenje i njihovu simulaciju. Komandom ‘*make check*’ moguće je pokrenuti njihovo izvršavanje i na standardnom izlazu ispratiti status i procenat uspešnosti. Nad unapređenjem navedenim u ovom radu, pokrenutu su svi testovi koji su podržani aktuelnom verzijom kompjalera u trenutku podizanja izmena, sa procentom uspešnosti od 100%.

Konkretno, sama realizacija rešenja je testirana poređenjem izlaznih fajlova koje svaki ‘back-end’ ponaosob izgeneriše (.json, .c, .graphs). Izlazni fajl koji je izgenerisao neizmenjen kod kompajlera komandom (1) u sebi sadrži iste informacije kao i izlazni fajl koji je izgenerisan komandom (2), odnosno unapređenim prevodiocem. Smatrajući to korektnim uslovom ispravnosti rada kompajlera, realizacija ovog unapređenja se može smatrati validnom[6].

VII. Zaključak

U ovom radu dat je uvod u p4 jezik i p4 prevodilac. Ukratko je opisana struktura i organizacija koda, kao i tok izvršavanja prevođenja za različite ciljane uređaje. Prikazano je unapređenje u vidu dodavanja podrške za čitanje međukoda u JSON formatu, što predstavlja značajnu podršku korisnicima. Uz efikasnost i brže reprodukovanje prevođenja, kao rezultat je dobijena i mogućnost da se isti međukod prosleđuje različitim uređajima na izvršavanje i poređenje.

Zahvalnica

Zahvaljujem se Miodragu Diniću, Draganu Samardžiji, kao i P4dev timu, Enisi Hadžić, na saradnji i pruženom znanju. Takođe, zahvaljujem se i naučno-istraživačkom institutu „RT-RK“ na pruženoj šansi da ovaj rad nastane kao proizvod višemesečnog rada na realnom problemu iz oblasti kojom se rad bavi. Ovaj rad je delimično finansiran od strane Ministarstva za prosvetu, nauku i tehnološki razvoj Republike Srbije, na projektu broj: TR36029.

Unapređenje jezika P4 izrazima assume i assert kao pomoć u formalnoj verifikaciji

Enisa Hadžić, Jelena Vidaković, Miodrag Dinić, Miroslav Popović

***Apstrakt*— P4 je jezik otvorenog koda koji je dizajniran tako da se koristi za programiranje mrežnih uređaja. Razvoj P4 jezika uneo je veću fleksibilnost u mrežno programiranje i omogućio da uređaj postane rekonfigurabilan i nezavisan od protokola. Osnovni tok podataka u P4 jeziku može da se podeli u 4 osnovne faze. Prva faza je parsiranje mrežnih paketa. Prilikom prijema paketa, polja paketa moraju biti procesirana i sačuvana u reprezentaciji koja je čitljiva narednim fazama. Druga i treća faza je primena podudaranja i akcija tabela na ulaznom i izlaznom toku kontrole. Njihovo izvršavanje predstavlja mehanizam obrade parsiranih podataka i manipulaciju informacija sadržanih unutar polja paketa. Kako bi paket mogao da se dalje prosledi ciljanom uređaju, neophodno je da prođe kroz poslednju fazu deparsiranja, koja će emitovati obrađeno stanje paketa. U ovom radu biće predstavljen P4 jezik i način rada prevodioca, kao i način unapređenja novim izrazima assert i assume.**

***Ključne reči*—P4, Bmv2, prevodilac, data-plane**

I. Uvod

P4 [1] predstavlja jezik koji je namenjen za izražavanje načina na koji će se paketi obrađivati od strane *data-plane* programibilnog elementa kao što su mrežne kartice i ruteri. Programibilnost načina prosleđivanja olakšava operaterima da brzo implementiraju nove protokole i razvijaju mrežne usluge. Koristeći P4 jezik, moguće je specificirati kako treba manipulisati sa zaglavljima pristiglih paketa od strane različitih prosleđivačkih uređaja u infrastrukturi. Uprkos pomenutoj fleksibilnosti, ova paradigma takođe povećava šanse za pojavljivanje kvara u mreži. Traženje razloga nepravilnog rada mrežnih sistema može biti dug i skup proces, jer moderni uređaji podržavaju desetine različitih formata paketa i protokola. Dosadašnji pristup testiranju je da se izvrši iscrpno poređenje ulaznih paketa i očekivanih izlaznih paketa.

Enisa Hadžić, Naučno istraživački institut RT-RK, Bulevar Milutina Milankovića 19a, 11000 Beograd, Srbija (telefon 381-21-483-1491, e-mail: enisa.hadzic@rt-rk.com).

Miodrag Dinić, Naučno istraživački institut RT-RK, Bulevar Milutina Milankovića 19a, 11000 Beograd, Srbija (telefon: 381-21-483-1489, e-mail: miodrag.dinic@rt-rk.com).

Miroslav Popović, Univerzitet u Novom Sadu, Fakultet tehničkih nauka, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (telefon 381-21-480-104, e-mail: miroslav.popovic@rt-rk.uns.ac.rs).

Kako sada programer opisuje funkcionalnost uređaja koristeći P4 jezik, dolazi se do ideje za uvođenje *assert* i *assume* izraza koji se koriste prilikom testiranja P4 programa.

II. Uvod u P4 jezik

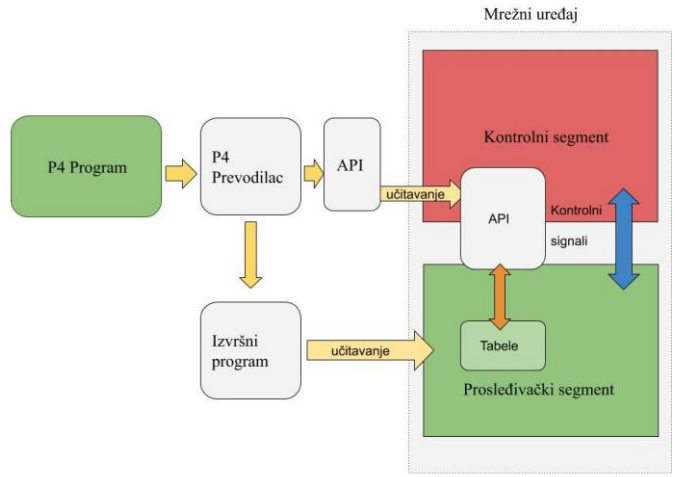
P4 je relativno jednostavan i statički tipiziran programski jezik, dizajniran da izrazi transformacije nad mrežnim paketima. Trenutna verzija $P4_{16}$ je 1.1.0, objavljena u novembru 2018. godine. Primarni ciljevi P4 jezika su da bude:

- Hardverski nezavisan
- Nezavisan od protokola
- Rekonfigurabilan

Osnovne apstrakcije koje pruža P4 jezik su:

- Zaglavlja (engl. *header*) – opisuju format svakog zaglavlja u mrežnom paketu
- Definisani meta podaci – skup podataka koji su povezani sa svakim paketom
- Parseri – opisuju dozvoljene sekvence zaglavlja unutar primljenog paketa i način na koji se identifikuju
- Akcije – fragmenti koda koji opisuju način na koji se manipuliše sa zaglavljima paketa
- Tabele – povezuju ključeve koje definiše korisnik sa odgovarajućom akcijom. Prilikom primenjivanja tabele izvšava se pretraživanje tabele sa ključem koji se dobije iz paketa i ako se desi podudaranje sa nekim od ulaza iz tabele koja se pretražuje, odgovarajuća akcija iz tog ulaza se izvršava
- Kontrolni blokovi – uključuju sekvencu pozivanja tabela
- Deparser – konstruiše izlazni paket od procesiranih zaglavlja ulaznog paketa

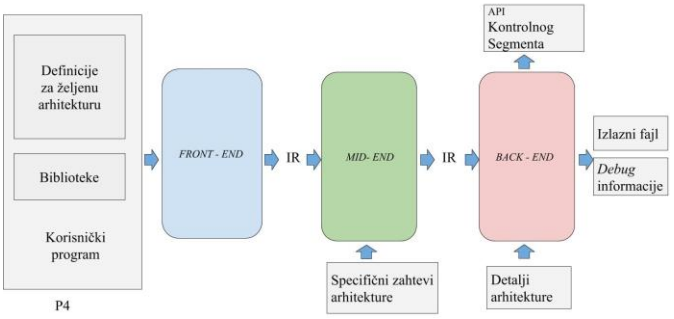
Na slici 1 nalazi se ilustrovani prikaz toka rada za programiranje mrežnog uređaja koristeći P4 jezik. Napisani P4 program prosleđuje se prevodiocu koji generiše izlaz u odgovarajućem formatu. Prevodilac ne samo da sintetiše funkcionalnosti prosleđvanja, već i API (skr. *application program interface)* između *control plane* i *data plane* jedinica.



Sl. 1. Programiranje mrežnog uređaja koristeći P4 jezik

III. ARHITEKTURA P4 PREVODIOCA

Da bi se implementirao P4 program, potreban je prevodilac za generisanje odgovarajuće konfiguracije za ciljni uređaj. P4 prevodilac [2] napisan je u C++ [3] programskom jeziku i dizajniran je tako da iz prosleđenog P4 programa generiše odgovarajuću reprezentaciju, izvršava više prolaza koji transformišu i optimizuju željeni program. Na samom početku rada prevodioca izvršava se sintaksna i leksička analiza P4 programa koji se prevodi. Parser koji se koristi generisan je od strane Bison [4] parser generatora i Flex [5] generatora leksičkih analizatora. Tok rada prevodioca posle sintaksne i leksičke analize može da se podeli na tri celine: *frontend*, *midend* i *backend*. Na slici 2 prikazan je tok rada prevodioca prilikom prevođenja ulaznog P4 programa.



Sl. 2. Faze prevođenja ulaznog P4 programa

Frontend prolaz vrši parsiranje izvornog programa i formira internu reprezentaciju (IR) koja odgovara tom izvornom kodu. Zatim se izvršava više prolaza koji vrše odgovarajuće provere koje P4 program mora da zadovolji kako bi bio semantički ispravan. Ukoliko u nekom od prolaza prevodilac utvrdi neregularnost programa koji se prevodi, biće prikazana odgovarajuća greška i proces prevođenja se završava neuspešno.

Za razliku od *frontend* prolaza, *midend* i *backend* se razlikuju za svaki ciljni uređaj za koji se vrši prevođenje. U *midend* prolazu, vrše se optimizacije interne reprezentacije koje obavljaju predikciju, uklanjaju nepotreban kod i pojednostavljuju izraze. Nakon *midend* prolaza, optimizovana interna reprezentacija programa se dodatno optimizuje u backendu i generiše se kod u zavisnosti od ciljnog *backend* prolaza. Trenutno u P4 prevodiocu postoje četiri različita *backend* prolaza:

- Bmv2 (*Behavioral model version 2* [6])
- Ebpf (*Extended Berkeley Packet Filter*)
- P4test
- Graphs

P4test služi za testiranje parsiranja, *frontend* i *midend* prolaza, dok *graphs* služi za generisanje grafičkog prikaza programa koji se prevodi. *Bmv2 backend* generiše izlazni fajl u json formatu, koji se koristi kao ulaz *Behavioral Model* simulatora. Simulator analizira json opis prevedenog P4 programa i konfiguriše tabele, parsere i akcije i formira primitive za svaku podržanu operaciju iz json fajla, koje se zatim izvršavaju i time simuliraju rad sistema. U json fajlu generiše se opis P4 programa u određenom formatu koji je čitljiv čoveku i omogućava prenošenje podataka u Bmv2 simulator. *Ebpf backend* kao izlaz generiše C program koji dalje može da se prevede u *ebpf* format, koristeći BCC ili CLANG, a koji se zatim izvršava pod Linux kernelom.

Svaki od pomenutih prolaza u P4 prevodiocu, realizovan je kao klasa koja je izvedena iz osnovnih klasa za definisanje novih prolaza – *Visitor* i *Transform* klase. Visitor je konstantni prolaz, koji samo obilazi čvor u IR stablu i sakuplja informacije o njemu, dok prolazi tipa *Transform* posećuju čvor i mogu da izvrše promene ili da ga zamene sa drugim čvorom. Ovi prolazi sadrže *preorder* i *postorder* metode za svaki tip IR čvora, koje mogu da se redefinišu. Ovako realizovana arhitektura P4 prevodioca omogućila je lako dodavanje novih prolaza i ciljnih backend-a.

IV. UNAPREĐENJE P4 JEZIKA

Realizacija unapređenja P4 jezika izrazima assert i assume nastala je kao potreba da se olakša način testiranja rada P4 programa. Tokom analiziranja ispravnosti programa, korisno je imati izraze:

assert(<boolean expression>)
assume(<boolean expression>)

Podrazumevano izvršavanje navedenih izraza je proveravanje prosleđenog uslova i ukoliko se ispostavi da je taj uslov netačan, odgovarajuća poruka o grešci se ispisuje i programer dobija informacije o fajlu, uslovu i broju linije zbog koje je došlo do greške. Razlika između ova dva izraza je u formalnoj verifikaciji. Dok se za uslov prosleđen assert izrazu nada da je tačan i proverava se da li je ikada netačan, za assume uslov programer čvrsto veruje da će prosleđeni uslov uvek biti tačan.

Prvi korak u realizaciji rešenja je dodavanje navedenih izraza tako da budu prepoznati od strane P4 prevodioca. Nove funkcije u P4 prevodiocu predstavljene su kao *extern* objekti, koji opisuju samo interfejs tog objekta, ali ne i njegovu implementaciju. Implementacija tih funkcija zavisi od ciljne arhitekture i generiše se u odgovarajućem *backend*-u.

Nalik na *assert* izraz u C++ programskom jeziku, željeno ponašanje je da se omogući i uklanjanje svih assert i assume

izraza iz ulaznog P4 programa ukoliko to programer želi. Da bi se to ponašanje obezbedilo, uveden je novi argument koji se prosleđuje prilikom pokretanja rada P4 prevodioca. Ukoliko se prilikom pokretanja procesa prevođenja P4 programa navede u komandnoj liniji argument *„--ndebug''*, vrednost istoimenog flag-a u P4 prevodiocu će biti postavljena na *true*. Kada je taj flag postavljen u *midend* prolazu se dodaje *RemoveAssertAssume* prolaz koji treba da ukloni sva pojavljivanja *assert* i *assume* izraza iz IR. Navedeni prolaz je implementiran tako da je izveden iz *PassManager* klase koja enkapsulira više prolaza koji će se izvršiti sekvencijalno. U okviru *RemoveAssertAssume* potrebno je da se izvrše dva prolaza: *TypeChecking* i *DoRemoveAssertAssume*. Prvi prolaz je potreban kako bi se izvršilo popunjavanje struktura, koje mapiraju svako pojavljivanje sa deklaracijom i svaki čvor sa tipom, koje su potrebne drugom prolazu. *DoRemoveAssertAssume* prolaz je izveden iz *Transform* klase koja predstavlja osnovnu klasu koja izvršava transformacije nad određenim IR čvorom. *DoRemoveAssertAssume* klasa redefiniše *preorder* metodu koja obilazi objekat IR čvora koji reprezentuje poziv metode ili funkcije u P4 programu. U okviru redefinisane metode izvršava se provera da li je IR čvor koji se obilazi tipa *assert* ili *assume* izraza i ukoliko jeste uklanja iz programa.

U okviru *backend* prolaza kada se utvrdi da čvor koji se obilazi predstavlja *assert* ili *assume* izraz vrši se generisanje koda. Kako *bmv2 backend* generiše fajl u json formatu koji se koristi kao ulaz *Behavioral model* simulatora, uvedene su nove primitive u simulatoru kako bi se ulazni json fajl uspešno pročitao. Deo json fajla koji se odnosi na primitivu *assert* prikazan je na slici 3. Kao što je prikazano, pored naziva primitive i uslova, generiše se i deo koda *source_info* koji sadrži informacije koje su potrebne za ispisivanje greške.

```
"primitives" : [
    {
      "op" : "assert",
      "parameters" : [
        {
          "type" : "expression",
          "value" : {
            "type" : "expression",
            "value" : {
              "op" : "b2d",
              "left" : null,
              "right" : {
                "type" : "bool",
                "value" : false
              }
            }
          }
        }
      ],
      "source_info" : {
        "filename" : "/home/vagrant/Desktop/basic.p4",
        "line" : 122,
        "column" : 1,
        "source_fragment" : "assert(false)"
      }
```

Sl. 3. Prikaz dela json fajla za *assert(false)* izraz

Za svaki IR čvor ulaznog programa generiše se odgovarajući blok koda u json formatu.

Primitive u simulatoru su realizovane kao objekti klase *ActionPrimitive*, koja predstavlja osnovnu klasu za sve primitive koje postoje u projektu. Prilikom parsiranja ulaznog json fajla, za svaku pročitanu operaciju se formira objekat odgovarajuće primitive i doda u red svih primitiva koje su pročitane iz fajla koji je generisao P4 prevodilac. U fazi izvršavanja svih pročitanih primitiva poziva se preklopljena metoda *operator()* svake primitive i izvršava se njeno telo. Kada je reč o *assert* ili *assume* operaciji u telu preklopljene metode izvršava se proveravanje uslova. Ako je uslov netačan to znači da je pretpostavka bila pogrešna i poziva se metoda koja ispisuje poruku o grešci i informacije o fajlu, liniji i uslovu koji je doveo do greške. Te informacije se dobijaju iz objekta klase *SourceInfo* koji je vezan za svaku operaciju i koji se dobija čitanjem json fajla. Nakon ispisivanja informacija o grešci, simulacija se prekida.

V. Testiranje rešenja

U fazi testiranja rada P4 prevodioca korišćeni su testovi koji dolaze uz prevodilac prošireni sa implementiranim izrazima. Testovi su podeljeni u više grupa u zavisnosti od *backend*-a i verzije P4 jezika. Prilikom pokretanja testova za bmv2 backend pokreće se i simulator koji simulira izvršavanje prosleđenog programa. Ukoliko bilo koji od testova generiše izlaz koji se razlikuje od očekivanog, test će da padne i potrebno je proveriti šta je uzrokovalo neregularnost programa.

VI. Zaključak

U ovom radu opisan je P4 jezik i arhitektura prevodioca, kao i simulator za pokretanje izlaza P4 prevodioca. Prikazano je unapređenje jezika izrazima *assert* i *assume* koji za cilj imaju da olakšaju testiranje programa napisanih u P4 jeziku.

VII. Zahvalnica

Zahvaljujem se Miodragu Diniću na pruženom znanju, kao i profesoru Miroslavu Popoviću. Takođe bih se zahvalila koleginici iz P4Dev tima, Jeleni Vidaković, na saradnji, kao i naučno-istraživačkom institutu „RT-RK“ na pruženoj šansi da ovaj rad nastane kao proizvod višemesečnog rada na realnom problemu iz oblasti kojom se rad bavi. Ovaj rad je delimično finansiran od strane Ministarstva za prosvetu, nauku i tehnološki razvoj Republike Srbije, na projektu broj: III44009-6.

Analiza vremenskih serija: Metode predviđanja buduće potražnje u veleprodaji

Aleksandar Stojčić, Nevena Radosavljević, Bratislav Predić, Marko Kovačević, Miloš Roganović

***Apstrakt*— Osnovna namena analize vremenskih serija jeste pojašnjenje korelacije i osnovnih karakteristika hronološki sortitanih podataka korišćenjem odgovarajućih matematičkih modela. Svoju primenu nalazi u najrazličitijim aspektima života i rada, te tako i u predviđanju buduće potražnje proizvoda, usluga, itd. Najzastupljeniji tip vremenske serije jeste onaj kod koga se opservacije uzimaju u jednakim vremenskim intervalima (dnevno, nedeljno, mesečno, itd.). Međutim, u ovom radu analizira se neuobičajena vremenska serija koja beleži trenutke kupovina nekog proizvoda od strane potrošača, i koja se, samim tim što ne postoje regularni periodi uzorkovanja, mora transformisati na odgovarajući način pre nego što se može krenuti sa tradicionalnim metodama analize. Nakon postupka transformacije, u modeliranju vremenske serije u okviru rada korišćen je opšte poznat ARIMA model za analizu nestacionarnih vremenskih serija, koji je odabran zbog izražene komponente sezonalnosti i pomoću koga se uspešno vrši predviđanje buduće potrošnje posmatranog proizvoda. Cilj ovakve analize jeste pravovremeno reklamiranje proizvoda potrošaču radi povećanja prodaje.**

***Ključne reči*— potražnja; analiza vremenskih serija; sezonalnost; ARIMA; prognoza.**

I. Uvod

Vremenske serije su sastavni deo života i rada svih nas. Shodno tome, njihova analiza je statistička disciplina koja beleži najdinamičniji razvoj poslednjih decenija. Kako je proces donošenja odluka često povezan sa predviđanjem budućih vrednosti promenljivih koje zavise od vremena, vremenske serije i njihova analiza predstavljaju pogodno i jako korisno sredstvo. U ovom kontekstu, predviđanje podrazumeva analizu istorijskih podataka i ekstrapolaciju istih u budućnosti uz upotrebu odgovarajućeg matematičkog modela.

Predmet analize ovog rada jeste neregularna vremenska serija koja beleži trenutak kupovine i količinu kupljenog proizvoda od strane potrošača. Neregularna je iz razloga što se uzorkovanje ne vrši u jednakim vremenskim intervalima (dnevno, nedeljno, itd.), već prilikom svake kupovine. Iz tog razloga, ona se ne može analizirati i modelovati klasičnim tehnikama, već je najpre potrebno izvršiti određene matematičke transformacije. Generalna ideja je da se na osnovu kupljene količine i perioda između dve kupovine izračuna prosečna dnevna potrošnja konkretnog proizvoda od strane jednog potrošača. Na taj način se dobija klasična vremenska serija prosečne potrošnje beležene na dnevnom nivou.

Nakon svođenja početne vremenske serije na regularnu, možemo se na dalje baviti problemom njene stacionarnosti. ARMA (*engl. Autoregressive Moving Average*) model pripada grupi stohastičkih modela koji mogu biti korišćeni u simulaciji i analizi stacionarnih vremenskih serija. Ukoliko je, kao u ovom slučaju, vremenska serija nestacionarna, ali se može svesti na stacionarnu, ARIMA model je odgovarajući model za analizu. Sezonski ARIMA (*engl. Autoregressive Integrated Moving Average*) model potiče od klasičnog ARIMA modela, ali kao bitan faktor uključuje i sezonsku komponentu vremenske serije. Zapravo, sezonski ARIMA model je moćno sredstvo u analizi vremenskih serija jer je prilagodljiv čitavom skupu vremenskih serija, bez obzira na regularnost njihove sezonske komponente. Box i Jenkins su sedamdesetih bili pioniri ove metodologije.

S obzirom na složenost matematičkih izračunavanja u izgradnji modela, ovaj rad će se oslanjati na postojeća statistička softverska rešenja – programski jezik R, u računanju i iscrtavanju povezanih grafika.

II. Analiza problema

Kada je reč o analizi kupovina kao i obradi ovih informacija, većina radova, kao i komercijalnih sistema se fokusira na takozvane sisteme preporuke (*engl. recommender system*). Ono što je karakteristično kod ovih sistema jeste to da na osnovu prethodnih kupovina generišu personalizovane preporuke postojećim kupcima. Domen ovih rešenja vezuje se za transakcije koje se vrše direktno između kompanija i potrošača (*engl. Bussines to consumer - B2C*). Problem koji se dosta ređe sreće u literaturi, i čiji je jedan deo obrađen u ovom radu, odnosi se na transakcije veleprodaje koje se vrše između kompanija (*engl. Bussines to bussines - B2B*). Neke od glavnih razlika između ove dve vrste poslovanja koje imaju uticaja na način modelovanja su prikazane su u tabeli 1.

Veleprodaja	Maloprodaja
kupovina 'na veliko'	kupovina par proizvoda
odluke o kupovini donosi komisija	odluke donosi pojedinac
duži period kupovine	kratak period
odluke su racionalne	odluke su emotivne
kupovina 'po potrebi'	kupovina vođena željom

Tabela 1. Poređenje karakterisika veleprodaje i maloprodaje [1]

Sve ovo upućuje na činjenicu da je B2B proces kupovine stabilniji. Racionalnost odluka, duži proces kupovina, kao i veće kupljene količine upućuju na proces koji prati određena pravila i samim tim, kao takav manje je sklon slučajnostima.

Većina istraživanja na ovu temu dolazi iz oblasti marketinga. Radovi koji se bave ovom tematikom, pored vremena sledeće kupovine, najčešće vrše predikciju i drugih vrednosti kao što su izbor brenda i predviđena količina.

Već postojeća rešenja u ovoj oblasti mogu se podeliti na dve veće celine. Prva grupa rešenja polazi od pretpostavke da iza svake kupovine stoji motiv, odnosno da je odluka koju je potrebno predvideti: *'da li kupiti?*'. Drugi pristup ne dovodi u pitanje okolnosti pod kojima je došlo do transakcije, već njih gleda iz perspektive vremenske distance između svake dve kupovine. Ovakav pristup za cilj ima da nađe odgovor na pitanje *'kada kupiti?*'.

A. Da li kupiti?

Kao što je već naglašeno, ovu grupu karakteriše motiv kupovine. Osnovna ideja ovog pristupa jeste ta da potrošač kupuje isključivo kada se za to javi potreba. Ova grupa bolje rezultate daje primenom na B2B model poslovanja. Razlog za ovo su racionalne, potrebom vođene kupovine koje su odlike ovakve vrste poslovanja. Jedan od predstavnika ove grupe obrađen je u [2]. Autori u ovom radu polaze od pretpostavke da se svaka kupovina obavlja kada zalihe padnu ispod određene granice. Modelovanje se vrši posebno za svaki segment (proizvod). Svakom uređenom paru kupac-proizvod dodeljuju se dve promenjive:

$\mathbf{CR^h}$ – stopa potrošnje kupca *h*
$\mathbf{INV^h_t}$ – stanje zaliha u trenutku *t* kupca *h*

Obe promenljive sa nekim koeficijentom utiču na verovatnoću kupovine. Stopa potrošnje ima pozitivan uticaj na verovatnoću i ideja je da kupci sa većom potrošnjom imaju više razloga da izvrše kupovinu. Stopa potrošnje kupca se računa u periodu incijalizacije i to: nalaženjem srednje vrednosti nedeljne potrošnje u ovom periodu. Nasuprot stopi potrošnje koja ima pozitivnu korelaciju sa verovatnoćom, stanje zaliha ima negativnu. Smatra se da kupci sa manjim zalihama imaju veću inicijativu da načine sledeću kupovinu. Vrednost ove promenljive računa se kao razlika kupljene količine i proizvoda proteklog vremena i stope potrošnje. Pored ovih, postoji i treća, podjednako značajna, promenljiva $\mathbf{CV^h_{tr}}$. Ona govori o vezanosti kupca za specifičan proizvod. Njena osnovna namena je upravljanje promenama u verovatnoći koje potiču od mogućnosti da kupac izabere proizvod drugog proizvođača.

Neke greške koje potencijalno nastaju ovakvim pristupom su sledeće:

- Stopa koja se izračuna u periodu inicijalizacije se nikad ne koriguje.
- Rast kupca, kao i sezonalnost proizvoda nigde nisu uključeni u model.

Jedna razlika ovog pristupa u odnosu na domen problema ogleda se u korišćenju $\mathbf{CV^h_{tr}}$ parametra. Kao što je već naglašeno, svrha ovog parametra je da unese konkurenciju u model. U suštini, to zapravo i nije neophodno. Od interesa za problem je svaka kupovina koja se desi, bez obzira na poreklo proizvoda. Razlog za ovo je potencijalno uticanje na kupca iz perspektive izbora dobavljača.

Pristup sličan ovome moze se naci u [3]. Autori u ovom radu objedinjuju izbor vremena kupovine i brenda u jedan model. Pretpostavka je da kupac najpre dolazi u situaciju gde je neophodno da izvrši kupovinu, a da nakon toga vrši izbor proizvođača. Kako je nama od značaja samo trenutak kada će kupovina biti načinjena, fokusiraćemo se samo na ovaj deo. U radu je definisana granica kupovine. Ova granica računa se preko dve promenljive:

$\mathbf{FREQ^i}$ -frekvencija kupovine
$\mathbf{LQ^i_t}$ – normalizovana količina poslednje kupovine

Slično kao što se u prethodnom radu stopa potrošnje kupca računa u periodu inicijalizacije i više se nikad ne menja, tako se i ovde frekvencija kupovina takođe izračuna samo u ovom periodu i važi za ceo životni vek kupca. $\mathbf{LQ^i_t}$ se koristi da unese efekte kupovina različitih količina proizvoda. Ova promenljiva se računa kao zadnje kupljena količina minus srednja kupljena količina u periodu inicijalizacije.

Granica kupovine se na dalje u radu koristi kao osnova za donošenje odluka o kupovini. Za svaki trenutak se svakom dobavljaču dodeljuje vrednost koja pokazuje 'poželjnost' tog dobavljača. Ova vrednost je zavisna od kolekcije marketinških promenljivih koje se u tom trenutku vezuju za svakog dobavljača ponasob. Do transakcija dolazi kada poželjnost nekog dobavljača pređe granicu neophodnu za kupovinu.

B. Kada kupiti?

Ovu grupu rešenja, kao sto je već napomenuto, odlikuje modelovanje vremena između dve kupovine. Generalni pristup zasniva se na nalaženju distribucije ili hazard funkcije koja najbolje opisuje među-transakcijska vremena, parametrizaciju ove distribucije/hazard funkcije za svaki par kupac-proizvod i onda primenu na konkretnu instancu.

Prvi pokušaj nalaženja distribucije viđen je u [4]. Ovde je iskorišćena eksponencijalna distribucija u cilju modelovanja. Negativna strana ovakvog pristupa je ta što, kod eksponencijalne distribucije, nikako nije moguće iskoristiti

informaciju da kupac još nije kupio proizvod. Odnosno nije moguće naći verovatnoću kupovine u narednom periodu pod uslovom da kupac još nije kupio. Jedan od ranijih pokušaja rešavanja ovog problema može se naći u [5]. Ovde autori za distribuciju biraju *Erlang-2*. Iako je ovako izabrana distribucija dala dobre rezultate, ona se ne može smatrati univerzalnom i naravno nije je moguće primeniti na svaki problem. Pregled karakteristike pojedinih distribucija koje su našle primenu u ovoj oblasti, kao i njihovih specifičnih slučajeva korišćenja dat je u [6]. Distribucije koje su u ovom radu obrađene su: *eksponencijalna, Erlang-2, Weibull, log-logistic* i *expo-power*.

Još jedan napredak na ovu temu viđen je u [7]. Većina radova koja polazi od drugog pristupa, odnosno modeluje vremena izmedju dve kupovine, koristi vreme zadnje kupovine kao početnu tačku. Kod ovakvog pristupa, isti model, izračunat u periodu inicijalizacije, se ponovo primenjuje svaki put nakon nove kupovine. Negativna strana ovakvog pristupa je ta što se istorijat kupovine ni u jednom trenutku ne uzima u obzir prilikom novog računanja. Pored ovog problema, ukoliko su diskretne mere vremena izražene u nedeljama ili mesecima, primenom ovakvih modela nije moguće predvideti dve ili više kupovina u istom periodu. Kao rešenje, autor predlaže korišćenje kalendarskog vremena umesto proteklog. Cilj je uključiti sve raspoložive informacije u model, od prve kupovine pa sve do trenutnog trenutka. Još jedan benefit korišćenja kalendarskog vremena je mogućnost dodavanja sezonalnosti. Da bi se ovo postiglo, koriste se četiri komponente: kalendarsko proteklo vreme, proteklo vreme između kupovina, funkcija kovarijanse i odstupanje od srednje vrednosti vremena između kupovina. Pored ovih komponenti, autor u svom modelu takođe dodaje *'at-risk'* promenjive za određivanje verovatnoća sukcesivnih kupovina kao i kupovina određenim danima. Posebna primena ovih promenljivih, pored kontrolisanja više kupovina u istom trenutku, je recimo dodeljivanje verovatnoća kupovinama u određenim trenucima. Na primer, u svetu veleprodaje, moglo bi biti od značaja postaviti verovatnoću kupovine subotama i nedeljama na nulu.

Bez obzira na izbor pristupa, važno je napomenuti da ni jedno od ovih rešenja nije univerzalno i da u velikoj količini zavise od specifičnog slučaja upotrebe. Ovo za posledicu ima da je prilikom primene nekog od rešenja na drugačiji skup podataka, neophodno izdvojiti dodatno vreme za istraživanje spesifičnog slučaja primene kao i parametrizaciju modela koji se koriste.

III. KONCEPT REŠENJA

Aplikacija je zamišljena kao Windows Desktop aplikacija čija je osnovna uloga predviđanje buduće potrošnje kupaca u sistemu veleprodaje. Naime, na osnovu istorije prethodnih kupovina, za svakog potrošača ponaosob je potrebno utvrditi da li će, i sa kojom verovatnoćom, u toku naredne sedmice od zadatog datuma (uglavnom današnjeg) potrošiti svu kupljenu količinu proizvoda. Ukoliko je predikcija za nekog kupca pozitivna, on će biti dodat na spisak potrošača kojima je potrebno preventivno reklamirati odgovarajući proizvod, a sve to u cilju održavanja konzistentnosti prodaje i eventualno, njenog povećanja. Ulazni parametri na koje korisnik ovog softverskog rešenja može uticati jesu datum u odnosu na koji je potrebno izvršiti predviđanje, kao i minimalna verovatnoća ostvarivanja predikcije u odnosu na koju se ona prihvata, odnosno odbacuje.

A. *Priprema podataka*

Na slici 1 prikazan je osnovni UML dijagram klasa aplikacije. Kao što je prethodno već napomenuto, s obzirom da podaci koji se analiziraju ne predstavljaju uobičajenu vremensku seriju, njih je potrebno najpre na odgovarajući način transformisati. Upravo iz tog razloga, prvi korak u procesu analize i predviđanja budućih vrednosti jeste *priprema podataka*.

Sagledavajući činjenicu da postoji više od jednog načina za obradu i transformaciju početnog skupa podataka u vremensku seriju, kreiran je interfejs *I_ARIMAPrepare*. Ideja je da se različiti metodi transformacije podataka enkapsuliraju u okviru posebnih klasa koje nasleđuju ovaj interfejs i implementiraju sve njegove osnovne funkcije. Osim što se omogućava ispitivanje efikasnosti različitih načina transformacije podataka, uvođenjem ovog interfejsa aplikacija postaje prilagodljiva širokom skupu ulaznih podataka, koji se mogu umnogome razlikovati od zabeleženih trenutaka kupovine potrošača.

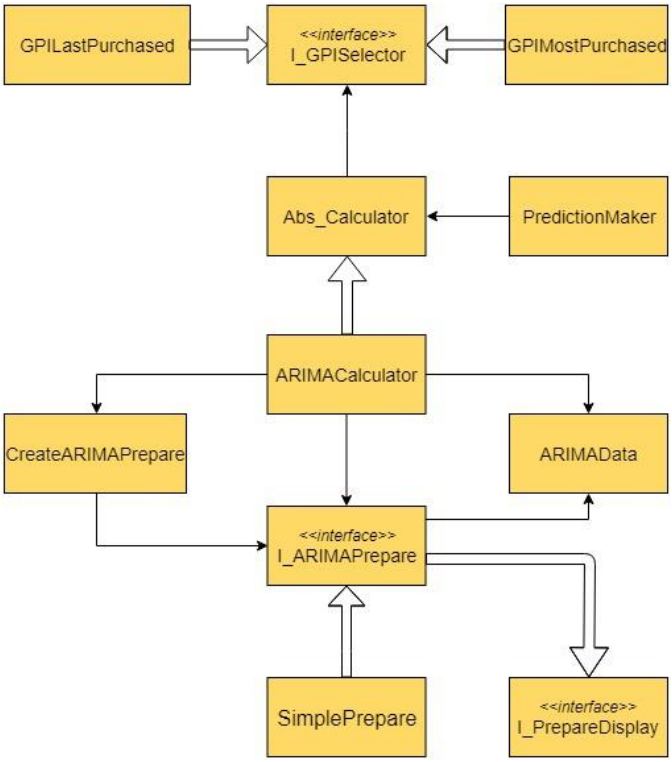
Metode za kreiranje regularne vremenske serije od početnog skupa podataka implementirane su u okviru klase *SimplePrepare*. Nakon učitavanja svih kupovina određenog potrošača do datuma unetog od strane korisnika aplikacije računa se prosečna dnevna potrošnja proizvoda. Prolazeći kroz niz kupovina, za svake dve kupovine se računa broj dana između njih, a zatim se deljenjem kupljene količine u prvoj sa brojem dana dobija prosečna dnevna potrošnja za period između te dve konkretne kupovine. Na ovaj način se od početnog skupa zabeleženih kupovina dobija regurlarna vremenska serija potrošnje proizvoda na dnevnom nivou. Ovaj proces je potrebno izvršiti za svaki proizvod koji potrošač kupuje, i dodatno, za svakog potrošača u sistemu. Osim ovog, direktno iz baze podataka učitava se još i niz prosečnih dnevnih potrošnji, ali na nivou proizvoda, odnosno dnevnih potrošnji proizvoda od strane svih potrošača u sistemu. Razlog za korišćenje ovog dodatnog niza je preciznija prognoza potrošnje kod potrošača sa oskudnom istorijom kupovina.

B. *Izračunavanje buduće potrošnje*

Nakon dobijanja regularne vremenske serije, može se krenuti sa njenom analizom i predikcijom budućih vrednosti pomoću ARIMA modela. Kao što je prethodno već naglašeno, sva izračunavanja vezana za modelovanje vremenske serije biće izvršena u R softverskom alatu.

Osnovna klasa u ovom delu procesa jeste apstraktna klasa *Abs_Calculator* koja slično kao interfejs *I_ARIMAPrepare*, omogućava lako proširenje aplikacije u budućnosti novim metodama za analizu vremenske serije. Trenutno

implementirana metoda korišćenjem ARIMA modela enkapsulirana je u okviru klase *ARIMACalculator*, koja kao što se sa slike 1 može primetiti, nasleđuje apstraktnu klasu *Abs_Calculator*. Uzimajući u obzir kompleksnost izračunavanja i količinu podataka koja se obrađuje, radi optimizacije čitavog procesa u sklopu *ARIMACalculator*-a kreirane su tri niti koje paralelno vrše obradu za pojedinačne potrošače. Funkcija ove klase je takođe i pravovremeno ažuriranje interfejsa radi informisanja korisnika aplikacije o količini obavljene i preostale analize podataka.



Slika 1. Osnovni UML dijagram klasa

Uzimajući u obzir činjenicu da se sama predikcija budućih vrednosti izvršava u R programskom jeziku, neophodno je bilo izvršiti integraciju tog softverskog alata i Windows Desktop aplikacije. To je jedna od osnovnih funkcija *PredictionMaker* klase koja u odgovarajućem trenutku poziva na izvršenje R skriptu sačinjenu od neophodnih naredbi za dobijanje prognoze.

Ulazni parametri R procedure jesu niz prosečnih dnevnih potrošnji za konkretnog potrošača, broj dana odnosno elemenata niza prosečnih dnevnih potrošnji konkretnog proizvoda od strane svih potrošača, kao i datum u odnosu na koji se vrši prognoza. Pozivanjem odgovarajućih R funkcija, uključujući i osnovnu *forecast* metodu, kao izlaz iz R skripte dobijamo prosečnu dnevnu potrošnju za narednih nedelju dana, na nivou konkretnog potrošača.

Na osnovu poslednje zabeležene kupljene količine konkretnog proizvoda, sa određenom verovatnoćom se zaključuje da li će potrošač u toku naredne nedelje potrošiti sve zalihe tog proizvoda. Ukoliko je to slučaj, onda se shodno tome taj potrošač dodaje na listu onih kojima je taj proizvod potrebno pravovremeno izreklamirati.

IV. Rezultati

Aplikacija je testirana nad realnim podacima proizvođača medicinske opreme.

A. Podaci

Podaci sa kojima smo radili sastoje se od preko tri miliona transakcija prodaje prikupljenih u periodu od dve godine i sedam meseci. Set čine nešto više od 9.000 jedinstvenih kupaca od kojih je oko 7.000 njih imalo ponovljene kupovine. Sa druge strane za vreme ovog perioda prodato je oko 6.300 jedinstvenih proizvoda. Za potrebe testiranja, predikcije su se vršile nedeljom i to za period od narednih nedelju dana. Prosečan broj transakcija na nedeljnoj bazi, u test periodu, bio je približno 23.000. Vremenski period kupovina bio je podeljen na:

1. Trening i validacioni set – 50%
2. Test set – 50%

Razlog za ovakvom podelom javio se iz podrebe za neuobičajeno velikim test setom. Naime, s obzirom da se kao izlaz iz sistema očekuju sve predikcije kupovine, a ne samo one koje se odnose na dobavljača čije podatke koristimo, bilo je neophodno odstraniti kupce i predikcije kupovina koje se više nikad nisu ponovile. Za ovakve slučajeve, vodimo se pretpostvakom da su se kupovine izvršile kod drugog dobavljača ili da je kupac našao neku drugu alternativu proizvodu. Kako ne možemo biti sigurni kada se kupovina u ovoj grupi desila kod drugog dobavljača, moramo je odstraniti iz statistike. Da bi bili sigurni da se kupovina nije desila, test period mora da bude dovoljno veliki da ukloni svaku sumnju.

B. Naivna metoda

Za potrebe poređenja korišćena je verzija starog sistema, u kome je bila implementirana naivna metoda dobijanja prognoze. Ova metoda trenutak sledeće kupovine nalazila je računanjem tri parametra za svaki par kupac-proizvod: srednje, minimalno i maksimalno vreme između dve kupovine. Pomoću ovih parametara vreme sledeće kupovine dobijalo se dodavanjem srednjeg vremena između dve kupovine na trenutak zadnje kupovine, pod uslovom da nema većih odstupanja od minimalnog i maksimalnog vremena. Dozvoljena razlika između ova dva parametra dobijana je pravljenjem balansa između preciznosti predikcija i broja predikcija koju je potrebno načiniti. Ukoliko bi se koristila velika razlika, preciznost bi drastično opala. Ukoliko bi ta razlika pak bila previše mala, ne bi se načinilo dovoljno predikcija za sledeću nedelju. Ovakvo rešenje davalo je prilično loše rezultate, srednja preciznost se iz nedelje u nedelju kretala oko 6,9% dok je pokrivenost slučajeva (broj tačnih predikcija / broj ostvarenih kupovina) iznosila 0,53%.

Postoji više razloga zašto je ovakav pristup davao loše rezultate, a među najvažnijima su:

1. Prethodno kupljena količina uopšte nije uzimana u obzir prilikom izračunavanja
2. Favorizuju se kupci sa manjim brojem kupovina

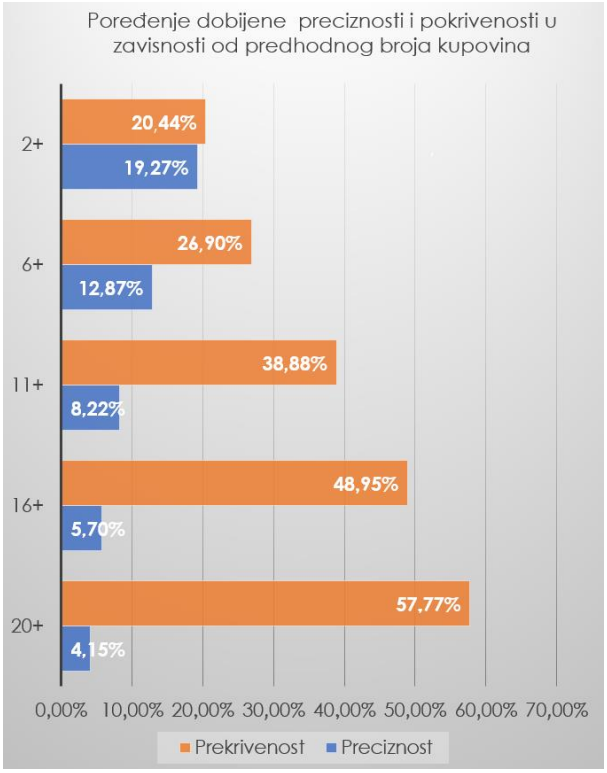
Razlog zašto je dolazilo do favorizovanja kupaca sa manjim brojem kupovina je taj što je, pri velikom broju kupovina, razlika između minimalnog i maksimalnog vremena između dve transakcije statistički mogla samo da se povećava. Ovakve predikcije bi pre bile odbačene kao neopouzdane što je suprotno željenom ponašanju.

C. *Rezultati testiranja*

Kao što je već spomenuto za računanje preciznosti predikcija, korišćene su samo kupovine koje su se makar jednom realizovale u test periodu. Kada je reč o pokrivenosti realizovanih kupovina, iz ukupnog broja transakcija izuzete su one koje se kao par kupac-proizvod javljaju po prvi ili po drugi put. Razlog za ovo je delimična nepredvidljivost ovakvih kupovina.

Rezultati su dati na na slici 2. Može se uočiti da za parove kupac-proizvod postoji pozitivna korelacija između broja transakcija i preciznosti predikcije. Kada bi se predikcija vršila za sve moguće parove, preciznost bi iznosila 20,44%, dok za parove koji imaju više od 20 načinjenih kupovina, ta vrednost dostiže skoro 60%. Još jedna značajna stvar je da uvođenjem jednog ovakog sistema, preciznost bi se samim delovanjem samo još vise povećala.

Nasuprot preciznosti, pokrivenost realizovanih kupovina ima negativnu korelaciju sa povećanjem broja neophodnih transakcija za kreiranje predikcije.



Slika 2. Poređenje dobijene preciznosti i pokrivenosti u zavisnosti od prethodnog broja kupovina

D. *Performanse*

Celokupna obrada podataka rađena je na računaru sa procesorom marke Intel model i7-6700T i 8GB ram memorije. Za obradu je bilo neophodno između 15 i 17 sati. Kompleksnost algoritma je u lineranoj zavisnosti sa brojem parova kupac-proizvod, a ovo ima povoljne ishode na skalabilnost. Takodje rešenje se može u velikoj meri paralelizovati i ima elemente računice koja potencijalno može da se izvršava na grafičkom procesoru, čime bi se dodatno povećale performanse.

V. Zaključak

Modeli vremenskih serija predstavljaju vrlo moćno sredstvo za predviđanje budućih vrednosti i donošenje odluka u različitim oblastima života i rada: ekonomiji, poljoprivredi, industriji, medicini, itd. U praksi se pokazalo da veliki broj pojava zavisnih od vremena mogu da se modeliraju pomoću stohastičkih procesa. Rasprostranjenost i atraktivnost ovih modela je posledica njihove same strukture koja je lako razumljiva i prilično intuitivna. Za razliku od nekih drugih modela koji razmatraju vezu između dve ili više različitih pojava, modeli vremenskih serija, uključujući i ARIMA model, ispituju uticaj istorijskih vrednosti jedne pojave na njenu sadašnju i buduću vrednost. Ovakav pristup omogućava proučavanje ponašanja date pojave u vremenu i daje dobre rezultate, naročito ukoliko je dostupan veliki broj istorijskih podataka.

Naravno, kao i svi modeli, ni ARIMA model, korišćen u ovom radu, ne predstavlja savršen prikaz stvarnog stanja, ali uprkos tome, ovaj model i dalje omogućava brz i efikasan postupak koji sa dosta preciznosti daje prognozu budućih vrednosti.

Abstract

Time series analysis is to explain correlation and the main features of the data in chronological order by using appropriate statistical models. It’s being used in various aspects of life and work, as well as in forecasting future product demands, service demands, etc. The most common

type of time series data is the one whose observations are taken in equally distributed time intervals (daily, weekly, monthly, etc.). However, in this paper, we analyze unusual time series that represents product purchase moments. Thus there isn't regular obesrvation periods, this irregular time series must be transformed in some way before traditional methods of analysis can be applied. After data transformation is complete, next step is modeling nonstationary time series using commonly known ARIMA model, which has been chosen for accentuated seasonality and fairly easy and successful forecasting process. Goal of this analysis is timely product advertising to a customer in order to increase sale.

Time Series Analysis: Forecasting wholesale future demands

Arhitektura i implementacija softverskog sistema za fleksibilno sprovođenje korisnički definisanih anketa

Ognjen Milošević, Marko Mišić, *Member, IEEE*, Jelica Protić

***Apstrakt*—Sprovođenje korisnički definisanih anketa je čest proces u današnjem poslovanju. Bilo da su u pitanju akademske ili marketinške potrebe, postavlja se pitanje na koji način ankete sprovesti tako da se na brz i jednostavan način dopre do ispitanika bez suvišnih koraka koji bi ga eventualno odvratili od popunjavanja zadatog upitnika. Sa druge strane, prikupljanje podataka treba da bude jednostavno i sa stanovišta onoga ko ispituje neku temu, bez potrebe za korišćenjem komplikovanih sistema. Rasprostranjenost mobilnih uređaja u današnjem svetu olakšava sprovođenje anketiranja sa strane ispitanika, a u radu su prikazani arhitektura i implementacija jednog sistema za fleksibilno sprovođenje korisnički definisanih anketa. Sistem se sastoji od mobilne, veb i serverske aplikacije, a ceo proces se sprovodi bez korišćenja klasične baze podataka i sa relativno skromnom upotrebom resursa.**

***Ključne reči*—korisničke ankete; veb programiranje; mobilna aplikacija.**

I. Uvod

SVE veća dostupnost Interneta u poslednje dve decenije je značajno promenila način sprovođenja anketa (upitnika, intervjua). Anketiranje je poseban metod prikupljanja informacija pomoću kojeg se dolazi do podataka o stavovima i mišljenjima ispitanika na zadatu temu. Umesto tradicionalnih načina kao što su anketa licem u lice, telefonska anketa, anketa na papiru, sve je više zastupljeno anketiranje elektronskim putem [1].

Anketiranje elektronskim putem se danas najčešće sprovodi putem Interneta. Bilo kakvo ozbiljnije ispitivanje javnog mnjenja bez upotrebe modernih tehnologija je danas gotovo nezamislivo. Ovakav način anketiranja štedi vreme, energiju, kao i materijalne resurse anketara. Takođe, s obzirom na dostupnost interneta danas, ova vrsta anketiranja pruža velike mogućnosti za ispitivanje statistički značajnog uzorka, jer se ispitanici lakše odlučuju da posvete vreme ovakvoj vrsti upitnika zbog njegove jednostavnosti.

Razvoj interneta je najpre doneo elektronske upitnike putem veba i računara. Međutim, sa povećanjem mogućnosti pametnih telefona, teži se potpunoj zameni računara. Pametni telefoni danas pružaju korisniku mogućnost da gotovo svaki posao, za koji je do skoro računar bio neophodan, obave u bilo kom trenutku i na bilo kom mestu.

Mobilna aplikacija za anketiranje je iz tog razloga sagledana kao vrlo praktičan način anketiranja. Osim dostupnosti na svakom mestu, mobilni telefon ima i druge prednosti, kao što je mogućnost skeniranja različitih kodova putem kamere (bar kod, QR kod). Pomenute prednosti mobilne aplikacije za anketiranje motivisale su projektovanje i izradu softverskog sistema koji kroz mobilnu aplikaciju u samo nekoliko koraka omogućava pristupanje anketi preko QR koda, popunjavanje i slanje odgovora na server gde će se oni čuvati za dalju upotrebu.

Da bi softverski sistem bio potpun, osim pomenute mobilne aplikacije, bilo je potrebno realizovati i veb aplikaciju za administriranje anketa. Sa veb aplikacije moguće je kreiranje novih anketa, definisanje kodova za pristup aneketi, ali i pregled statistike za postojeće ankete, kao i generisanje izlaznog fajla sa prikupljenim odgovorima u tabelarnom formatu radi lakšeg pregleda odgovora. Treći deo ovog sistema je serverska aplikacija, koja služi za manipulaciju podacima kao što su čuvanje anketa, provere kodova sa mobilne aplikacije, slanje odgovarajuće ankete ka mobilnoj aplikaciji i slično. Da bi sistema bio skalabilan i fleksibilan za korišćenje od strane, kako anketara, tako i ispitanika, zamišljen je da bude sa malim režijskim troškovima (eng. *lightweight*) i naporom za korišćenje. U nastavku rada će biti data motivacija za njegovu implementaciju i opisane donesene projektne odluke.

Rad je podeljen na nekoliko sekcija. U okviru drugog poglavlja data je funkcionalna specifikacija sistema sa osvrtom na bitne detalje za implementaciju. Treće poglavlje kratko opisuje korišćene tehnologije, dok su u četvrtom poglavlju opisane arhitektura i implementacija sistema. U finalnom poglavlju je dat kratak zaključak i pravci za dalji razvoj.

II. Funkcionalna specifikacija

Cilj ovog rada bilo je kreiranje softverskog sistema za sprovođenje korisnički definisanih anketa. Sistem je trebalo projektovati tako da obuhvata sve bitne aspekte: od kreiranja ankete, preko administriranja ankete, do sakupljanja odgovora uz naglašenu jednostavnost upotrebe i što je moguće manju upotrebu resursa za smeštanje podataka.

Ognjen Milošević – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar Kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: milosevic.etf@gmail.com).

Marko Mišić – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar Kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: marko.misic@etf.bg.ac.rs).

Jelica Protić – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar Kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: jelica.protic@etf.bg.ac.rs).

Iz tog razloga sistem je zamišljen iz tri dela, kao distribuirana aplikacija, koji rade kao jedna celina. Delovi koji čine ovaj sistem, kao i skup njihovih funkcionalnosti navedeni su u nastavku:

- Veb aplikacija za kreiranje i administriranje anketa;
- Android aplikacija za popunjavanje anketa i slanje odgovora na server;
- Serverska aplikacija koja posreduje između dve prethodno navedene, distribuira ankete do korisnika i čuva sve potrebne informacije i odgovore.

Nadalje biće detaljnije opisani zahtevi za svaku od pomenutih aplikacija.

A. Veb aplikacija

Zahtev koji je postavljen u vezi sa veb aplikacijom je jednostavan interfejs za administriranje korisnički definisanih anketa od strane korisnika koji sprovodi anketu. Pod administriranjem se podrazumevalo kreiranje same ankete, generisanje kodova za pristup anketi, kao i pregled postojećih anketa. Potrebno je bilo omogućiti generisanje kako tekstualnih, tako i generisanje grafičkih kodova, poželjno QR (eng. *Quick Response*) kodova.

Prilikom kreiranja ankete administrator unosi naziv ankete, opis, broj kodova koji će biti generisani, datum i vreme isteka ankete, kao i pitanja koja mogu biti različitih tipova. Podržana su tri najčešće korišćena tipa pitanja u anketama zatvorenog tipa: pitanje sa jednostrukim izborom, pitanje sa višestrukim izborom i Likertova skala. Kod Likertove skale su dati ponuđeni odgovori u opsegu od 1 do 5.

Što se pregleda i administracije postojećih anketa tiče, tu su podaci o broju poslatih odgovora do trenutka proveravanja, broju generisanih kodova za izabranu anketu, datumu kreiranja i isteka, mogućnost da se kreiraju dodatni kodovi za pristup anketi i da se generiše izveštaj u MS Excel (XLSX) formatu od trenutno primljenih odgovora.

B. Mobilna aplikacija

Mobilna aplikacija treba da pokriva tri osnovne funkcionalnosti. To su učitavanje QR koda za pristup anketi koje se izvršava preko kamere, popunjavanje odgovara na postavljena pitanja koja server vraća nakon slanja koda na serversku stranu i slanje popunjenih odgovora na server.

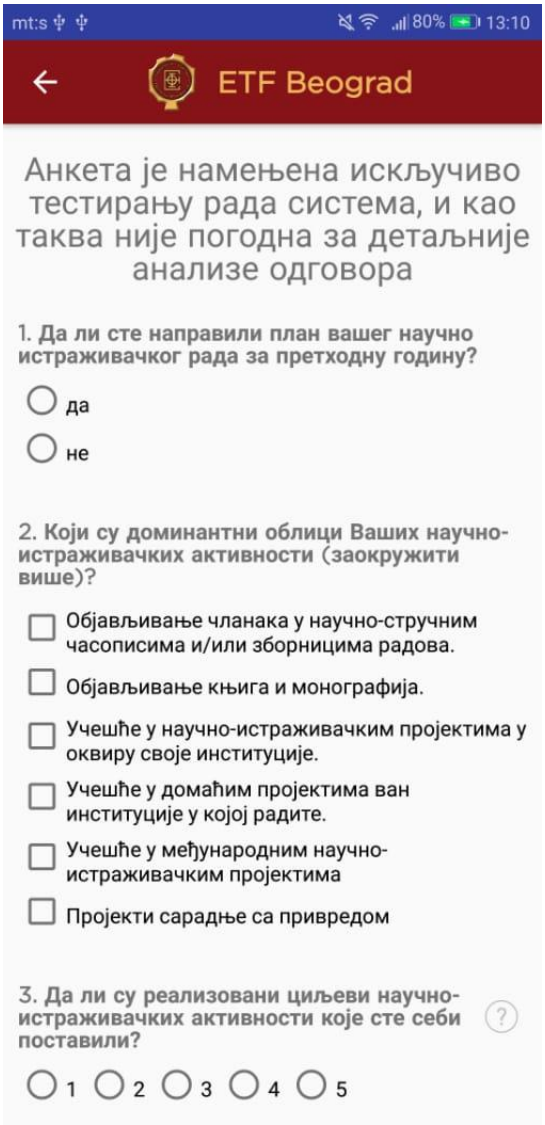
Jednostavnost upotrebe se pre svega ogleda u odsustvu bilo kakve forme registracije ili autentifikacije korisnika. Dakle, dovoljno je da korisnik instalira aplikaciju na pametni uređaj, pokrene je, unese dobijeni kod i može odmah pristupiti popunjavanju ankete, kao što se može videti na Slici 1.

C. Serverska aplikacija

Zadatak serverske aplikacije je da opslužuje dve prethodno pomenute aplikacije podacima sa servera i skladišti podatke od interesa. U okviru serverske aplikacije odvijaju se sve obrade nad podacima, kao što je provera validnosti QR koda i slanje na mobilnu aplikaciju odgovarajuće ankete ukoliko je kod validan i anketa aktivna. Takođe, serverska aplikacija vrši prijem podataka sa mobilne aplikacije u vidu odgovora na anketu i čuvanje istih.

Čuvanje ankete koja se kreira preko veb aplikacije takođe se vrši preko serverske aplikacije, ali i druge obrade kao što su invalidacija koda nakon potvrde završetka ankete, inkrementiranje broja dosadašnjih odgovora na odgovarajuću anketu, generisanje novih kodova.

Zbog jednostavnosti i fleksibilnosti, zahtevano je da na serverskoj strani ne postoji klasična baza podataka, već da se podaci čuvaju u odgovarajućem međuformatu koji se lako može izvesti u tabelarni format pogodan za dalju obradu. U tom smislu, čuvanje podataka o isteklim anketama nije ni od kakvog interesa za sam sistem.



Sl 1. Stranica za popunjavanje ankete u okviru mobilne aplikacije

III. KORIŠĆENE TEHNOLOGIJE

S obzirom na zahteve za realizacijom distribuiranog sistema koji se sastoji od tri zasebne aplikacije koje se izvršavaju u tri različita okruženja, pažljivo se pristupilo odabiru korišćenih tehnologija za njihovu izradu.

Za programiranje mobilne aplikacije za Android uređaje, postojala je dilema između upotrebe programskog jezika Java

i njegove nadogradnje Kotlin koja pruža nešto jednostavniji i koncizniji način pisanja mobilnih aplikacija [2]. S obzirom na bogatiji izbor biblioteka za različite obrade, platformsku nezavisnost, činjenice da je programski jezik Java jedan od najzastupljenijih programskih jezika, Java je izabrana za realizaciju svih bitnih aspekata sistema.

Kada je reč o razvoju internet aplikacija, tendencije su takve da se sve više prelazi na skriptne jezike, bazirane na *Javascript*-u, kao i prelaz na SPA (eng. *Single Page Application*) aplikacije, kada one zadovoljavaju korisničke zahteve. SPA, su aplikacije koje ne zahtevaju ponovno očitavanje stranica tokom upotrebe, jer se većina resursa učitava jednom tokom životnog ciklusa aplikacije [3]. Manipulacija podacima koji se šalju na server i uzimaju sa servera su jedina očitavanja koja se očekuju kasnije u toku rada. Iz tog razloga, za veb aplikaciju realizovanu u ovom radu, SPA je veoma pogodan i efikasan izbor koji je realizovan putem *Angular* radnog okvira i *Typescript* jezika.

U ovom softverskom sistemu, razmena podataka između aplikacija realizovana je preko HTTP protokola, a što se tiče izbora servisa za API pozive, prvi izbor u izradi ovog rada su bili REST (eng. *Representational state transfer*) servisi, a razlozi za to su mnogobrojni.

Nezavisnost između klijentske i serverske aplikacije, uz komunikaciju jedino preko zahteva i odgovora je jedna od odlika REST servisa koja je bila pogodna za ovakvu arhitekturu sistema, s obzirom da jedna serverska aplikacija opslužuje dve klijentske. REST servisi su realizovani kroz Java programski jezik i radni okvir *Spring boot*. Razlozi za to su jednostavnost prilikom podešavanja okruženja i pokretanja aplikaciije na serveru, kao i dovoljan skup funkcionalosti i alata da se pokriju svi zahtevi iz ovog projektnog zadatka.

Za razmenu i čuvanje podataka je odabran JSON format. JSON format je čitljiv ljudima, ima izraženu hijerarhiju, čime se mogu predstaviti vrednosti unutar objekata, može se parsirati i koristiti iz mnogih programskih jezika. Alternativa je bila upotreba XML formata, ali JSON daje dosta kraći kod, pa je samim tim lakši za „ručno“ pisanje i čitanje, a najveća prednost koju treba izdvojiti za kreiranje ovog sistema je to što je za XML potreban odgovarajući parser da bi se koristio u skriptnim jezicima, dok se JSON kao takav može koristiti u skriptnim jezicima kao što je *Typescript* u kom se u ovom slučaju koristi [4].

IV. Opis rešenja

Ovo poglavlje je posvećeno detaljnijem objašnjenju realizacije sistema. Sistem je bliže predstavljen prolaskom kroz neke od najvećih problema prilikom realizacije u narednim podglavama i objašnjenje njihovih rešenja.

A. Format JSON fajlova

Sa odlukom da kompletan softverski sistem realizuje bez klasične baze podataka i da se svi podaci čuvaju u tekstualnim fajlovima u JSON formatu, bilo je potrebno pažljivo osmisliti u koliko fajlova smestiti sve podatke, kako ih rasporediti, ali i kako ih održavati i dopunjavati.

Prilikom kreiranja ankete, formira se fajl sa identifikacionim brojem ankete kao nazivom, u koji se upisuju pitanja i ponuđeni odgovori. Format fajla za čuvanje ankete prikazane na Slici 1. prikazan je na Slici 2.

```
{
   "survey":{
      "id":"11",
      "description":"Anketa je namenjena isključivo
testiranju rada sistema, i kao takva nije pogodna za
detaljnije analize odgovora",
      "numOfQuestions":"3",
      "questions":[
         {
            "num":"1",
            "text":"Da li ste napravili plan vašeg
naučno istraživačkog rada za prethodnu godinu?",
            "type":"single",
            "answers":[
               "da",
               "ne"
            ]
         },
         {
            "num":"2",

            "answers":null
         },
      ]
   }
}
```

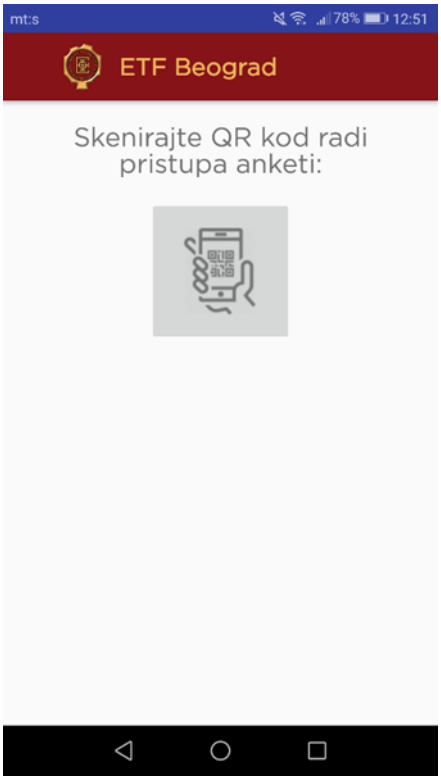
Sl. 2. Primer JSON fajla za čuvanje anketa i pitanja

Osim prikazanog fajla, pri kreiranju ankete se ažuriraju i postojeći fajlovi u kojima se čuvaju osnovni podaci o svim postojećim anketama, kao i podaci o kodovima za anketu. Fajl u kojem se čuvaju odgovori se takođe kreira prilikom kreiranja ankete, sa praznom listom JSON objekata i ažurira se prilikom slanja svakog odgovora na server. U njemu se osim odgovora na pitanja čuva i odgovarajući kod sa kojim je pristupljeno anketi. Objekat za odgovor na svako pitanje ima isti format, radi lakšeg formiranja izlazne tabele, a u zavisnosti od tipa pitanja neka polja u objektu ostaju prazna, tačnije imaju *null* vrednost.

B. *Skeniranje kodova*

Da bi skenirali kod preko Android aplikacije potreban, ali ne i dovoljan uslov je pristup kameri telefona koji je omogućen dodavanjem odgovarajuće linije koda u *AndroidManifest.xml* fajlu u sklopu aplikacije. Osim toga, potreban je i alat koji može da skenira QR kodove i da ih pretvori u odgovarajući link ili niz karaktera. Kako je sama realizacija ovakvog alata veliki posao, iskorišćena je već postojeća aplikacija *Barcode Scanner* kojoj se pristupa preko naše aplikacije [5]. Naravno, ovo nije jedina aplikacija za ovu namenu, ali kao besplatna aplikacija, pogodna za integraciju unutar drugih aplikikacija, pokazala se kao efikasno rešenje.

Skeniranje se pokreće pritiskom na odgovarajuće dugme u okviru forme mobilne aplikacije (Slika 3.), a zatim se u posebnoj metodi obrađuje rezultat skeniranja. U zavisnosti od koda rezultata, ili se korisniku ispisuje poruka o neuspešnom skeniranju i traži novi pokušaj, ili se sa dobijenim kodom poziva metoda za dohvatanje ankete, čiji je argument učitani kod, u kojoj će biti poslat zahtev serveru za dobijanje ankete koja odgovara datom kodu.



Sl. 3. Ekran mobilne aplikacije u okviru koga se vrši skeniranje kodova

C. *Tipovi REST servisa i njihova upotreba*

Postoji više različitih tipova HTTP zahteva koji se mogu slati ka serveru, u zavisnosti od namene servisa. Kod REST API servisa uobičajno je da se koriste *get*, *put*, *post* i *delete* metode [6].

Za skup funkcionalnosti koje su bile potrebne za realizaciju ovog softverskog sistema, bilo je dovoljno korišćenje *get*, *post* i *put* moetoda te će samo one u ovom radu biti detaljnije objašnjene, a zatim će biti izneti primeri korišćenja ovih zahteva u softverskom sistemu.

Get metode namenjene su isključivo čitanju podataka sa serverske strane. Koriste se za čitanje određenog podatka ili cele kolekcije podataka. Zbog toga mogu imati parametre unutar putanje, koji mogu biti identifikator pojedinačnog objekta iz kolekcije koji će biti vraćen ili neki drugi kriterijum po kom će se filtrirati kolekcija da bi se dobio odgovarajući odgovor od servera. U skladu sa tim, u ovom projektu su *get* metode korišćene za pronalaženje ankete preko učitanog koda gde je kod parametar u zahtevu, kao i za vraćanje svih anketa za ispis na stranici sa anketama - zahtev bez parametara i vraćanje odgovora za određenu anketu preko identifikacionog broja gde je *id* parametar u zahtevu.

Post i *put* metode služe za umetanje elementa u postojeće kolekcije ili za kreiranje kolekcija entiteta. Po preporuci se *post* metode koriste za kreiranje novih entiteta ili kolekcija, dok *put* metode služe za izmene na postojećim. Shodno tome, *put* metode se mogu pozvati slično kao *get*, sa parametrima unutar putanje, dok je kod *post* metoda najčešće praksa da osim opcionih parametara unutar putanje, postoji i određeni entitet umetnut u zahtev koji se prosleđuje ka serveru.

Post metode su korišćene za pozive serveru prilikom kreiranja nove ankete i prilikom slanja odgovora na server, gde se prosleđuju kompletni entiteti. *Put* metode su iskorišćene kod metoda u kojima se menjaju postojeći entiteti, a to su metode za generisanje novih kodova za pristup anketi i metoda za promenu vremena isteka ankete. Sve metode su napisane uz korišćenje odgovarajućih *Spring boot* anotacija.

D. *Dinamičko kreiranje komponenti na veb stranici*

Kod stranice za kreiranje anketa na veb aplikaciji, postojala je potreba za dinamičkim kreiranjem komponenti, s obzirom da nije unapred određen broj pitanja u anketi, niti broj ponuđenih odgovora za pojedinačna pitanja.

Stoga se incijalno se kreira komponenta koja sadrži prazan kontejner na koji se mogu dodvati odgovarajuće komponente, da bi se kasnije korišćenjem klase *ViewContainerRef* kreirale i dodavale komponente na njega. Na gotovo identičan način je rešen i problem dodavanja komponenti za odgovore na komponentu za pitanja. Sve ovo je izvedeno kroz mogućnosti koje pruža radni okvir *Angular* [7].

E. *Izmene postojećih JSON fajlova*

Za manipulaciju JSON fajlovima iz serverske Java aplikacije korišćene su klase *JSONParser*, *JSONObject* i *ObjectMapper*.

Prve dve pomenute klase su iz *org.json.simple* paketa. *JSONParser* klasa služi za parsiranje JSON teksta u Java objekat koji se (ukoliko je JSON tekst validan) može eksplicitno konvertovati u objekat tipa *JSONObject*. *JSONObject* klasa nasleđuje *HashMap* klasu, *java.util* paketa. Za razliku od standarnog funkcionisanja heš mape, ova klasa ima i dodate metode za konvertovanje parova ključ-vrednost u JSON stringove, što je čini pogodnom za potrebne operacije pristupanja postojećim JSON objektima i generisanja izmena na njima.

Što se tiče klase *ObjectMapper*, ona pripada *com.fasterxml.jackson.databind* paketu, njena namena je čitanje i pisanje JSON formata, kako iz Java entiteta, tako i iz samih JSON fajlova, što je korišćeno prilikom dodavanja odgovora u postojeći fajl. S obzirom na potrebu da se odgovori umetnu u postojeću listu u okviru JSON objekta, bilo je potrebno prvo pristupiti toj listi, što je urađeno odmah nakon parsiranja i konvertovanja objekta u *JSONObject*. U tu listu nije moguće umetnuti objekat onakav kakav je prosleđen kroz zahtev serverskoj aplikaciji, već je neophodno formirati odgovarajući JSON objekat. Tako se kreiran novi JSON objekat u koji se podaci upisuju kao u mapu. Kada se taj objekat doda u listu, potrebno je samo ažurirani objekat ispisati preko mapera. Takođe, prilikom dodavanja odgovora invalidira se kod koji je poslala klijentska aplikacija i vraća joj se odgovor da je čuvanje odgovora uspešno završeno.

F. Generisanje izlaza u XLSX formatu

Jedna od fukncionalnosti ovog softverskog sistema je generisanje izlaza u XLSX formatu, tačnije ispis tabele iz JSON fajla sa odgovorima za odgovarajuću anketu, kako bi bili jednostavniji za dalju obradu.

Za parsiranje i ispisivanje samog fajla korišćena je *xlsx* biblioteka, dok je za čuvanje fajla na korisničkoj strani korišćena *file-saver* biblioteka.

Same fajlove u kojima su čuvani odgovori je bilo neophodno dodatno obraditi kako bi se dobio odgovarajući izlaz. Razlog leži u tome što se metoda *json_to_sheet* nije pokazala kao dobro rešenje za konvertovanje niza složenijih objekata koji sadrže nizove, te je u petlji formiran niz prostih objekata u kojima su sva polja tipa *string*, kako bi ih ispisao na adekvatan način u XLSX fajlu.

V. Zaključak

Korišćenjem pametnih telefona ili tablet računara za popunjavanje anketa, može se uprostiti kako kontrola pristupa anketi pomoću koda, tako i samo ispitivanje, koje se obavlja u par jednostavnih koraka i što je možda još bitnije uz vrlo malo utrošenog vremena. Veb aplikacija za kreiranje i administraciju anketa je realizovana pomoću radnog okvira *Angular*, veoma je intuitivna, jednostavna za korišćenje, a zahvaljujući odluci da se realizuje kao SPA i performanse su na zadovoljavajućem nivou, te i deo posla oko administracije ne zahteva previše vremena. Kada je reč o serverskoj aplikaciji, takođe su postignuti zadovoljavajući rezultati. Pri testiranju sa lokalnog servera, serverska aplikacija je efikasno opsluživala obe aplikacije, te nije bilo značajnijeg kašnjenja prilikom pozivanja servisa i čekanja odgovora sa servera.

Postoje dva glavna pravca za proširenje i poboljšanje ovog sistema. Jedan se tiče aspekta bezbednosti. Prilikom testiranja na lokalnom serveru, nije realizovana autentifikacija prilikom poziva metoda, te su zahtevi ka serveru dostavljani bez kredencijala u zahtevima. Sa proširenjem primene van lokalnog servera, bezbednosni mehanizmi bi morali da postoje. Slično važi i za veb aplikciju, u kojoj takođe u nekoj od narednih verzija treba zahtevati autentifikaciju korinika pre pristupa stranicama za administriranje.

Drugo unapređenje bi se odnosilo na uvođenje kompletne baze podataka na serverskoj strani aplikaciji. U tom slučaju, dalji razvoj bi išao ka dodavanju komponente za analizu rezultata, što se u ovom slučaju želelo izbeći. Za testiranje ovakvog sistema, kao i za rad sa umerenim brojem ispitanika, JSON fajlovi su se pokazali kao dovoljno obuhvatni i efikasni za čuvanje svih podataka, međutim za realne primene ovakve aplikacije sa velikim brojem ispitanika i analizom rezultata, rad bez baze podataka je gotovo nezamisliv. Kao međurešenje, takođe bi se moglo razmisliti o uvođenju neke nerelacione baze podataka, poput MongoDB, za smeštanje samih JSON fajlova, umesto korišćenja fajl sistema.

Zahvalnica

Ovaj rad je delimično finansiran od strane Ministarstva prosvete, nauke i tehnološkog razvoja Republike Srbije, projekti broj III44009 i TR32047, 2019. Autori izražavaju zahvalnost na finansijskoj podršci.

Abstract

Conducting user-defined surveys is a common process in modern business. Whether academic or marketing needs are concerned, the question arises as to how to conduct surveys in a quick and easy way. Respondents need to be reached without any redundant steps that might deter them from filling in the given questionnaire. On the other hand, data collection should be easy from the point of view of interviewer who examines a topic, without the need to use complicated systems. The prevalence of mobile devices in modern world makes thing easier for the respondents to fill in the survey. The paper presents an architecture and implementation of a system for the flexible implementation of user-defined surveys. The system consists of a mobile, web and server application, and the entire process is implemented without the use of a database and relatively modest resource use.

Architecture and Implementation of Software System for Conducting User-Defined Surveys

Ognjen Milošević, Marko Mišić, Jelica Protić

Jedno rešenje daljinskog upravljanja STB platforme putem REST protokola

Milan Gvero, Ilija Bašičević, Nikola Špirić

***Apstrakt*—Ovaj rad predstavlja jedno rešenje daljinskog upravljanja set top box (STB) platforme putem REST protokola. Rešenje je realizovano za već postojeću DTV aplikaciju te predstavlja njeno unapređenje. Rešenje omogućava korisniku da nastavi gledanje sadržaja sa mobilnog telefona, tableta i sličnih uređaja na STB uređaju tako što korisnik prevuče prstom na gore (eng. swype) dok konzumira multimedijalni sadržaj. Multimedijalni sadržaj se tada pauzira na telefonu, a nastavlja da se reprodukuje na STB uredjaju. Takođe rešenje dodaje podršku za simulaciju daljinskog upravljača, stoga korisik može da kontroliše STB putem mobilnog uređaja.**

***Ključne reči*—Android, Digitalna televizija, Set-top box (STB), Rest Protokol, UPnP Protokol**

I. UVOD

Za razumevanje ovog rešenja, potrebno je razumeti osnove digitalne televizije i android operativnog sistema. Takođe potrebno je razumeti način funkcionisanja postojeće DTV aplikacije za koju je ovo rešenje realizovano, kao i protokole korišćene za realizaciju ovog rešenja. Stoga je ovaj rad podeljen u 8 celina.

U prvoj celini dat je uvod. U drugoj celini je ukratko opisana digitalna televizija, android operativni sistem kao operativni sistem na kome se izvršava postojeća aplikacija, kao i par reči o json fajlovima. Treća celina ukratko opisuje način rada postojeće aplikacije da bi moglo da se razume šta je sve dodato u postojeću aplikaciju da bi se realizovalo ovo rešenje. Pošto je rešenje realizovano za STB uređaj, jedno od ključnih i osnovnih pitanja je pitanje vidljivosti i povezivanja STB uređaja i uređaja sa kojih se vrši akcija prebacivanja sadržaja na STB. Stoga je četvrta celina posvećena otkrivanju i povezivanju. U petoj celini će biti reči o REST arhitekturi na kojoj se bazira server, a koji predstavlja i način komunikacije mobilnog uređaja i STB-a kao i osvrt na sličan rad koji se bavio rest arhitekturom. Šesta celina je posvećena udaljenoj kontroli u kojoj je opisan sam server kao i resursi koje on podržava, dok se u sedmoj celini govori o načinu i rezultatima testiranja. U osmoj celini dat je kratak zaključak.

II. TEORIJSKE OSNOVE

A. Digitalna televizija

Predstavlja dominantan izvor zabave u domaćinstvima prema brojnim istraživanjima [1] sprovedenim u svetu sa udelom od skoro 80%. Razvojem tehnologije do tada dominantna analogna televizija svoje mesto je ustupila digitalnoj koja je donela značajne benefite u pogledu kvaliteta slike i zvuka, uštede električne energije, prijem slike i zvuka u pokretu, kao i bolju iskorišćenost frekvencijskog opsega. Razvojem interneta, sa stanovništva korisnika dolazi do revolucije u digitalnoj televiziji, jer televizija postaje vid dvosmerne komunikacije između digitalne televizije i njenih interaktivnih servisa sa jedne strane i korisnika sa druge. Samim tim korisnik dobija mogućnost da bira šta će da želi i kada. Takodje dolazi do novog načina distribuiranja signala, kroz već postojeću mrežnu infrastrukturu koji je definisan IPTV (eng. Internet protocol television) tehnologijom. Ovo je omogućilo još bržu ekspanzuju digitalne televizije jer se koristi već postojeća arhitektura. Postojeća aplikacija za pristup sadržaju koristi OTT (eng. Over the top) protokol koji omogućava pristup sadržaju preko internet konekcije, bez potrebe da se korisnik nalazi u mreži operatera. Takođe se koristi i DASH (eng. Dynamic Adaptive Streaming over HTTP) protokol, kao protokol koji određuju kvalitet video sadržaja u zavisnosti od brzine internet konekcije.

B. Android operativni sistem

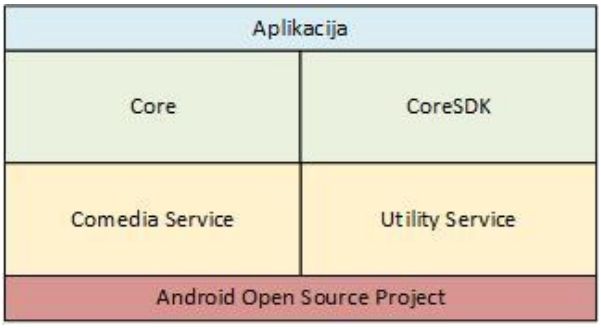
Android operativni sistem je operativni sistem razvijen od strane kompanije Gugl (eng. Google), prema kojoj je operativni sistem dostupan na preko dve milijarde uređaja [2]. Prevashodno namenjen za mobilne uređaje, trenutno je zastupljen u skoro svakom uređaju potrošačke elektornike, počevši od pametnih satova preko pametnih kuća, a u zadnje vreme se pojavljuje čak i u automobilima. Razlog za njegovu rasprostranjenost leži u činjenici da je to operativni sistem otvorenog koda (eng. Open source) dostupan pod Apache licencom. Takođe postoji velika zajednica ljudi koja održava i menja izvorni kod android-a. Programski kod android-a je dostupan preko Android Open Source Project-a, i postojeća aplikacija se upravo zasniva na AOSP projektu, zbog čega u njoj nisu implementirani servisi kompanije Gugl.

C. JSON fajl

JSON (eng. Javascript object notation) predstavlja otvoreni standard koji definiše razmenu poruka razumljivu ljudima [3].

Često se koristi za serijalizaciju i prenos struktuiranih podataka preko mrežne veze. Sastoji se od parova ključ:vrednost.

III. OPIS DTV APLIKACIJE



Slika 1. Arhitektura DTV aplikacije

Sa slike 1, može se videti, da se postojeća aplikacija sastoji iz 3 dela:

- Aplikativni deo
- Comedia servis i Utility servis, koje služe za reprodukciju MPEG_DASH sadržaja i promenu sistemska podešavanja ploče na kojoj se izvršava aplikacija.
- AOSP deo

Sam aplikativni deo je podeljen na tri dela. UI aplikacija, koja predstavlja glavni deo aplikacije koja je zadužena za iscrtavanje sadržaja po ekranu, u njoj je definisan ceo izgled aplikacije. Oslanja se na core i na coreSDK biblioteke definisane ispod nje.

Core biblioteka je biblioteka u kojoj se nalazi skup interfejsa (eng. Interfaces) i rukovaoca(eng. Handlers).

CoreSDK biblioteka je biblioteka u kojoj su realizovane implementacije interfejsa u core biblioteci, ali takođe ovde se nalazi i skup specifičnih interfejsa i njihovih implementacija koji nisu mogli biti realizovani u okviru core biblioteke.

Za potrebe ovog rešenja realizovane su sledeće klase koje implementiraju interfejs rukovaoca:

1. HttpServerHandler
2. SsdpServerHandler

Kao i klase koje predstavljaju serverske resurse.

3. CurrentMediaResponse
4. StbStatusResponse
5. remoteControllerReponse

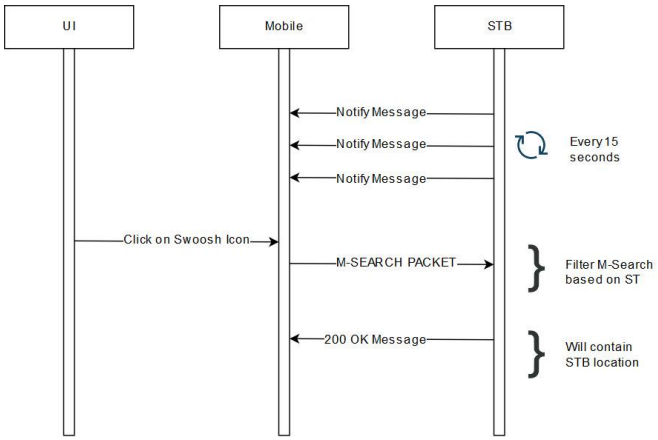
Više o ovim klasama, kao i njihovoj implementaciji biće rečeno u sledećim poglavljima.

IV. OTKRIVANJE I POVEZIVANJE UREDJAJA

Tokom reprodukcije digitalnog sadržaja, ukoliko se korisnik nalazi u istoj mreži kao i STB uređaj, na njegovom mobilnom uređaju se pojavljuje ikonica, koju ukoliko korisnik odabere dobija spisak svih STB uređaja koji se nalaze u njegovoj mreži. Klikom na STB uređaj iz liste, korisnik se povezuje na željeni STB. Povezivanje i otkrivanje je obavljeno putem UPnP protokola. UPnP protokol je skup mrežnih protokola koji omogućava automatsko pronalaženje, povezivanje i korišćenje uređaja koji su priključeni na računarsku mrežu [4]. Način povezivanja i otkrivanja je sledeći.

Nakon pokretanja STB uređaja, u fazi inicijalizacije se inicijalizuju SsdpServerHandler, koji predstavlja rukovaoc za otkrivanje i povezivanje, kao i HttpServerHandler, koji predstavlja rukovaoc za HTTP server koji se nalazi na STB uređaju. Nakon toga, STB uređaj na svakih 15 sekundi šalje NOTIFY pakete na adresu 239.255.255.250:1900, koja predstavlja multicast adresu.

U okviru svakog NOTIFY paketa nalaze se podaci vezani za STB uređaj, kao što su verzija HTTP protokola preko kojeg se šalju paketi, adresa i port na koju se šalju poruke, kao i ostali podaci definisani UPnP standardom. Sa druge strane mobilni uređaj će osluškivati NOTIFY pakete u pozadini, i ukoliko prepozna da NOTIFY paketi dolaze od strane STB uređaja, mobilni uređaj će da pošalje M-SEARCH paket na multicast adresu koju STB osluškuje. Kada se M-SEARCH paket pojavi na mreži, STB filtrira M-SEARCH paket na osnovu search-target (ST) polja u okviru M-SEARCH paketa, i ukoliko se polje podudara sa unapred definisanim stringom, STB uređaj odgovara sa 200 OK paketom u kome se nalazi adresa i resurs na koju mobilni telefon može da šalje komande. Dijagram otkrivanja i povezivanja dat je na slici 2.



Slika 2. Dijagram otkrivanja i povezivanja

V. REST ARHITEKTURA

Rest (eng. Representational State) predstavlja jednu od navažnijih i najpopularnijih arhitektura za kreiranje web aplikacija i web usluga [5]. Rest arhitektura je zvanično predstavljena u doktorskoj disertaciji Roja Fildinga 2000. godine[6]. Neki od principa Rest arhitekture su:

1. Zasnovan na resursima, gde svaki resurs ima svoj identifikator
2. Nema stanja
3. Klijent-Server arhitektura

Rest se oslanja na HTTP protokol i koristi metode HTTP protokola za pristup resursima. Neki od tih metoda su:

1. GET – Prikaz, odnosno čitanje određenog resursa.
2. POST – Kreiranje novog resursa
3. PUT – Ažuriranje ili zamena resursa.

Tokom izrade ovog rešenja korišćena je rest arhitektura kao način na koji će mobilna aplikacija da šalje zahteve na server STB uređaja, i način na koji će STB uređaj da odgovara aplikaciji.

Jedna od stvari koja se posebno ističe kod rest arhitekture, i samih restful servisa je da su veoma intuitivni kao i da se oslanjaju na već postojeću HTTP infrastrukturu. Takođe su veoma prilagodljvi jer način komunikacije ne mora da bude samo JSON fajl, a zbog mogućnosti keširanja povećava efikasnost čitavog sistema. O prednostima REST arhitekture postoji mnogo radova a naveo bih rad mojih kolega [8], koji su imali zadatak da objedine podatke iz DTV transportnog toka sa podacima sa interneta, te da te objedinjene podatke prikazuju klijentu. Oni su kao rešenje ponudili RESTful API koji se bazira na REST arhitekturi, i u svom radu su zaključili da je upravo REST arhitektura zbog svih njenih navedenih prednosti bila bolji izbor od npr. WSDL (eng. Web Service Description Language) kombinovanog sa SOAP (eng. Simple Object Access Protocol) protokolom.

VI. UDALJENA KONTROLA

Samo otkrivanje i povezivanje je opisano u poglavlju 4. Nakon toga, ukoliko korisnik izvrši swoosh akciju (koja predstavlja prevlačenje prstom na gore dok reprodukuje multimedijalni sadržaj), tada mobilni uređaj na IP adresu STB uređaja, a na resurs currentMediaResponse putem POST metode šalje JSON fajl koji u sebi sadrži sledeće podatke.

1. item_type – Predstavlja tip multimedijalnog sadržaja koji korisnik želi da reprodukuje. Može biti tv kanal, ili video na zahtev.
2. Playback_type – Predstavlja tip reprodukcije. U slučaju tv kanala, može da bude emisija emitovana u prošlosti (eng. catchUP), trenutna emisija ali pokrenuta ispočetka (eng. startOver), ili trenutna emisija (eng. Live). U slučaju videa na zahtev ovaj parametar se ignoriše.
3. programID – Predstavlja jedinstveni broj emisije za koju je zatražena reprodukcija.
4. fileID – Jedinstveni identifikator fajla kojeg želimo da pustimo na bekendu.
5. MediaMark – Broj koji predstavlja od koje sekunde treba da nastavimo reprodukciju. Samo za video na zahtev.
6. UserID – Jedinstveni identifikator korisnika na bekend strani.

Server koji se koristi u izradi ovog rešenja je definisan u HttpServerHandler klasi. Sama podrška za server se ispod haube oslanja na restlet biblioteku[9]. U HttpServerHandler klasi se samo definiše novi server kojeg implementira ova klasa, kao i dostupni resursi. Za svaki resurs koji server podržava definisana je odgovarajuća klasa.

Zadatak currentMediaResponse klase je da odreaguje na POST metodu koju će da prozove mobilni uređaj. Potrebno je isparsirati json fajl, proveriti validnost podataka u njemu, npr. Da li je trenutni id ulogovanog korisnika isti kao i userId koji je stigao u json fajlu, da li id fajla postoji na bekendu, itd. Zatim je potrebno proveriti da li se STB nalazi u stanju iz kojeg je moguće pustiti medija fajl. Ukoliko sve provere prođu uspešno, potrebno je pustiti traženi fajl i vratiti status kod 201, a u slučaju greške je potrebno vratiti status kod 401 i odvarajući json fajl sa porukom o grešci.

Još jedan od resursa koje imamo na serveru je stbStatusResponse. Naime, mobilni uređaj će svake sekunde slati zahtev za statusom STB uređaja, pa je njegov zadatak da odreaguje na ove zahteve. U status STB uređaja ulaze sledeći podaci:

1. userId
2. deviceId
3. playback – play/pause/none
4. assetId
5. subtitles – lang/none
6. audiolang – lang/none
7. epgstatus – epgEventId
8. mediaMark
9. parentalStatus
10. tvVolume

Poslednji resurs dostupan na serveru je remoteControllerReponse. On je zadužen za simulaciju daljinskog upravljača, tako što mobilni telefon preko rest protokola šalje json fajl sa željenim tasterom koji se simulirao na mobilnom telefonu. Zadatak ovog resursa je da odreaguje na POST zahtev, te da simulira pritisak određenog tastera na daljinskom upravljaču. Ovo je urađeno tako što se prvo isparsira parametar iz json fajla, i mapira na određenu vrednost iz KeyEvent klase. Nakon toga se koristi metoda *sendKeyDownUpSync* iz *Instrumentation* klase kojom se simulira odgovrajuće dugme na daljinskom upravljaču.

VII. NAČIN I REZULTATI TESTIRANJA

Testiranje je obuhvatalo dve faze. U prvoj fazi se obavljalo testiranje otkrivanja i povezivanje mobilnog uređaja i STB uređaja, dok je u drugoj fazi testirano izvršavanje komandi sa mobilnog uređaja, koje je obuhvatalo i puštanje multimedijalnog sadržaja i daljinsku kontrolu STB uređaja. tj simulaciju daljinskog upravljača. U prvoj fazi, rezultati pokazuju da se mobilni uređaj svaki put uspešno poveže na STB uređaj. Izvršeno je preko 20 merenja, i svaki put kada bi se mobilni uređaj povezao na istu mrežu kao STB pojavila bi se ikonica za swoosh opciju, i nakon klika na swoosh ikonicu, mobilni uređaj bih poslao M-SEARCH paket, koji bi STB prepoznao i odgovorio sa 200 OK porukom. Za posmatranje paketa kroz mrežu korišćen je wireshark program [6]. U drugoj fazi testirana je većina slučajeva kad STB može i kad STB ne može da pusti multimedijalni sadržaj. Nisu pokriveni svi slučajevi jer je varijacija stanja u kojima STB može da se nađe zaista prevelika. Za testirane slučajeve STB je svaki put vratio odgovarajući kod (201 ili 401). Da bismo bili sigurni da rešenje radi svaki put, testirali smo i sa pogrešno poslatim podacima, gde npr. korisnički id broj sa mobilne aplikacije nije odgovara identifikacionom broju korisnika koji je ulogovan na STB, kao i slanjem drugih netačnih podataka, ili čak praznih podataka. Ovim je potvrđeno da je STB u stanju da odreaguje na pogrešno poslate podatke, iako će mobilni uređaj svaki put slati prave podatke.

VIII. Zaključak

U ovom radu predstavljeno je unapređenje već postojeće DTV aplikacije podrškom za daljinsku kontrolu koja u velikoj meri poboljšava korisničku iskustvo i prelazak sa uređaja manjeg ekrana na uređaje većeg ekrana sa kojih je mnogo bolji doživljaj konzumacije digitalnog sadržaja.

Aplikacija sa uređaja manjeg ekrana i STB aplikacija se otkrivaju i povezuju putem UPnP protokola, dok se sama razmena podataka odvija preko json poruka koje klijent šalje na odgovarajući resurs na serveru, a server odgovara u skladu sa primljenim porukama i lokalnom obradom podataka.

Rezultati pokazuju da se aplikacija ponaša u skladu sa zahtevima specifikacije.

Mogućnosti za dalji rad na ovom proširenju su velike, jer je vrlo lako proširiti serversku stranu dodatnim resursima.

Zahvalnica

Ovaj rad je delimično finansiran od strane Ministarstva za prosvetu, nauku i tehnološki razvoj Republike Srbije, na projektu broj: TR32030.

Abstract

This paper presents one solution for the remote control of the STB platform through the REST protocol. The solution has been implemented for the already existing DTV application and represents its improvement. The solution allows the user to continue watching content from a mobile phone, tablets and similar devices on the STB device by swiping up while consuming multimedial content. Multimedial content is then paused on the phone, and continues to play on STB device. Also, the solution adds support for simulation of the remote control, so that user can control the STB via a mobile device.

One solution for remote control of STB platform via REST protocol

Unapređenje arhitekture sloja za apstrakciju fizičke arhitekture DTV srednjeg sloja

Lara Milovanović, Miroslav Bako, Milan Savić

***Apstrakt*—DTV srednji sloj je najvažniji deo programske podrške za TV prijemnike, koji sadrži gotovo kompletnu DTV funkcionalnost i omogućava izvršavanje aplikacija. Zavisnost DTV srednjeg sloja od fizičke arhitekture ciljane platforme oduvek je predstavljala barijeru u rayvoju DTV srednjeg sloja. U ovom radu opisan je problem prenošenja DTV srednjeg sloja, odnosno sloja za apstrakciju fizičke arhitekture, kao i unapređenje arhitekture ovog sloja. Datim unapređenjem omogućeno je da DTV srednji sloj podržava više HAL API-ja istovremeno, što u velikoj meri doprinosi portabilnosti DTV srednjeg sloja, i omogućava razvijanje hibridnog STB (Set-top box) uređaja, koji može da emituje OTT sadržaj, kao i sadržaj dobijen iz DVB transportnog toka.**

***Ključne reči*—STB; DTV; Android; DTV srednji sloj; OTT; HAL; SoC; Media Codec; Hibridni STB;**

I. Uvod

DTV srednji sloj je je najvažniji deo programske podrške za TV prijemnike, koji sadrži gotovo kompletnu DTV funkcionalnost i omogućava izvršavanje aplikacija.

Važna osobina DTV srednjeg sloja je da on apstrahuje funkcionalnosti DTV uređaja, fizičke arhitekture i operativnog sistema, i na taj način obezbeđuje da proizvođač aplikativne DTV programske podrške ne mora da bude upoznat sa specifičnostima fizičke arhitekture.

Različiti proizvođači hardverskih komponenata imaju različit mehanizam upravljanja (spregu) nad ovim komponentama. Iz tog razloga se javlja glavni problem pravljenja univerazalnog DTV srednjeg sloja koji može da funkcioniše na svim platformama.

Kako bi se omogućila DTV funkcionalnost na određenoj platformi, neophodno je preneti sloj za apstrakciju fizičke arhitekture (eng. Hardware Abstraction Layer - HAL) srednjeg sloja na ciljanu platformu.

Sloj za apstrakciju fizičke arhitekture predstavlja programski sloj u kome se vrši apstrakcija pristupa ka rukovaocima hardverskih komponenti (eng. drivers). Prilikom prenošenja DTV srednjeg sloja na određenu platformu, korišćenjem HAL-a se postize da DTV srednji sloj ne mora da se menja, već se sve promene koje su vezane za ciljanu platformu dodaju u HAL.

S obzirom na prethodno pomenute probleme, cilj ovog rada je opis problema prenošenja DTV srednjeg sloja, odnosno sloja za apstrakciju fizičke arhitekture, kao i unapređenje arhitekture ovog sloja. Datim unapređenjem omogućeno je da DTV srednji sloj podržava više HAL API-ja istovremeno, što u velikoj meri doprinosi portabilnosti DTV srednjeg sloja, i omogućava razvijanje hibridnog STB uređaja, koji može da emituje OTT sadržaj, kao i sadržaj iz DVB transportnog toka.

Milan Savić, Nacionalni institut za nauku i razvoj RT-RK, Narodnog fronta 23A, 21000 Novi Sad, Srbija (e-mail: Milan.Savic@rt-rk.com).

II. Teorijske osnove

A. Android TV

Android TV je proširenje osnovne Android platforme razvijeno od strane Google-a, posebno za televizijske i samostalne multimedijalne uređaje [1].

U okviru Android TV platforme, Google nudi skup GTVS (eng. Google TV Services) [2] aplikacija. GTVS aplikacije su skup aplikacija razvijenih od strane kompanije Google sa ciljem da se poboljša iskustvo korišćenja Android TV platforme. Neki od pripadnika GTVS aplikacija i servisa su unapred instalirane na sistemsku particiju Android TV-a, dok korisnik može da instalira i ostale koje se nalaze u Google-ovoj prodavnici aplikacija (eng. Google Play Services). Neke od aplikacija razvijanih od strane GTVS-a, koje su unapred instalirane (preintegrisane) na sistemsku particiju Android TV-a su:

- "Leanback Launcher" - pokretač aplikacija ya Android TV
- "Google Asssistant" - pomoć i pretraga
- "Play Store" - zvanična Google prodavnica Android aplikacija
- "Play Movies" - aplikacija za gledanje filmova i drugih TV emisija
- "You Tube" - aplikacija za promovisanje video sadržaja

Da bi proizvođači Android uređaja dobili dozvolu da preintegrišu GTVS aplikacije, Android TV platforma mora da prođe Google-ov sertifikacioni proces.

B. Android programska podrška za TV prijemnike

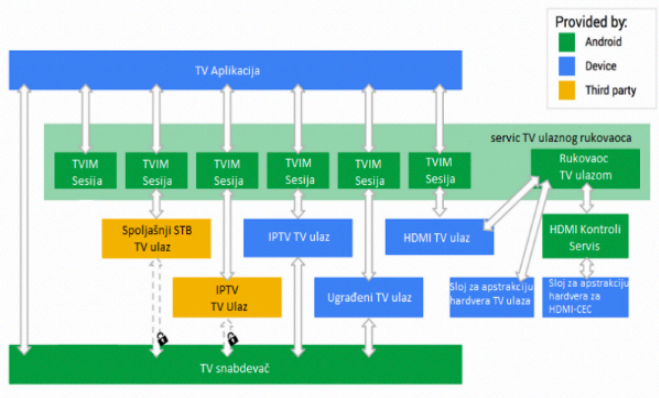
Android programska podrška za TV prijemnike (eng. TV Input Framework – TIF) [3] definiše aplikativnu programsku spregu i standardizuje način implementacije dopremanja emitovanog sadržaja do TV aplikacije. TIF omogućuje implementaciju TV ulaza preko kog je moguće reprodukovati sadržaj sa mrežnog poslužioca i/ili iz DVB transportnog toka

podataka, kao i pretragu televizije uživo. Programska podrška ne teži ka tome da implementira TV standarde ili regionalne zahteve, ali proizvođačima uređaja omogućava da lakše ispune regionalne digitalne TV standarde bez ponovne implementacije.

C. Komponente Android programske podrške za TV prijemnike

TIF se sastoji od:

- TV aplikacija (eng. TV Application) – aplikacija pomoću koje korisnik rukuje hibridnom programskom podrškom za TV prijemnike
- TV snabdevač (eng. TV Provider) – baza podataka sa kanalima, programima I pratećim dozvolama
- TV ulaz (eng. TV Input) – aplikacija koja predstavlja jedan izvor TV sadržaja
- Ulazna TV fizička arhitektura (eng. TV Input Hardware Abstraction Layer) – fizička definicija arhitekture koja omogućuje sistemskim TV ulazima pristup fizičkoj arhitekturi specifičnoj za TV prijemnike
- Roditeljska kontrola (eng. Parental Control) – tehnologija koja omogućava blokiranje kanala I programa
- HDMI-CEC – tehnologija koja omogućava daljinsku kontrolu raznih uređaja putem HDMI-CEC poruka



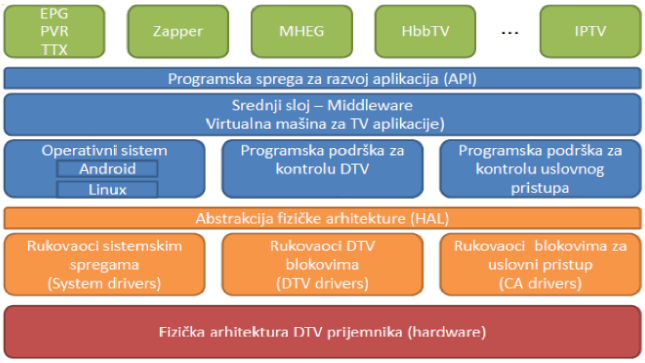
Sl. 1. TIF arhitektura

Na osnovu arhitekture sa slike se može zaključiti:

- Korisnik može da vidi i bude u direktnom kontaktu sa TV aplikacijom
- TV aplikacija prikazuje sadržaj sa TV ulaza
- TV aplikacija nije u mogućnosti da direktno komunicira sa TV ulazima, već je komunikacija ostvarena pomoću rukovaoca TV ulazom koji identifikuje stanje TV ulaza za TV aplikaciju

D. Programska podrška DTV prijemnika i koncept DTV srednjeg sloja

Arhitektura programske podrške za TV prijemnike je slojevita, gde svaki sloj ima posebnu naemenu. Primer uobičajenog rasporeda programskih slojeva TV prijemnika može se videti na Sl. 2.



Sl. 2. Programska podrška DTV prijemnika

Najvažniji deo programske podrške, koji sadrži kompletnu DTV funkcionallnost i omogućava izvršavanje aplikacija je DTV srednji sloj (eng. Middleware). Uloga srednjeg sloja je da realizuje najvažnije operacije kao što su raščlanjavanje DVB podataka, kontrola pristupa i organizacija servisa, prikupljanje podataka o programima (eng. Event Information Table – EIT), podrška za snimanje, kontrola podsetnika, reprodukcija (dekodovanje) multimediijalnih sadržaja, kao i da kontroliše fizičku arhitekturu kroz komunikaciju sa nižim slojevima i da obezbedi potrebne programske sprege ka višim programskim slojevima.

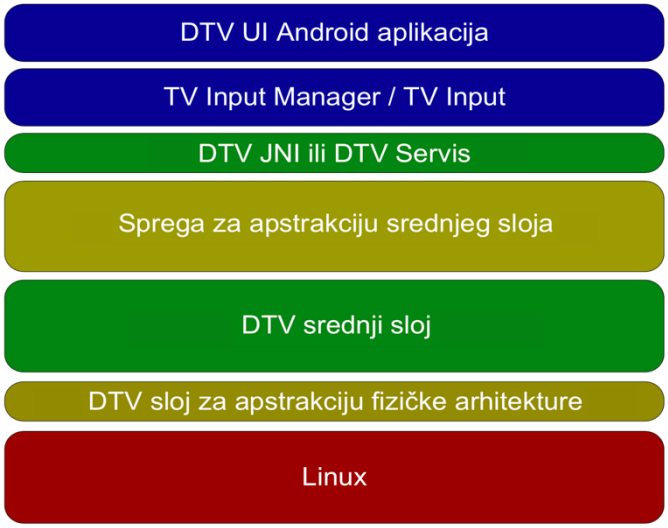
Važna osobina srednjeg sloja je da on apstrahuje funkcionalnosti DTV uređaja, fizičke arhitekture i operativnog sistema, i na taj način obezbeđuje da proizvođač aplikativne DTV programske podrške ne mora da bude upoznat sa specifičnostima fizičke arhitekture. Drugim rečima, srednjii sloj formira virtuelnu celinu na kojoj se izvršava aplikativni deo programske podrške. Ovo takođe garantuje identično izvršavanje iste aplikacije na različitim fizičkim arhitekturama ukoliko se koristi isti srednji sloj.

E. Arhitektura DTV srednjeg sloja

DTV srednji sloj sastoji se iz tri osnovne celine [4]:

- Jezgro srednjeg sloja – zaduženo za realizaciju osnovnih DTV funkcionalnosti i nezavisno je od fizičke platforme
- Sloj za apstrakciju srednjeg sloja (eng. Middleware Abstraction layer, MAL) – vrši enkapsulaciju svih funkcionalnosti srednjeg sloja kroz programsku spregu koja omogućava laku integraciju sa slojevima višeg nivoa
- Sloj za apstrakciju fizičke arhitekture (eng. Hardware Abstraction Layer, HAL) – sadrži funkcionalnost koja je direktno vezana za fizičku arhitekturu. Da bi se omogućila funkcionalnost DTV srednjeg sloja na određenoj platformi, potrebno je ovaj sloj preneti na ciljanu platformu.

F. *Veza Android aplikacije i DTV srednjeg sloja*



Sl. 3. Veza Android aplikacije i DTV srednjeg sloja

- Funkcionalnosti srednjeg sloja uobličene su u okviru DTV klase koja obezbeđuje standardizovan Java API za pisanje DTV aplikacija.
- U okviru implementacije TV Input klase, koriste se pozivi DTV klase koja daje na raspolaganje sve osnovne elemente DTV srednjeg sloja
- DTV JNI povezuje Java sloj sa nativnim kodom (korišćenjem standardnih Java Native Interface mehanizama).
- Implementacija DTV klase u Javi poziva odgovarajuće C funkcije.
- DTV JNI omogućava pozivanje svih MAL API funkcija.
- MAL API omogućava pristup svim funkcionalnostima srednjeg sloja.
- Srednji sloj realizuje DTV funkcionalnosti.
- Sprega za apstrakciju fizičke arhitekture realizuje konkretnu komunikaciju sa fizičkim rukovaocima DTV blokovima.

G. SoC API i *Media Codec*

SoC (eng. System on a chip) API predstavlja spregu za upravljanje rukovaocima fizičkih komponenti (drajverima) koji je svaki proizvođač fizičke arhitekture dužan da obezbedi kako bi DTV srednji sloj mogao biti prilagođen za izvršavanje na određenoj platformi. SoC API je uglavnom pisan u jezicima niskog nivoa i zahteva da aplikacije koje ga pozivaju takođe budu niskog nivoa.

Media Codec [5] predstavlja modul univerzalne Android programske sprege. Omogućava pristup za rukovanje komponentama fizičke arhitekture ali putem prethodno pomenute univerzalne Android programske sprege koja je dostupna na svim Android uređajima. Proizvođači hardverskih komponenti su dužni da omoguće da ova programska podrška radi na njihovim platformama. Komponente kojima se može upravljati kroz Media Codec su A/V dekoderi, enkoderi, i slično. Pored upravljanja ovim komponentama, Media Codec takođe nudi spregu sa hardverskim blokovima za dekripciju sadržaja tako da time podržava ne samo rad sa nezaštićenim, već i sa zaštićenim multimedijalnim sadržajem.

III. Opis problema

Da bi se omogućilo izvršavanje aplikacija i kompletna DTV funkcionalnost na određenoj platformi, potrebno je preneti sloj za apstrakciju fizičke arhitekture DTV srednjeg sloja na ciljanu platformu. Svaki proizvođač fizičke platforme dužan je da obezbedi API za rukovanje fizičkom arhitekturom. Sa druge strane, da bi se omogućilo rukovanje fizičkom arhitekturom, HAL sloj DTV srednjeg sloja dužan je da implementira API dobijen od strane proizvođača, bez potrebe za poznavanjem detalja realizacije te arhitekture.

Postoje različite promene DTV srednjeg sloja shodno metodi dopremanja TV sadržaja. Na primer, moguće je da na jednom STB uređaju DTV srednji sloj služi za reprodukciju DVB sadržaja, dok na drugom STB uređaju služi za reprodukciju sadržaja dobijenog preko mreže. STB uređaji sa pristupom internetu omogućili su korišćenje OTT sadržaja poput:

- TV-sadržaja koji se doprema posredstvom interneta (stream ili download) - Internet TV
- Socijalnih internet servisa
- Web servisa opšte namene

Omogućavanjem pristupa internetu bilo je potrebno obezbediti adekvatnu zaštitu datog sadržaja radi dalje distribucije. Kako bi se takav sadržaj mogao reprodukovati, potrebno ga je dekriptovati.

Upravljanje digitalnim pravima (eng. Digital Rights Managment – DRM) [6] je sistematski pristup zaštiti autorskih prava za digitalne medije. Svrha DRM-a je da spreči neovlaštenu redistribuciju digitalnih medija i ograniči načine na koje korisnici mogu kopirati sadržaj koji su kupili.

Drajveri nemaju direktnu podršku za dešifrovanje zaštićenog sadržaja,zbog čega bi se za svaku arhitekturu platforme morao praviti poseban mehanizam za dešifrovanje. Međutim, Android je pružio univerzalno rešenje za dešifrovanje zaštićenog sadržaja u vidu *Media Codec* API-ja koji je nezavisan od fizičke arhitekture platforme.

IV. Koncept rešenja

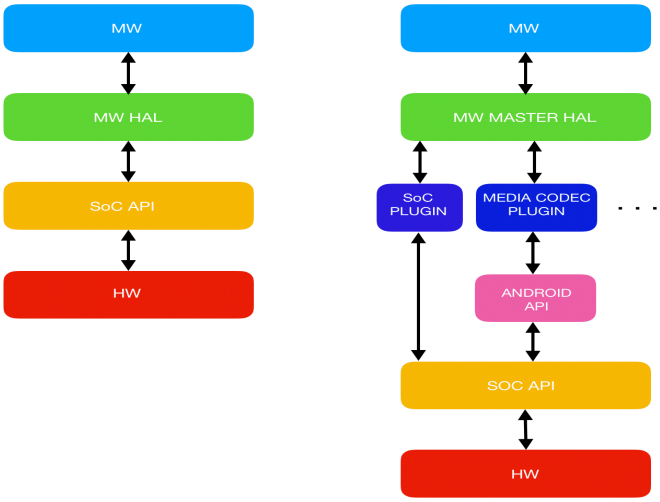
Sa pojavom Android-ovog *Media Codec* mehanizma, proces razvijanja OTT uređaja znatno je ubrzan, jer je za apstrakciju HAL sloja korišćen Android-ov API.

Media Codec API je univerzalan za sve fizičke platforme, što znači da DTV srednji sloj koji koristi *Media Codec* mehanizam za dopremanje TV sadržaja predstavlja univerzalno rešenje OTT middleware-a, nezavisno od fizičke arhitekture.

Sledeći izazov u unapređenju DTV aplikacija podrazumeva razvoj hibridnog STB uređaja koji koristi Android-ov *Media Codec* API za OTT sadržaj, dok za dobavljanje i reprodukciju sadržaja iz DVB transportnog toka koristi SoC API za datu platformu.

Ovo je postignuto podelom arhitekture DTV sloja za apstrakciju fizičke arhitekture na dva sloja, jedan ispod DTV srednjeg sloja koji služi kao glavni HAL modul, i ostali HAL moduli u vidu umetka (eng. plugin) koje kontroliše glavni

HAL. Korišćenjem ovakve arhitekture, za svaki SoC API se može nezavisno napraviti i testirati HAL plugin.



Sl. 4. Ilustracija stare i nove arhitekture DTV sloja za apstrakciju harvera

Plugini su realizovane kao deljene programske biblioteke. Glavni HAL modul pretražuje sve dostupne plugine u sistemu i dinamički ih učitava u radnu memoriju u toku izvršavanja DTV srednjeg sloja. Nakon učitavanja plugina u radnu memoriju mapiraju se pozivi ka funkcijama na određene memorijske adrese u okviru učitanih biblioteka. Tokom rada, DTV srednji sloj identifikuje koji sadržaj se reprodukuje i na osnovu toga se pozivaju zahtevane funkcije iz HAL-a koji se trenutno koristi za reprodukciju sadržaja. Ovakav mehanizam, pored osnovnog zadatka DTV srednjeg sloja koji je reprodukcija sadržaja, podržava i ostale napredne funkcionalnosti kao što su PVR, EPG. Pored toga, DTV srednji sloj nije ograničen da u jednom trenutku radi samo sa jednim HAL-om, nego je moguće da radi istovremeno sa svim učitanim HAL pluginima i jedino ograničenje predstavlja sama dostupnost fizičkih resursa ciljanog uređaja.

Ovakva arhitektura koja omogućava postojanje više HAL plugina istovremeno, pružila je rešenje za razvoj hibridnog STB uređaja koji koristi *Media Codec* plugin za OTT sadržaje, dok za DVB sadržaj razvija *SoC* plugin u zavisnosti od fizičke arhitekture ciljane platforme.

V. Zaključak

Zavisnost DTV srednjeg sloja od fizičke arhitekture ciljane platforme oduvek je predstavljala barijeru u razvoju DTV srednjeg sloja. Nova arhitektura DTV sloja za apstrakciju fizičke arhitekture koja je omogućila je korišćenje plugin-a, u velikoj meri doprinela je portabilnosti DTV srednjeg sloja, jer prenošenje na drugu platformu zahteva samo razvijanje SoC plugin-a za datu arhitekturu, bez potrebe za drugim izmenama u DTV srednjem sloju. Takođe, STB koji koristi *Media Codec* plugin, se vrlo brzo može transformisati u hibridni STB dodavanjem HAL plugin-a za SoC API.

VI. Zahvalnica

Abstract

The DTV middleware is the most important part of the software for TVs, which contains almost complete DTV functionality and allows execution of applications. The dependence of the DTV middle layer on the physical architecture of the target platform has always been a barrier in the DTV medium layer.

The aim of this paper is to describe the problem of porting the DTV middleware, precisely hardware abstraction layer, as well as the improvement of the architecture of this layer. By enhancing this feature, DTV middleware supports multiple HAL APIs at the same time, which greatly contributes to the portability of the DTV middle layer, and allows the development of a hybrid STB (Set-top box) device that can transmit OTT content as well as the content obtained from the DVB transport stream.

Improvement of the architecture of hardware abstraction layer in DTV middleware

Primena tehnologije Google Assistant u interaktivnoj digitalnoj televiziji

Aleksandar S. Lazić, Milan Z. Bjelica, *Member, IEEE*, Veljko Lj. Ilkić i Dejan Đ. Nađ

***Apstrakt*— U današnje vreme, sve više i više korisnika koristi usluge virtuelnih asistenata na različitim platformama (Android, Windows, iOS) i oni postaju sve zastupljeniji u svakodnevnim životnim aktivnostima, bilo da je to asistencija u kupovini namirnica, u vožnji do posla ili pak, u svrhu zabave korisnika. U okviru ovog rada istražena je i realizovana mogućnost primene tehnologije Google asistent u interaktivnoj digitalnoj televiziji na prijemniku zasnovanom na operativnom sistemu Android. Jedan od ciljeva je unapređenje korisničkog iskustva u vidu komplementiranja osnovnih funkcionalnosti poput izmene kanala ili nivoa jačine zvuka glasovnim komandama, i dodatnim mogućnostima izbora tačnog kanala, događaja ili video sadržaja na zahtev sa mogućnošću trenutnog ili naknadnog gledanja, zakazivanja snimanja i dr. Velika većina alata za prepoznavanje glasovnih komandi generiše rezultate naredbe u vidu slobodnog teksta ili struktuiranog objekta. Kako bi se taj rezultat iskoristio u postojećim TV aplikacijama, neophodno je detektovati šablone koji odgovaraju gore pomenutim naredbama.**

***Ključne reči*—Android, Google Assistant, Digitalna televizija, glasovna komanda, integracija, korisničko iskustvo, Actions on Google, Dialogflow, Set-top box (STB).**

I. Uvod

Digitalna televizija i video sadržaj su danas među najzastupljenijim vidovima medijske komunikacije sa korisnicima [1]. Sama televizija jeste komunikacioni medijum za slanje i prihvatanje pokretnih slika i zvuka. U poslednje dve decenije doživljava veliku ekspanziju u svetu, pre svega slanjem analognog TV prijemnika u istoriju, a zatim i razvojem softverske podrške i realizacijom prvog TV uređaja sa Android operativnim sistemom [2] u junu 2014. godine. Prema trenutnim istraživanjima, televizija uz Internet predstavljam dominantan izvor zabave u svetskoj populaciji [3], pre svega kada je reč o korisnicima srednjeg i starijeg životnog doba. Ovome doprinose i novi operativni sistemi na korisničkim uređajima, kao što je Android.

Android je najrasprostranjeniji operativni sistem u svetu za namenske uređaje poput pametnih telefona, tableta, satova, televizora i drugih kućnih uređaja. Glavna Androidova karakteristika je da je to sistem „otvorenog koda“ [4], tj. postoji zajednica programera gde svako može da ga izmeni, unapredi prema svojim potrebama i podeli sa drugim inženjerima. Arhitektura Androida može se podeliti u 5 celina, od najniže ka najvišoj:

- Sloj jezgra (Kernel);
- Sistemske (nativne) biblioteke;
- Izvršno radno okruženje;
- Okruženje za razvoj aplikacija;
- Aplikativni sloj;

Za realizaciju u ovom radu, poslednja dva sloja su bitna jer je to ono što korisnik vidi dok upravlja TV prijemnikom. Između ta dva sloja, odnosno između srednjeg sloja (*Middleware*) i aplikativnog sloja, nalazi se, specijalno dizajnirano za Android u televiziji, radno okruženje poznatije kao TV Input Framework (TIF) [5]. TIF omogućava manipulisanje bazom podataka u kojoj su smešteni TV servisi, standardizuje dopremanje sadržaja do TV aplikacije [6], omogućava pretragu kanala uživo, njihovo reprodukovanje iz DVB transportnih tokova itd. Programska podrška ne teži ka tome da implementira nove TV standarde, ali proizvođačima omogućava da lakše ispune regionalne digitalne TV standarde, bez ponovne implementacije.

Na današnjim aplikativnim platformama važnu ulogu zauzimaju virtuelni asistenti. Za svaku od platformi je karakterističan neki virtuelni asistent. Na primer, ukoliko korisnik koristi *Apple*-ove uređaje, asistent će mu biti *Siri*, Windows korisnicima je na raspolaganju *Cortana*, dok je za Android (a može se koristiti i na drugim platformama) namenjen Google asistent [7]. On poseduje veštačku inteligenciju i omogućava dvosmernu komunikaciju sa korisnikom u vidu govorne komunikacije ili pisanim putem. Izuzetno je dobro obučen, ima pristup Internetu, te konverzacija sa njim ostavlja utisak razgovora sa stvarnim čovekom. Osim zanimljivih konverzacija, Google asistent omogućava još pregršt korisnih funkcionalnosti posebno kada je reč o pametnim kućama (*Internet of things* [8]) gde je korisniku omogućeno da upravlja osvetljenjem, temperaturom i drugim parametrima u svom domu, koristeći glasovne komande. Po ugledu na to, slične akcije su omogućene i u integraciji asistenta u TV aplikaciji. Google asistent poseduje posebne platforme koje omogućavaju korisniku da osmisli bilo kakvu akciju, uz minimalno obučavanje asistenta i obradu podataka da bi se akcija izvršila.

Ključne reči za pozivanje asistenta su „*Hey Google“* ili *„Ok Google“*, dok, ukoliko korisnik želi da koristi mogućnosti implementirane u ovom radu, potrebno je da započne konverzaciju sledećom frazom – *„Talk to Stage application“*. Ova fraza je podložna promenama u zavisnosti

Aleksandar Lazić – Institut RT-RK, Narodnog fronta 23a, 21000 Novi Sad, Srbija (e-mail: aleksandar.lazic@rt-rk.com).

Milan Z. Bjelica – Institut RT-RK, Narodnog fronta 23a, 21000 Novi Sad, Srbija (e-mail: milan.bjelica@rt-rk.com).

Veljko Ilkić – Institut RT-RK, Narodnog fronta 23a, 21000 Novi Sad, Srbija (e-mail: veljko.ilkic@rt-rk.com).

Dejan Nađ – Institut RT-RK, Narodnog fronta 23a, 21000 Novi Sad, Srbija (e-maill:dejan.nadj@rt-rk.com).

od korisničkih podešavanja ili imena same TV aplikacije.

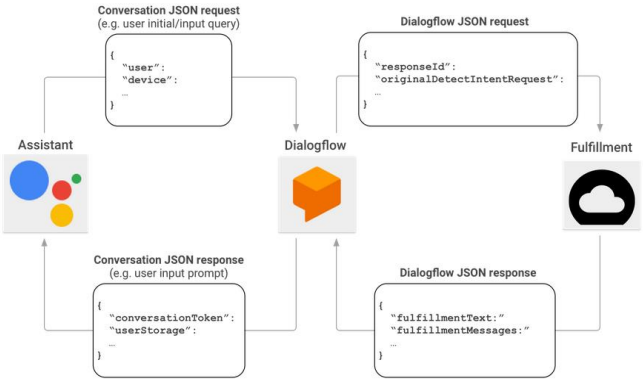
U okviru rada realizovane su komande za prikazivanje liste dostupnih kanala i filmova, komande za podatke o trenutnom kanalu, događaju na trenutnom kanalu, narednom događaju, prikaz događaja na određenom kanalu u određeno vreme kao i mogućnosti zakazivanja snimanja i podsetnika za gledanje događaja.

II. Prethodni rad i istraživanja

Upotreba Google asistenta i njegova integracija u aplikacije spada u rešenja prisutna prethodnih nekoliko godina. Kako je njegova popularnost uhvatila zamah, tako su inženjeri, ali i obični entuzijasti počeli da isprobavaju mogućnosti Google asistenta, uglavnom u svrhu zabave. Takođe, Google asistent je mnogo bolje integrisan i funkcionalniji u uređajima poput pametnih telefona, gde nudi mnoštvo raznolikih razgovora o brojnim temama iz svih sfera života i drugih mogućnosti, nego u pametnim televizorima ili STB uređajima, gde je konverzacija ograničena mogućnostima TV uređaja, te je i podrška zajednice za asistenta u TV aplikacijama utoliko „siromašnija" nego za telefone ili tablete.

Kako se Google asistent razvijao, tako su se razvijale i platforme koje omogućavaju svakom čoveku da napravi neku vrstu konverzacije sa Google Assistant-om. Postoje nekoliko platformi koje se koriste za to, u zavisnosti od potreba, složenosti naredbi, na raspolaganju su: *Actions on Google* i *Dialogflow* [9].

U prošlosti je na sličnu temu pisan naučni rad [10], gde je akcenat bio na izvršavanju zadate akcije, dok deo vezan za interakciju sa korisnikom nije bio od vitalne važnosti. Google asistent je obezbeđivao deo odgovora koji je statički, dok se drugi deo menjao u zavisnosti od zadate korisničke komande. U ovom radu se napravio iskorak, te akcenat nije više samo na izvršavanju akcije, već i na interaktivnom dijalogu između korisnika i asistenta. Osim osnovnih korisničkih naredbi za promenu kanala ili jačine zvuka, korisnik ima mogućnost da asistentu postavi pitanje, zatraži podatke o događajima, odnosno da se uspostavi interakcija između istih. Drugim rečima, asistent nije više prividno obučen za konverzaciju, već dobija veštačku inteligenciju i u pozadini rukuje željenim podacima, vraća korisniku smisleni odgovor ili opcije koje može da izabere, ali i izvršava željenu akciju i rezultat se može videti u samoj aplikaciji, prikazivanjem odgovarajućeg sadržaja. Iz tog razloga, za ovaj rad se nije koristila samo platforma *Actions on Google,* već i *Dialogflow* simultano, a grafički prikaz toga može se videti na Slici 1.



Slika 1 – Tok podataka od Google Assistant-a preko DialogFlow do Actions on Google platforme

III. Opis rešenja

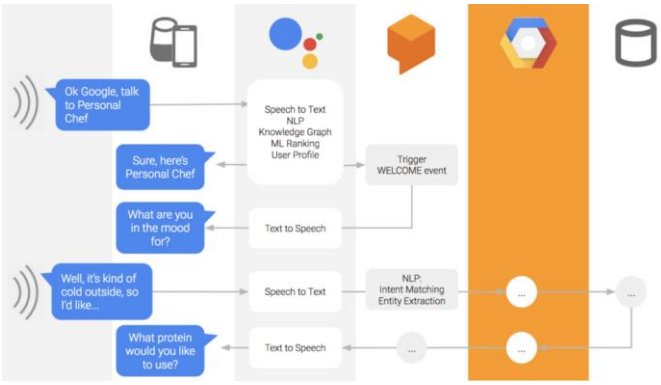
U ovoj sekciji dat je opis jednog rešenja obuke i integracije Google asistenta za složenije korisničke zahteve. Kao i u prethodno pomenutom naučnom radu [10], gde je bilo potrebno obučiti asistenta za jednostavnije komande, potrebno ga je obučiti i za složenije. Uporedni prikaz podržanih komandi u ovom radu u odnosu na prethodno pomenuti je tabelarno prikazan u Tabeli 1.

Table 1 - Uporedni prikaz podržanih komandi u naučnim radovima

Komande podržane u prethodnom radu	Komande podržane u ovom radu
Promena kanala unapred	Prikaz informacija o trenutnom kanalu
Promena kanala unazad	Prikaz informacija o trenutnom događaju na trenutnom/nekom drugom kanalu
Pojačavanje tona	Prikaz informacija o sledećem događaju na trenutnom/nekom drugom kanalu
Stišavanje tona	Prikaz informacija o događaju na određenom kanalu u određeno vreme
Potpuno utišavanje tona	Prikaz svih dostupnih kanala
Vraćanje na jačinu tona pre potpunog utišavanja	Prikaz dostupnih filmova (VOD)
Prebacivanje na kanal sa određenim brojem	Dodavanje/ brisanje podsetnika za neki događaj
	Dodavanje/brisanje događaja u listu za snimanje

Pored obuke, potrebno je generisati i odgovor korisniku i obaviti željenu akciju, ukoliko je to moguće, što je predstavljalo i najveći izazov u ovom radu. Korisnik više ne dobija odgovor u vidu obaveštenja da je željena radnja uspešno obavaljena, već uz dobavljeni TV sadržaj nastavlja

interakciju sa korisnikom nudeći mu dodatne opcije i nastavak dijaloga. Ceo princip rada dodatno je pojašnjen slikom 2.



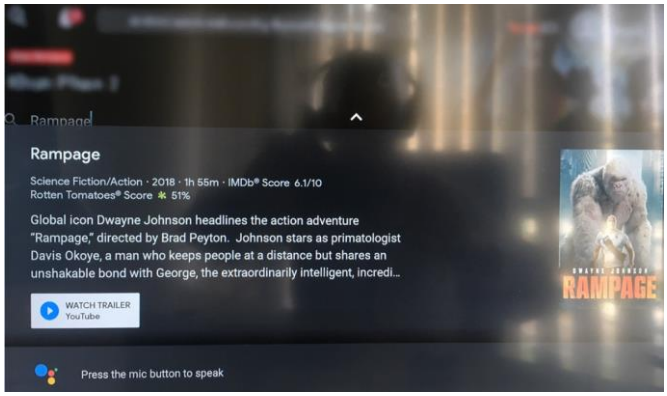
Slika 2 - Primer korisničkog zahteva

Na slici 2 dat je primer pod sistema od korisničkog zahteva, koji se unosi kao glasovna komanda i pokreće samog asistenta. Nakon toga asistent pokreće Dialogflow u potrazi za početnom akcijom (*Welcome intent)*. U nastavku korisnik zadaje komandu, a asistent pomoću Dialogflow i Actions on Google platforme šalje zahtev u aplikaciju. Aplikacija dobavlja neophodne podatke i istim putem ih vraća do korisnika, uz izvršavanje željene komande u pozadini.

Da bi obuka bila što efikasnija, poželjno je za svaku akciju (*Intent*) uneti pozamašan broj reči ili fraza koje korespondiraju željenoj akciji. Intuitivno, može se naslutiti da je ovo najlakša faza u ovom radu, ali je istovremeno iziskivala i određeno vreme da se u bazu mogućih korisničkih pitanja ili zahteva doda veliki broj TV servisa, TV događaja, filmova, serija i drugih sadržaja.

Druga, najizazovnija faza rada, je generisanje odgovora za korisnika, odnosno nastavak smislene konverzacije. Osnovni problem je bio što odgovor ne sme biti jednoznačan, već asistent mora posedovati veštačku inteligenciju. To se prevazilazi generisanjem različitih statičkih odgovora u zavisnosti od mogućih situacija (što nije bio slučaj u ovom radu) ili generisanje dinamičkih odgovora, koji u sebi treba da sadrže podatke o željenim TV servisima. Ono što jeste bila prepreka je činjenica da se podaci nalaze u aplikaciji, a da posluživač mora nekako dobaviti te podatke i prikazati ih u svom odgovoru korisniku. Za tu svrhu je korišćena baza podataka u kojoj su bili smešteni sadržaji iz aplikacije, kojima je posluživač pristupao i koristio ih. Korišćenjem baze podataka je rešen problem razmene podataka o TV servisima, između asistenta i TV aplikacije, tokom konverzacije sa korisnikom, jer je posluživač imao odakle da obezbedi podatke korisniku.

Kada je reč o akcijama prikazivanja TV servisa u samoj aplikaciji, uporedo su korišćeni Dialogflow, obezbeđen od strane Google-a i Android-ovi *intent*-i, tačnije namera za pretragu, što se može uočiti na slici 3.



Slika 3 - Primer pretrage filma iz aplikacije

Ukoliko asistent prepozna korisničku naredbu, započinje pretragu po bazi podataka. Nakon što je željeni TV servis pronađen, u zavisnosti od toga da li se traži neka specifična ili uopštena informacija, podaci se prikazuju ili se pušta određeni sadržaj.

Jedno od ograničenja ove implementacije je to što pokretanjem Google asistenta, odnosno njegovog agenta za akcije vezane za TV aplikaciju, moguće je komunicirati sa njim samo onoliko koliko je obučen. Drugi rečima, asistent nema pristup Internetu i ne mogu se dobiti druge informacije koje nisu vezane za aplikaciju. Konverzacija sa agentom se prekida jednostavnom komandom „Bye“, i tek tada se Google Assistant vraća u svoju osnovnu formu i može da pretražuje sve ostale podatke i informacije posredstvom Interneta.

IV. TESTIRANJE I VERIFIKACIJA

Zahvaljujući činjenici da je TV aplikacija sama po sebi robusna, kao i da je trebalo pokriti mnoštvo testnih slučajeva, izvršen je niz uporednih testova. Tri nezavisna korisnika su zadavali glasovne komande na osnovu kojih su vršena merenja.

. U cilju potvrđivanja funkcionalnosti realizovanog rešenja izvršeno je nekoliko različitih ispitivanja:

- Ispitivanje prepoznavanja unetih komandi;
- Ispitivanje uspešnosti izvršenja naredbi;
- Ispitivanje procenta uspešnosti prepoznavanja komandi od strane Google asistenta;
- Ispitivanje vremena odziva Google asistenta

Testovi su vršeni u normalnim uslovima, pri određenim šumovima, na engleskom jeziku. Svi slučajevi korišćenja sa rezultatima testiranja su prikazani u Tabeli 2.

Tabela 2 - Ispitivanje uspešnosti prepoznavanja i izvršavanja komandi

Ispitni slučaj	Rezultat
Prikaz informacija o trenutnom kanalu	USPEŠNO ZAVRŠEN
Prikaz informacija o trenutnom/sledećem događaju na trenutnom kanalu	USPEŠNO ZAVRŠEN
Prikaz informacija o trenutnom/sledećem događaju na nekom drugom kanalu	USPEŠNO ZAVRŠEN
Prikaz informacija o događaju na određenom kanalu u određeno vreme	USPEŠNO ZAVRŠEN
Prikazivanje liste dostupnih TV kanala	USPEŠNO ZAVRŠEN
Ispitivanje liste dostupnih filmova (VOD)	USPEŠNO ZAVRŠEN
Zakazivanje snimanja određenog TV sadržaja	USPEŠNO ZAVRŠEN
Brisanje događaja iz liste za snimanje	USPEŠNO ZAVRŠEN
Zakazivanje podsetnika za određeni TV sadržaj	USPEŠNO ZAVRŠEN
Brisanje događaja iz liste podsetnika za određeni TV sadržaj	USPEŠNO ZAVRŠEN

Iz Tabele 2 može se videti da su svi testni slučajevi pokriveni te da su uspešno izvršeni. Za svaki od ovih 10 testnih slučajeva je izvršeno u proseku 25 komandi. Proces ispitivanja prepoznavanja unetih glasovnih (pisanih) komandi je umnogome olakšan i Google-ovim simulatorom gde se jednostavnom može ispitati reakcija asistenta na korisničke pobude.

Kada je reč o procentu uspešnosti prepoznavanja korisničkih komandi od strane asistenta, uspešnost prepoznavanja je visokih 92%. Najbitniji faktor je izgovor engleskog jezika (srpski još nije podržan). Zahvaljujući visokom stepenu obučenosti asistenta i dobrom izgovoru komandi, uspešnost prepoznavanja komandi je na zavidnom nivou.

Ispitivanje vremena odziva u aplikaciji od trenutka izdavanja komande do trenutka odgovora ili izvršavanja iste. Za 10 ispitnih slučajeva je vršeno po 10 merenja za različite pod slučajeve. U zavisnosti od toga da li asistent treba da obezbedi samo podatke od TV sadržaju ili treba da odradi i akciju, vreme izvršavanja varira od 2 do 5 sekundi. Iz ugla korisničkog iskustva, može se diskutovati da li je vreme odziva zadovoljavajuće ili nije. U Tabeli 3 dat je uporedni prikaz vremena odziva za gore pomenuta 4 testna slučaja.

Tabela 3 - Ispitivanje vremena odziva na korisničku pobudu

Ispitni slučaj	Vreme odziva
Prikaz informacija o kanalu	~1,388
Prikaz informacija o trenutnom/narednom događaju	~1,913
Prikaz informacija o događaju u određeno vreme na određenom kanalu	~1,888
Prikaz svih kanala	~3,036
Prikaz svih filmova	~4,173
Brisanje događaja iz liste podsetnika	~2,098
Brisanje događaja iz liste za snimanje	~2,100
Zakazivanje snimanja određenog TV sadržaja	~2,734
Zakazivanje podsetnika za određeni TV sadržaj	~2,525

Vreme odziva je u proseku od 2 do 4 sekunde u zavisnosti od komande, zahvaljujući optimizovanoj pretrazi pojmova i ključnih reči. Najviše vremena iziskuje prikaz TV kanala, odnosno filmova, iz razloga što je potrebno prikazati mnogostruko više rezultata korisniku nego kada se zahtevaju informacije o samo jednom događaju.

V. Zaključak

U ovom radu predstavljeno je unapređenje postojećeg rešenja [10] integracije Google asistenta u TV aplikaciju na operativnom sistemu Android. Pored osnovnih komandi za upravljanje kanalima i jačinom tona, poboljšano je rešenje sa aspekta korisničkog iskustva, te je sada moguće imati prirodniju komunikaciju sa asistentom kao i njegovo izvršavanje složenijih komandi. Potrebno je napomenuti da je implementacija i integracija asistenta u aplikaciju potpuno autonomna, te je moguće ovo rešenje iskoristiti i u drugim aplikacijama za gledanje televizije uz minimalne izmene i prilagođavanja.

Rezultati dobijeni prilikom ispitivanja su zadovoljavajući, s tim da je cilj u narednom periodu da se dodatno poboljšaju koliko god da je to moguće.

Asistent je dodatno obučen za interaktivnu komunikaciju, iako nisu pokriveni svi slučajevi korišćenja u aplikaciji, jer ih ima mnogo. U tom svetlu, budući rad bi mogao da se bazira da dodatnom proširenju funkcionalnosti aplikacije prilikom korišćenja asistenta i omogućavanje navigacije kroz istu posredstvom isključivo glasovnih naredbi.

ZAHVALNICA

Ovaj rad je delimično finansiran od strane Ministarstva za prosvetu, nauku i tehnološki razvoj Republike Srbije, na projektu broj: TR32041.

ABSTRACT

Nowadays, more and more people are using virtual assistant services on various platforms (Android, Windows, iOS). They are becoming present in everyday life such as buying food in market, driving to the job, or for the purpose of an entertainment. This paper presents a software architecture that supports Google Assistant integration in TV application, designed for Android operating system. The aim is to enhance user experience, so previously added intents such as “channel up/down”, “volume up/down” are extended with some more complex commands such as finding TV channel by name and zapping to it or choosing some VOD and schedule it for recording or watching later, by using only a voice command. The majority of existing speech recognition tools provide the result of the speech processing in a free form textual output or structured form textual output. In order to use obtained outputs in an existing TV applications, it is necessary to detect patterns that correspond to mentioned commands.

Use of Google Assistant technology in the interactive digital television

Proširenje TV Input radnog okvira funkcionalnostima paketa Google Assistant u Android okruženju

Radenko Banović, Milan Z. Bjelica, Darko Dejanović, Milan Gvero

***Apstrakt* — U ovom radu je predstavljeno jedno rješenje proširenja TV input radnog okvira funkcionalnostima paketa Google Assistant. TV Input predstavlja programsku reprezentaciju jednog izvora odakle se prima TV sadržaj, te popunjava sadržaj u bazu podataka TV poslužioca. Proširenje TV Input radnog okvira se odnosi na prilagođavanje pretrage i prikaza EPG (electronic program guide) podataka smještenih u bazi podataka TV poslužioca tako da se oni nađu u Google Assistant rezultatima pretrage.**

***Ključne riječi*— Android, Digital TV, Google Assistant, DTV**

I. Uvod

U poslednje vrijeme raste popularnost upravljanja uređajima govorom [1], što je posebno interesantno u oblasti digitalne televizije, jer digitalna televizija nudi sve više sadržaja. Unos podataka daljinskim upravljačem otežava korištenje svih servisa koje nudi digitalna televizija.

Android TV je proširenje operativnog sistema Android dodatnim funkcionalnostima za TV uređaje (set-top box i smart TV). Android TV zadržava mogućnosti kao što su instaliranje aplikacija sa Google Play Store (npr. video igre), ili korištenje ostalih Google servisa kao što je Google Asistent [2].

Google Asistent je virtuelni lični pomoćnik razvijen od strane Google-a koji je dostupan i na Android TV uređajima od 2017. godine [3], a omogućuje dvostranu komunikaciju. Korisnici primarno komuniciraju sa Google Asistentom prirodnim glasom, ali je i unos preko tastature takođe podržan. Pretražuje internet i aplikacije koje su lokalno instalirane u slučaju da su aplikacije prilagođene i dozvoljavaju globalno pretraživanje njihovog sadržaja. Takođe, moguće je podešavati fizičke komponente uređaja, dodavati događaje u kalendaru itd.

Zadatak ovog rada je da omogući Google Asistentu pretraživanje baze podataka TV poslužioca proširenjem TV Input radnog okvira. Ukoliko se pronađe traženi sadržaj (npr. EPG (electronic program guide) sadržaj – naziv emisije) potrebno je iz rezultata pretrage omogućiti reprodukovanje živog TV sadržaja kanala za koji je pronađeni program vezan.

Ranije je pretragu TV baze podataka bilo moguće pozvati i rezultate pretrage prikazati samo u aplikaciji koja i skladišti podatke. Omogućujući Google Asistentu pretragu baze podataka TV poslužioca korisniku je omogućena lakša pretraga TV sadržaja, i lakši pristup željenom sadržaju.

Ovaj Rad je sačinjen od 5 poglavlja.

U drugom poglavlju se nalaze teorijske osnove neophodne za razumijevanje digitalne televizije, Android platforme, dostavljača sadržaja i Google Asistenta.

Treće poglavlje sadrži osnovne informacije o dvema aplikacijama koje je potrebno proširiti pri izradi ovog rada, opis ciljne platforme, kao i informacije o programskom okruženju i implementaciji rješenja u obje aplikacije.

Četvrto poglavlje sadrži opis testova koji su obavljeni nakon izrade rješenja radi validacije istog, i diskutovani su dobijeni rezultati.

Peto poglavlje sadrži kratak pregled onoga što je obavljeno u ovom radu, i dalje pravce razvoja implementiranog rješenja.

II. Teorijske osnove

A. *Digitalna televizija*

Televizija u širem smislu podrazumijeva prenos slike i zvuka od proizvođača, preko emitera, do gledalaca. Televizijski signal primarno služi da se prenese pokretna slika, zvuk i dodatne informacije važne za reprodukciju. Nerijetko se u okviru signala prenose i sadržaji koji nisu audio-video tipa, poput digitalnog teleteksta. Analogni televizijski signal je vremenom zamijenjen digitalnim TV signalom, a ta promjena je donijela poboljšanja u nekoliko segmenata, veći kvalitet audio i video signala, digitalnim kanalima je moguće prenijeti mnogo veše televizijskih programa i moguće je prenijeti dodatne sadržaje kao što je EPG koji će u ovom radu biti pretraživan u bazi podatak TV poslužioca.

Prednost digitalnog signala nad analognim jeste u primjeni digitalnih diskretnih algoritama obrade signala, pogotovo algoritama kodovanja (kompresije) video signala. Tek nakon efikasne primjene algoritama kompresije digitalni prenos dolazi u prednost u odnosu na analogni. Algoritmi kompresije omogućuju da se sa manje informacija prenese identičan video i audio sadržaj [4].

Efekat digitalne litice jedna je od najvažnijih osobina u

Radenko Banović – Fakultet Tehničkih Nauka, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: Radenko.Banovic@rt-rk.com).
Milan Z. Bjelica – Fakultet Tehničkih Nauka, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: Milan.Bjelica@rt-rk.com).
Darko Dejanović – RT-RK d.o.o., Narodnog Fronta 23a, 21000 Novi Sad, Srbija (e-mail: Darko.Dejanovic@rt-rk.com).
Milan Gvero – RT-RK d.o.o., Narodnog Fronta 23a, 21000 Novi Sad, Srbija (e-mail: Milan.Gvero@rt-rk.com).

digitalnoj televiziji. U slučaju pogoršanja kvaliteta prijema signala, kvalitet slike i zvuka se ne degradira postepeno (kao u slučaju analogne televizije), već su kvalitet slike i zvuka konstantni dok signal ne bude toliko loš da se ne može demodulisati, kada prijem u potpunosti prestaje.

B. Elektronski programski vodič - EPG

Elektronski programski vodič (eng. Electronic program guide) predstavlja skup informacija o programima iz određenog vremenskog intervala sa kanala dovedenih na TV Input. Informacije koje uobičajno čine EPG podatke su: naziv programa, kratak opis, vrijeme početka i kraja programa, naziv kanala za koji je program vezan, te nivo roditeljske zaštite.

C. Android platforma

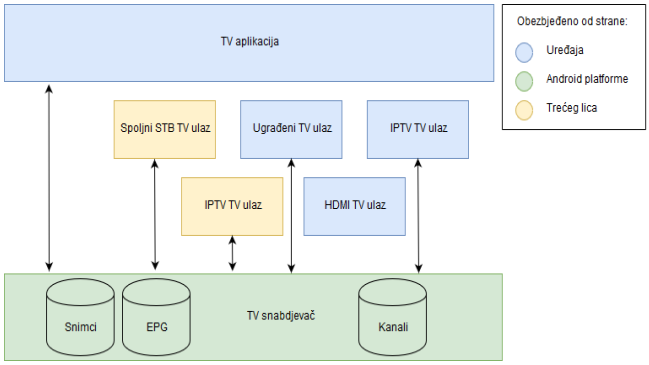
Android je slojeviti softver otvorenog koda (eng. open source) baziran na Linux jezgru namijenjen različitim uređajima. Ovaj rad je realizovan na Android platformi. Korištenje Linux jezgra omogućuje Androidu da iskoristi glavne sigurnosne karakteristike kao i proizvođačima uređaja da razviju hardverske upravljače za dobro poznato jezgro [5].

D. Android programska podrška za TV uređaje - TIF

Android programska podrška za TV uređaje definiše aplikativnu programsku spregu i standardizuje način implementacije dopremanja emitovanog sadržaja do TV aplikacije. TIF omogućuje implementaciju TV Input radnog okvira preko kojeg je moguće reprodukovati sadržaj sa mrežnog poslužioca i/ili iz DVB transportnog toka podataka kao i pretragu televizije uživo, i preporuke putem meta podataka objavljene od strane TV izvora [6].

TIF se sastoji od:

- TV aplikacija (eng. TV Application) - aplikacija koja rukuje zahtjevima korisnika;
- TV ulazni rukovalac (eng. TV Input Manager) – omogućuje TV ulazima da komuniciraju sa TV aplikacijom;
- TV Input – aplikacija koja predstavlja jedan izvor TV sadržaja;
- TV snabdjevač (eng. TV Provider) – baza podataka sa kanalima, programima i pratećim dozvolama;



Slika 1 - TV snabdjevač

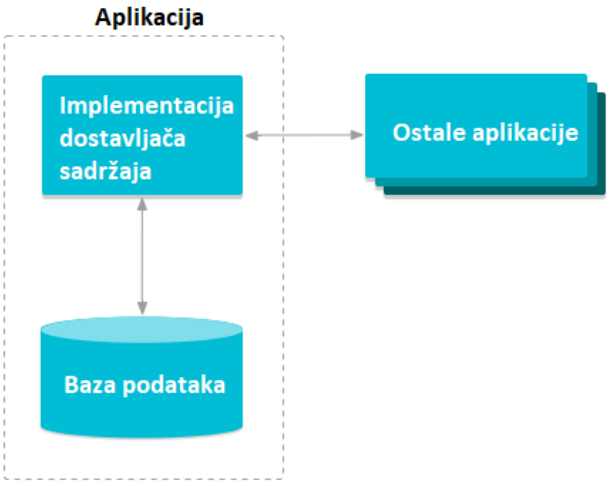
E. Google Asistent

Google Asistent je virtuelni lični pomoćnik razvijen od strane Google-a koji je dostupan i na Android TV uređajima od 2017. godine, a omogućuje dvostranu komunikaciju. Korisnici primarno komuniciraju sa Google Asistentom prirodnim glasom koristeći Google-ov algoritam za obradu prirodnog glasa, ali je i unos preko tastature takođe podržan. Pretražuje internet i aplikacije koje su lokalno instalirane ako su aplikacije prilagođene i dozvoljavaju globalno pretraživanje njihovog sadržaja, može podešavati hardverske komponente na uređaju, dodavati događaje u kalendar itd. Rezultati pretrage su predstavljeni kao kartice čijim se klikom ili dodirom otvara povezana stranica.

F. Dostavljač sadržaja (eng. Content Provider)

Dostavljači sadržaja omogućuju aplikacijama da upravljaju pravima pristupa podacima sačuvanim od strane njih samih, sačuvanih od strane drugih aplikacija i da omogući dijeljenje podataka sa drugim aplikacijama. Oni omogućuju mehanizam za definisanje sigurnosti podataka. Implementacija dostavljača sadržaja ima mnoge prednosti. Najvažnije je to što se može konfigurisati dostavljač sadržaja tako da se dozvoli drugim aplikacijama da bezbjedno pristupe i mijenjaju podatke aplikacije.

Dostavljači sadržaja predstavljaju odličan način apstrakcije, na primjer omogućavaju da se promijeni baza podataka u koju se smještaju podaci aplikacije, bez da to utiče na druge aplikacije koje se oslanjaju na pristup podacima. U tom slučaju moraju se napraviti izmjene samo u dostavljaču sadržaja, dok aplikacije koje pristupaju podacima ostaju nepromijenjene.



Slika 2 - Dostavljač sadržaja

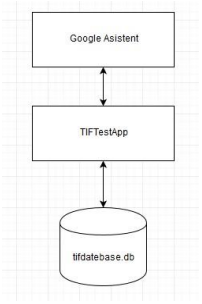
III. OPIS REALIZACIJE

TV Input radni okvir je potrebno proširiti tako da se omogući da se podaci iz baze podataka TV poslužioca nađu u rezultatima pretrage Google Asistenta.

Pored proširenja TV Input radnog okvira potrebno proširiti i testnu aplikaciju koja prikazuje sadržaj korisniku. Testna

aplikacija se oslanja na TV Input radni okvir. Ovo je neophodno da bi podaci iz baze podataka TV poslužioca bili globalno pretraživi, te da se iz rezultata pretraživanja jednim klikom može reprodukovati živi sadržaj kanala vezanog za program dobijen kao rezultat pretraživanja. Kao početna tačka izrade programskog rješenja korištene su dvije gotove aplikacije. Njih je potrebno nadograditi da bi omogućili Google Asistentu da prilikom pretrage u istu uključi i EPG sadržaj kanala dovedenih na TV Input, i to TIFTestApp i jednu implementaciju TV Input radnog okvira.

U toku istraživanja metoda za izradu programskog rješenja obavljen je jednostavan testni primjer najvažnijeg segmenta rješenja koji je služio za dokazivanje koncepta rješenja. Svrha ovakvog pristupa je da dokaže da je problem moguće riješiti na određen način. Testni primjer se odnosio na implementaciju nove testne baze podataka u okviru aplikacije TIFTestApp, te prilagođenja aplikacije Android pretražvačkoj sprezi koja treba da pročita informacije iz testne baze podataka i dostavi rezultate pretrage korisniku (Slika 3).



Slika 3 - Prototip testne aplikacije

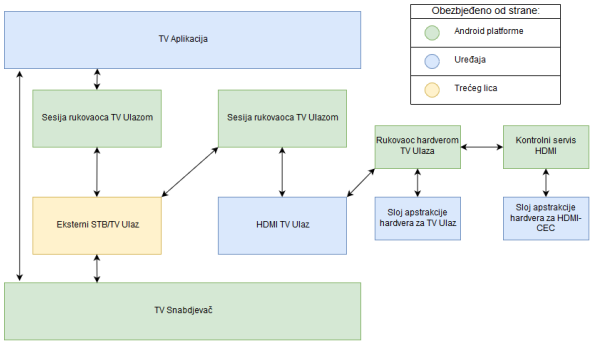
A. *Programsko okruženje i ciljna platforma*

Okruženje za izradu je Android Studio u programskom jeziku Java. Programski jezik Java prilagođen je potrebama i standardima Android operativnog sistema. Android studio razvojno okruženje omogućava laku ugradnju potrebnih alata i pruža širok spektar mogućnosti u realizaciji Android aplikacija, dok je SDK kolekcija alata koji pomaže u kreiranju Android aplikacija.

DTV prijemnik korišten pri izradi ovog rada je Android platforma bazirana na Marvell BG5CT čipsetu.

B. *Jedno rješenje TV Input radnog okvira*

TV Input popunjava TV sadržaj u bazu podataka TV poslužioca. TV Input predstavlja programsku reprezentaciju jednog izvora odakle se prima TV sadržaj (Slika 4). Može biti prisutno više TV Input radnih okvira.



Slika 4 -TV Input kreiran od treće strane

Rješenje TV Inputa koje je bilo potrebno nadograditi je imalo implementirano rukovanje tokovima audio i video podataka sa izvora TV sadržaja, skladištenje podataka o TV kanalima, rukovanje prevodima, itd. Dakle, imalo je skoro kompletnu implementaciju, ali nije imalo implementaciju skladištenja EPG podataka u bazu podataka TV poslužioca.

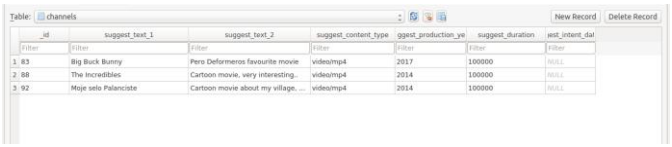
C. *TIFTestApp*

Druga aplikacija koju je potrebno izmijeniti jeste TIFTestApp, čija je funkcija da prezentuje TV sadržaj korisniku. U njoj korisnik može da bira TV Inpute (ukoliko ih ima više), da mijenja kanale, pregleda EPG sadržaj, te da gleda i sluša audio i video tokove izabranog kanala. Proširanje ove aplikacije podrazumijeva omogućavanje pretraživanje aplikacije od strane Google Asistenta, te korištenje API-ja TV Inputa radi dobavljanja informacija o trenutnom EPG sadržaju kanala na ulazu.

D. *Prototip kao dokaz validnosti koncepta rješenja*

Android TV koristi Android pretraživačku spregu da dobavi sadržaj od aplikacija i dostavi rezultate pretrage korisniku. Svaka aplikacija može biti prilagođena, i sadržaj aplikacije može biti uključen u rezultate pretrage. Aplikacija mora implementirati dostavljač sadržaja (eng. Content Provider) koji servira rezultate, kao i *searchable.xml* konfiguracioni fajl koji opisuje implementirani dostavljač sadržaja i ostale vitalne informacije Android TV-u. Izrada prototipa je prvi korak ka izradi programskog rješenja. Ideja je da se TIFTestApp aplikacija prilagodi na način da se omogući globalno pretraživanje kroz aplikaciju, i da se pripremi testna baza podataka sa nazivima kolona identičnim nazivima polja podataka pretraživačkog rukovaoca (eng. Search Manager). Kreirana je testna baza podataka za potrebe izrade prototipa pod nazivom *tiftestbase.db* (Slika 5).

Polja nose ova ime iz razloga što Android pretraživačka sprega očekuje baš takve nazive, pa je najlakše mapirati na nazive kolona koji se upravo tako zovu.



Slika 5 - Primjer testne baze podataka

Programsko rješenje se sastoji iz dva dijela, prvi dio predstavlja proširenje jednog rješenja TV Inputa implementacijom preuzimanja, parsiranja i skladištenja EPG podataka u bazu podataka TV poslužioca. Drugi dio predstavlja proširenje TIFTestApp aplikacije na način da, za razliku od prototipa, poslužuje EPG podatke koji su smješteni u bazi podataka TV poslužioca.

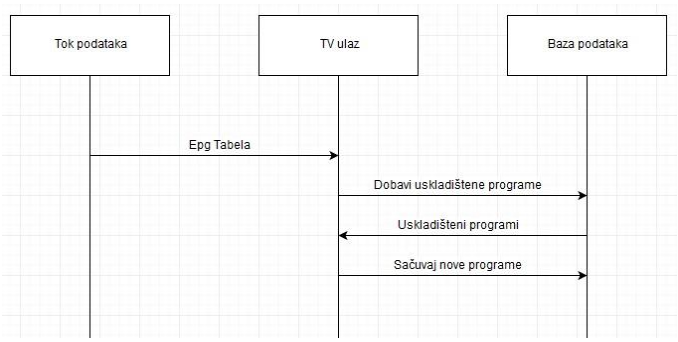
E. Proširenje TV Inputa

U TV Inputu treba da se iz ulaznog toka podataka izdvoje EPG podaci (naslov programskog događaja, opis, vrijeme početka i vrijeme završetka programskog događaja, kanal za koji je vezan događaj).

Da bi smjestili nove EPG podatke u bazu podataka TV poslužioca, neophodno je iz baze podataka dobaviti sve programske događaje u određenom vremenskom opsegu (u ovom slučaju 7 dana unaprijed i 36 sati unazad). Ovo je neophodno uraditi jer EPG podaci stižu periodično, i nema potrebe u bazu podataka smještati EPG podatke kada god tabela sa njima stigne, već samo onda kada stigne tabela sa događajima koji do tad nisu smješteni u bazu.

Kreira se upit bazi podataka kojim se dobavljaju uskladišteni programski događaji u određenom vremenskom opsegu, te se za svaki od novozaprimljenih događaja provjerava da li postoje u listi koja je popunjena podacima iz baze podataka, ako nije, događaj se stavlja u novu listu (array) koja će biti smještena u bazu podataka (Slika 6).

Ukoliko neki od programskih događaja postoji u bazi podataka, ali se sadržaj novopridošlog i programskog događaja smještenog u bazi podataka razlikuju, događaj se ažurira (umjesto uskladištenog sadržaja, u bazu podataka se smješta najnoviji sadržaj).



Slika 6 - Sekvencni dijagram skladištenja novih EPG podataka

F. Proširenje TIFTestApp

Aplikacija mora dostaviti Android TV-u polja podataka iz kojih se generišu predloženi rezultati pretrage nakon što korisnik ukuca karakter u dijalog za pretraživanje ili kaže ključne riječi Google Asistentu.

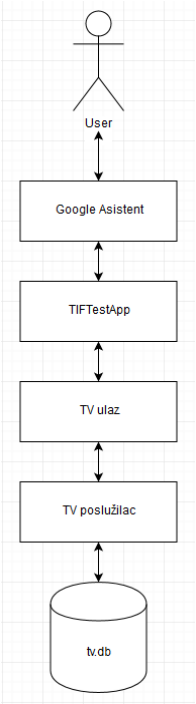
Da bi to omogućila, aplikacija mora implementirati dostavljač sadržaja (eng. Content Provider) koji servira prijedloge. Potrebno je kreirati i searchable.xml konfiguracioni fajl koji opisuje dostavljač sadržaja kao i ostale vitalne informacije Androd TV-u.

Pretraživački rukovaoc opisuje polja podataka koja očekuje, reprezentujući ih kao kolone lokalne baze podataka. Vrlo često su kolone u bazi podataka nazvane drugačije od polja pretraživačkog rukovaoca, pa je neophodno mapriati imena kolona lokalne baze podataka na nazive polja pretraživačkog rukovaoca.

Dostavljač sadržaja vraća rezultate pretrage u Android TV dijalog pretrage. Sistem šalje upit dostavljaču sadržaja svaki put kada Google Asistent bude prozvan. Dostavljač sadržaja pretražuje podatke i vraća pokazivač koji pokazuje na kolone izabrane kao prijedloge rezultata pretrage.

U *AndroidManifest.xml* datoteci dostavljač sadržaja ima poseban tretman, jer nije opisan tag-om kao ostali activity-ji već posebnim tag-om. Provider sadrži atribut koji se odnosi na ime klase u kojoj je implementiran dostavljač sadržaja, zatim atribut koji sistemu dobavlja informaciju o imenskom prostoru opisanog dostavljača sadržaja, a potrebno je i postaviti atribut kojim se dozvoljava da Android global search može koristiti podatke dobijene iz dostavljača sadržaja.

Da bi se moglo rukovati rezultatima pretrage, aplikacija mora da sadrži *searchable.xml* datoteku radi podešavanja prijedloga rezultata pretrage. Mora da sadrži atribut koji govori sistemu koji je imenski prostor dostavljača sadržaja, i on mora biti identičan kao isti takav atribut u *AndroidManifest.xml* datoteci. Prikaz komunikacije različitih elemenata sistema dat je na slici 7.



Slika 7 – Prikaz komunikacije različitih elemenata sistema

IV. TESTIRANJE

Prilikom izrade ovog rada obavljena su ispitivanja realizovanih modula i funkcionalnosti. Obavljene su dvije vrste ispitivanja: JUnit nezavisni testovi i ručno ispitivanje. JUnit ispitnim slučajevima su provjereni svi moduli opisani u ovom radu. JUnit ispitni slučajevi ne mogu da daju kompletan prikaz ispravnosti realizovanih funkcionalnosti zbog toga što ispituju da li je ispravna očekivana funkcionalnost na programskom nivou, i ne mogu da provjere da li se prikazala slika i slično, te su iz tog razloga obavljeni ručni ispitni slučajevi. Tabela JUnit ispitnih slučajeva se nalazi u tabeli 1.

TABELA 1
Uspješnost JUnit testova

Ispitni slučaj	**Rezultat**
Skladištenje EPG podataka	Prošao
Skladištenje EPG podataka koji već postoje u bazi podataka	Prošao
Upit po nazivu	Prošao
Upit po opisu	Prošao
Upit po nazivu za nepostojeće EPG podatke	Prošao

Ispitivanja vezana za Google asistent su obavljena ručno, odnosno Google asistent je pobuđivan ključnim riječima (nazivom ili kratkim opisom) EPG programa, što bi u rezultatima pretrage trebalo da prikaže sadržaj aplikacije, i da ponudi pokretanje aplikacije na kanalu za koji je EPG program vezan.

Zbog toga što platforma na kojoj su vršena testiranja nema mogućnost obrade govora, testiranja su vršena isključivo pokretanjem adb komande, unošenjem različitih upita kako naziva programskog sadržaja, tako i kratkog opisa programskog sadržaja. Ukoliko se nakon pokretanja adb komande sa upitom za programski sadržaj koji postoji u bazi podataka u rezultatima pretrage pojavi sadržaj čijim pokretanjem dolazi do pokretanja kanala koji je vezan za dati sadržaj, smatra se da je ispitni slučaj uspješno završen. Takođe, ukoliko se unese upit za sadržaj koji ne postoji u bazi podataka, i rezultati pretrage ostanu prazni, znači da je ispitni slučaj uspješno završen. Prikaz uspješnosti ručnih ispitnih slučajeva dat je u tabeli 2.

TABELA 2
Uspješnost ručnih testova

Ispitni slučaj	**Rezultat**
Football beast	Prošao
RT News	Prošao
News	Prošao
Dnevnik	Prošao
Sportski dnevnik	Prošao

V. ZAKLJUČAK

U ovom radu je realizovano skladištenje EPG podataka u bazu podataka TV poslužioca, te proširena aplikacija TIFTestApp radi omogućavanja globalne pretrage Google Asistenta kroz aplikaciju radi dobavljanja EPG podataka. Omogućena je reprodukcija živog programskog sadržaja kanala vezanog za programski sadržaj dobijen u dijalogu rezultata pretrage. Rješenje je realizovano na Marvell BG5CT platformi oslanjajući se na Android operativni sistem sa Android programskom podrškom za TV uređaje (TIF). Rješenje je ispitivano na ciljnoj platformi, i testiranjem je utvrđena funkcionalnost rješenja. Razvoj Android platforme i proširenje skupa njenih funkcionalnosti pruža mogućnost za dalju nadogradnju i poboljšanje datog rješenja. Jedan od pravaca daljeg razvoja programskog rješenja bi moglo biti proširenje obje aplikacije na način da se omogući skladištenje živog TV programskog sadržaja, te nakon pretraživanja EPG podataka, pokretanje baš tog programskog sadržaja koji je prethodno emitovan i uskladišten pomoću snimača kanala.

ZAHVALNICA

Ovaj rad je djelimično finansiran od strane Ministarstva za prosvetu, nauku i tehnološki razvoj Republike Srbije, na projektu broj: TR36029.

ABSTRACT

This paper presents one solution of extending the TV Input Framework with functionalities of the Google Assistant package. TV Input is a program representation of a single source from which it receives TV content, and fills content into a TV provider's database. The expansion of the TV Input refers to customizing the search and display of the EPG (electronic program guide) data stored in the TV provider database so that they appear in Google Assistant search results.

Extension of TV Input framework with Google Assistant functionalites in Android environment

Jedno rešenje reprodukcije multimedijalnog sadržaja na Android Things platformi

Marijana Gligorić, Vladimir Nešić, Nikola Vranić, Miloš Subotić, Đorđe Glišić

Apstrakt— **U poslednjih deset godina širi se upotreba digitalne televizije, razvijaju tehnologije i pojavljuju novi uređaji. Takođe se pojavljuju i zahtevi za novim funkcionalnostima od strane korisnika. Razvijanje aplikacije za gledanje televizije na set top box uređaju je nešto što smo do sada već videli. Pored toga, to izaziva određene komplikacije ako je u pitanju samostalan inženjer zbog nedostupnosti uređaja na kome bi se razvijale aplikacije ili nedostatka root prava na istim. Kao odlično inovativno rešenje u ovakvoj situaciji nameće se platforma za razvijanje Internet of Things aplikacija koju je ponudio sam Google: Android Things. Ovaj rad predstavlja konkretno rešenje reprodukcije televizijskog sadržaja korišćenjem pomenute platforme. Za implementaciju rešenja korišćen je uređaj Rasberry Pi 3 Model B.**

Ključne reči **— Raspberry Pi, Android, Digital Video Broadcast, Dynamic Adaptive over HTTP, Internet of Things.**

I. Uvod

Vreme u kojem živimo danas veoma je teško zamisliti bez mobilnih uređaja, posebno bez mobilnih telefona. Njihovo postojanje beleži nešto manje od pola veka, ali njihov razvoj pokazuje ogroman napredak za kratko vreme. Predviđa se da će do 2020. godine čak devedeset posto populacije posedovati mobilni telefon. Dva trenutno najaktuelnija operativna sistema koja se koriste za razvoj mobilnih aplikacija su Android i IOS. Za razvoj Android aplikacije se odlučilo 47% programera, dok IOS preti da ga prestigne sa 31%. Što se tiče procenta korisnika koji na svom uređaju poseduju Android sistem u odnosu na one koji koriste IOS on okvirno iznosi 70 prema 30 respektivno [1].

U poslednje vreme sve aktuelnija tema jeste Internet of things. Internet of things uređaji predstavljaju fizičku arhitekturu sa delom programske podrške koja je ugrađena u njih i koja ima pristup internetu. Jedna od ključnih razlika izmedju Internet of Things uređaja i tradicionalnih uređaja jeste u tome što pametnim uređajima mi zadajemo funkciju koju želimo da nam izvrše i na taj način vršimo interakciju sa samim uređajem. Internet of things uređaji sami prikupljaju podatke, selektuju ih, šalju preko interneta na dalju obradu i na taj način vrše funkciju za koju su namenjeni. Neki od najpopularnijih projekata iz ove kategorije su: pametni gradovi, pametni domovi, briga za stara lica i slično.

Jedna od stvari koje su neophodne za pravljenje programa jeste operativni sistem. Google je ponudio rešenje u vidu Android Things platforme i ponudio je uređaje na kojima ovaj sistem može da se koristi. Trenutno najprodavaniji i najčešće korišćeni uređaj jeste Raspberry Pi. Ovaj uređaj će se koristiti i za realizaciju rešenja predstavljenog u ovom radu.

Još jedan pojam sa čijom se upotrebom susrećemo duže od mobilnih uređaja jeste televizija. Ranije je gledanje televizijskog sadržaja bilo usko povezano sa televizorom kao uređajem preko kojeg je to moguće ostvariti. Danas je poznato da je televizijski prenos moguć i korišćenjem mobilnih telefona. Velika prednost jeste to što se prilikom potpisivanja ugovora sa odgovarajućim operaterom i dogovora o pretplati na određen broj kanala dobija korisničko ime i lozinka kojom je moguć pristup pretplaćenom sadržaju sa bilo koje platforme čije korišćenje omogućava operater. Upotreba Android platforme na namenskom uređaju podrazumeva prilagođenje potrebama i ograničenjima konačnog proizvoda, i predstavlja složen zadatak koji zahteva razumevanje unutrašnje arhitekture Androida, prilagođavanje slojeva operativnog sistema mogućnostima platforme kao i Linux jezgra na koji se Android oslanja.

Do sada su istraživanja rađena u sferi TV industrije ka korišćenju STB uređaja koji bi koristili Android kao operativni sistem [2]. Razvoj je proširen na internet ka streaming servisima i IPTV rešenjima. U okviru Internet of Things primena, jedan uži skup ali izuzetno aktivan predstavljaju pametne kuće i integracija kućnih senzora i uređaja u mrežu preko koje mogu da razmenjuju informacije. Podskup istraživanja je išao u smeru integracije TV prijemnika u IoT mrežu radi kontrole aparata, osvetljenja, vrata i prozora, kućnih aparata i sl [3]. U primeni IoT rešenja, postoji čitav niz uređaja na tržistu, najrazličitijih namena, od senzora koji se napajaju običnim baterijama do rutera koji mogu da prikupljaju podatke sa senzora i kontrolišu iste. Jedna popularna platforma za razvoj IoT rešenja je i Raspberry Pi. Kompanija Google je prepoznala značaj i mogućnosti ovih modela i njihovu primenljivost u IoT industriji kada je učinila dostupnim Android Things operativni sistem za ove uređaje. Ovaj rad za cilj ima da dokaže da je već sada moguće dobiti uređaj koji se može koristiti kao digitalni TV prijemnik, od IoT uređaja na kome se izvršava Android operativni sistem.

U nastavku će biti dat pregled arhitekture i odlika sistema, sledi opis rešenja, zatim testiranje i na kraju zaključak i literatura.

II. ANDROID OS

Kao vodeći operativni sistem za mobilne uređaje na tržištu, ali i za ostatak potrošačke elektronike, Android OS sadrži specifičnu arhitekturu koja je kompleksna i podeljena u nekoliko suštinskih slojeva.

Arhitektura Android Sistema se sastoji od četiri sloja i to su:

1. Sloj jezgra
2. Radni sloj
3. Sloj programskih okvira
4. Aplikativni sloj

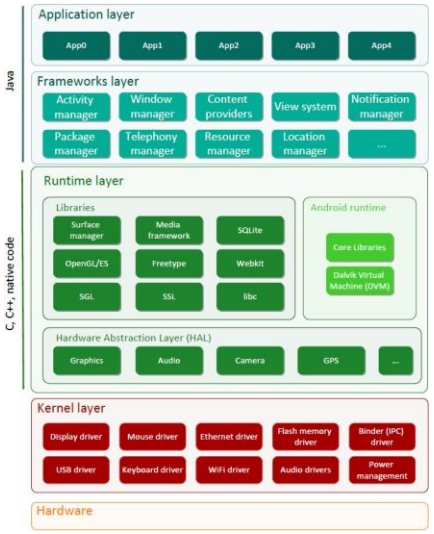
Sloj jezgra je zadužen za sledeće funkcionalnosti: rukovanje fizičkim i logičkim resursima ciljne platforme, rukovanje i pokretanje programskih procesa i obezbeđivanje konteksta izvršavanja, rukovanje sistemom datoteka i realizacija prava pristupa. Jezgro Androida je Linux, uz modifikacije specifične za Android, koje obezbeđuje dodatne funkcionalnosti neophodne za ispravan rad ostatka Androida. Modifikacije su zapravo skup zakrpa koji se primenjuje na izvorni kod Linux jezgra.

Radni sloj predstavlja skup različitih komponenata koje se izvršavaju u formi mašinskog koda na ciljnoj platformi. Namena ovog sloja jeste da obezbedi funkcionalnosti za više slojeve, obezbeđujući optimalne performanse.

Ovaj sloj se sastoji od sloja za apstrakciju i prilagođenje sistema, skupa biblioteka u izvršnom obliku i jezgra za izvršavanje Android aplikacija. Namena podsloja za apstrakciju sistema je obezbeđivanje uniformnog programskog sloja višim programskim slojevima prilagođavanjem sistemskih funkcija. Cilj uvođenja ovog sloja je izolacija viših programskih slojeva od ciljne platforme, oslanjajući se isključivo na obezbeđenu programsku spregu. U radnom sloju je enkapsuliran i značajan broj biblioteka čija je zajednička osobina to što su direktno izvršive na ciljnoj platformi. U ovaj sloj se ubacuju i biblioteke koje obezbeđuje proizvođač platforme i koje obavljaju funkcije karakteristične za datu platformu. Poslednja komponenta u radnom sloju je okruženje za izvršavanje Android aplikacija. Android je do verzije 5.0 posedovao svoju implementaciju Java virtuelne mašine Dalvick, koju je kasnije zamenio Android Runtime – ART. Glavnu motivaciju za razvoj ART-a predstavlja veće iskorišćenje resursa hardvera i stvaranje novog programskog okvira za držanje koraka sa daljim razvojem hardvera, pre svega prelaskom na 64-bitne procesore [4].

Sloj programskih okvira predstavlja spregu ka korisničkim aplikacijama. Njegov zadatak je da obezbedi adekvatnu predstavu funkcionalnosti sistema u formi Java klasa i programskih sprega. Sloj definiše programsku spregu ka aplikacijama kao skup Java klasa. Implementacija tih klasa je većinom jednostavna i brzo se završava pozivom funkcije iz radnog sloja. Mehanizam koji se koristi za integraciju sa izvršnim kodom u radnom sloju je JNI, i o njemu će biti reči kasnije u tekstu.

Najviši sloj Androida predstavljaju korisničke aplikacije. Android aplikacije se tipično razvijaju u programskom jeziku Java, oslanjajući se na Java programsku spregu koju obezbeđuje sloj radnog okvira. Postoji mogućnost da se Android aplikacije razvijaju i u drugim programskim jezicima, ali većinom nisu toliko dobro podržani kao Java. Na slici je prikazana arhitektura Android operativnog sistema.



Sl. 1. Arhitektura Android operativnog sistema

III. OPIS REŠENJA

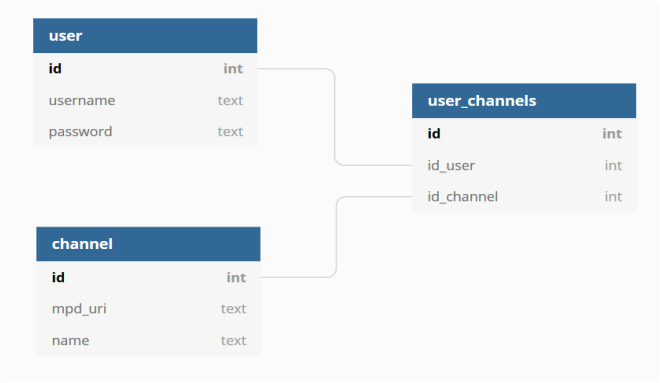
Sistem se sastoji iz dve aplikacije: Java aplikacija koja sadrži bazu podataka i grafički interfejs i native aplikacija pomoću koje se video skida sa MPD linka i emituje na odgovarajući način. Za uređaj na kojoj se razvija aplikacija izabran je Raspbery Pi 3 Model B. Koristi 64-bitni procesor sa četiri jezgra i poseduje memoriju od 1 GB. Celokupna instalacija Android operativnog sistema na uređaj je trivijalan posao koji se sastoji iz par koraka. Na slici je prikazan korišćeni uređaj.

Sl. 2. Raspberry Pi 3 Model B

Java aplikacija je realizovana kroz okruženje Android Studio. Jedna od tih prednosti jeste SQLite, kao podrška za rad sa bazom podataka. SQLite je ugrađeni DBMS u svaki Android uređaj.

Korišćenje SQLite baze podataka na Androidu ne zahteva

nikakve dodatne instalacije, te nije potrebno pokretanje pozadinskih procesa. Takođe, kako on nema klijent-server arhitekturu i to omogućava višestruki i istovremeni pristup podacima, jer se kod izvršava pri pozivu. Konkretno, u ovom radu klase za rad sa bazom podataka smeštene su u paket *database* i to su klase koje predstavljaju projekciju tabela kanal, korisnik i kanal-korisnik iz baze podataka. Respektivno, to su klase koje sadrže podatke o korisnicima, kanalima i vezi između korisnika i kanala kojima oni imaju pristup.



Sl. 3 Dijagram klasa u bazi podataka

Aplikacija sadrži nekoliko scena: scena za prijavljivanje na sistem, scene sa porukama o grešci prilikom unosa netačne lozinke ili korisničkog imena i scena sa grafičkim elementom za pregled video sadržaja i izborom kanala. Korisnik će pri instalaciji aplikacije već posedovati korisničko ime i lozinku koju je dobio od operatera kod kojeg je pretplaćen na paket kanala, što će iskoristiti prilikom prijavljivanja na sistem, prikazano na slici 3.

Sl. 4. Prijavljivanje na sistem

U zavisnosti od uspešnog ili neuspešnog scenarija prilikom logovanja korisnik se upućuje respektivno na stranicu sa kanalima koje može da prati ili na stranicu sa porukom o grešci.

Nakon uspešne prijave na sistem korisniku se pojavljuje početni ekran koji sadrži listu kanala na koje je korisnik pretplaćen kao i ravan, grafički element koji omogućava pregled video sadržaja u Android aplikacijama. Na ovom ekranu korisnik ima mogućnost da klikne na sliku koja predstavlja određeni kanal i u tom trenutku počinje reprodukcija sadržaja koja se odnosi na taj kanal, prikazano na slici broj pet.

Sl. 5. Biranje kanala

Native aplikacija je realizovana koristeći teoriju iz adaptivnih audio i video tokova. Adaptivni bitrejt prenos je tehnika koja se koristi za prenos multimedijalnog sadržaja putem kompjuterske mreže. Ranije se za ovaj prenos koristio protokol RTP, dok se danas koristi HTTP. Kako bi korisnicima pružili sadržaj koji je adaptivan u odnosu na internet konekciju velike kompanije su predložile svoja rešenja. Tako je Apple predložio HTTP Live Streaming (HLS) koji je podržan na njegovoj platformi IOS, kao i radni okvir za reprodukciju QuickTime X. Microsoft pokušava sa Smooth Streaming koji predstavlja još jedan od servisa u ISS paketu. Ipak među svima njima izdvojio se DASH [5], kao jedino rešenje koje je internacionalni standard za obezbeđivnje neprekidnog videa, ali na uštrb kvaliteta slike.

DASH jeste tehnologija koja omogućava da se multimedijalna datoteka deli na više delova koji se zatim koristeći HTTP protokol dostavljaju klijentu. Pored samih segmenata video datoteke prenose se i podaci koji nose informacije o samim segmentima. Segmenti mogu da sadrže bilo koju vrstu multimedijalnih podataka u bilo kom formatu. Preporuka je da se koristi MPEG4 datoteka, odnosno MPEG2 transportni tok za prenos tih datoteka. DASH koristi HTTP infrastrukturu koja se zapravo koristi za dostavljanje svakog WWW sadržaja što dozvoljava uređajima kao što su televizor konektovan na internet, digitalni TV prijemnici ili čak Raspberry Pi da koriste ovu tehnologiju na lak način.

Ideja native dela aplikacije jeste da se multimedijalni sadržaj, koji predstavlja prenos uživo, skida sa jedne od MPD veza, zatim skladišti i na kraju prikazuje korisniku. Za tu potrebu ključnu ulogu igraju dve biblioteke libplayer i libdash. Njihov način dodavanja u Android Studio i prevođenje u sistemu je opisan kroz makefile-ove. Paralelno se pomoću libdash biblioteke dohvata sadržaj MPD veza, a nakon preuzimanja segmenta on se šalje odgovarajućem objektu koji je zadužen za njegovu reprodukciju.

Najpre, objekat se kreira kao instance klase PlayerHandle, koja je jedna od klasa biblioteke libplayer. Zatim sledi postavljanje u početno stanje tog objekta odgovarajućim parametrima. Nakon ovoga, u klasi Stream koja proširuje klasu IAdaptionStreamDownloaderListener se implementiraju određene funkcionalnosti u odgovarajućim nasleđenim metodama za primanje sadržaja, početak skidanja i neuspeh pri skidanju. U metodi za primanje skinutog sadržaja između ostalog se obavlja i dohvatanje informacije o skinutom sadržaju odnosno da li se radi o audio ili video tipu segmenta i na osnovu tog podatka šalje se podatak funckiji feedPlayer iz

čijeg imena možemo zaključiti da se radi o funkciji koja služi za prikaz skinutog sadržaja.

IV. TESTIRANJE

Da bi se proverila ispravnost aplikacije izvršena je dinamička provera programa izvođenjem konačnog broja testova i upoređivanjem sa očekivanim ponašanjem programa. Osim same provere cilj testiranja je i stvaranje određenog nivoa sigurnosti da program radi ono što je opisano u zahtevima. U ovom radu kod testiranja fokus je na delu aplikacije pisanom na programskom jeziku Java. Sama aplikacija je testirana na dva načina: automatski i manuelno. Korišćeni su JUnit i PowerMockito [6] radni okvir koji pruža usluge za testiranje Android aplikacija. Od metoda za testiranje koje pruža ovaj radni okvir korišćen je metod koji je generalno najviše u upotrebi – assertion sistem. Testovi koji su pisani za ovaj sistem su koristeći ovaj metod poredili vrednosti testiranih metoda sa očekivanim. Rezultati testova su prikazani u tabeli.

Tabela I Rezultati testova

Opis grupe testova	Rezultat
Prijava i odjava korisnika	Prošli
Reprodukcija MP4 sadržaja	Prošli
Prikazivanje sadržaja različitog kvaliteta	Prošli

Što se tiče automatskog testiranja napisane su između ostalih i metode koje testiraju prijavljivanje korisnika na sistem sa različitim parametrima.

Manuelno testiranje je, pored standardnog načina uz pomoć testera, izvršeno i korišćenjem programa Monkey. On predstavlja alatku koja se pokreće na uređaju i koja generiše pseudo-slučajne ulaze i tako simulira manuelno testiranje aplikacije. Testiranje je dodatno proverilo ispravnost aplikacije i demonstriralo kako aplikacija radi u različitim slučajevima.

V. ZAKLJUČAK

Današnji korisnici uređaja potrošačke elektronike su sofisticiraniji od svojih prethodnika u kontekstu da više obraćaju pažnju na detalje vezane za doživljaj korišćenja datih uređaja. Proizvod s toga treba prilagoditi korisnicima, ali i potrebama na tržištu.

Ostvarena je ideja da se podigne poslednja verzija Android Things sistema na pomenutoj ploči i napiše aplikacija za reprodukciju sadržaja, koja će se sastojati iz native aplikacije koja se oslanja na postojeći DTV sprežni sloj, koja reprodukuje TV sadržaj preko mreže i nakon toga se integriše preko JNI sloja sa Java aplikacijom. Sve ovo je na kraju potvrđeno rezultatima testiranja.

U odnosu na referentni rad [3], može se složiti sa tim da Raspberry Pi nudi bolje mogućnosti od platformi LG i Panasonic, zato što Raspberry Pi nema striktno ograničeni API koji ne bi dozvoljavao pokretanje aplikacija u pozadini, čime bi se smanjila mogućnost korišćenja ovih platformi u veoma važnoj ulozi – obrada podataka.

Planovi za dalji razvoj rada su usmereni ka snimanju Widevine [7] zaštićenog sadržaja, kao i dodavanje podrške za snimanje drugih vrsta dinamičkih adaptihivnih tokova podataka, prvenstveno HLS [8].

ZAHVALNICA

Ovaj rad je delimično finansiran od strane Ministarstva za prosvetu, nauku i tehnološki razvoj Republike Srbije, na projektu broj: TR32029.

ABSTRACT

In the last ten years, the use of digital television has been expanding, technologies have been developed and new devices have emerged. There are also requests for new functionalities by users. Developing an application for watching TV on a set top box is something we have already seen before. In addition, this causes some complications if it is a standalone engineer because of the inaccessibility of the device in which applications or the lack of root rights will be developed on the same. As an excellent innovative solution in this situation, a platform for developing the Internet of Things application, offered by Google itself: Android Things. This paper presents a concrete solution for the reproduction of television content using this platform. For the implementation of the solution, the Rasberry Pi 3 Model B.

ONE SOLUTION OF REPRODUCTION MULTIMEDIA CONTENT ON INTERNET OF THINGS DEVICE

Jedno rešenje zaštite podataka na Linux Set Top Box uređajima

Aleksandra Keča Despotović, Boris Mlikota, Mario Radonjić, Miroslav Bako, *Member, IEEE*

***Apstrakt*— U ovom radu je prikazano jedno rešenje implementacije zaštitnog sistema za Linux Set Top Box (STB) uređaje. Cilj ovog rada je da prikaže kako je moguće, korišćenjem Linux kontejnera (eng. Sandboxing), postići veći nivo zaštite uređaja, i na koji način je moguće izolovati kritične procese od neželjenog pristupa podacima. Dat je kratak osvrt na teorijske osnove korišćenja Linux kontejnera, predlog implementacije ove metode na STB-u, kao i prikaz uticaja korišćenja ove metode na ukupne performance sistema.**

***Ključne reči*— STB; Set Top Box; TV; Linux kontejneri; LXC; Kernel namespace; CAS;**

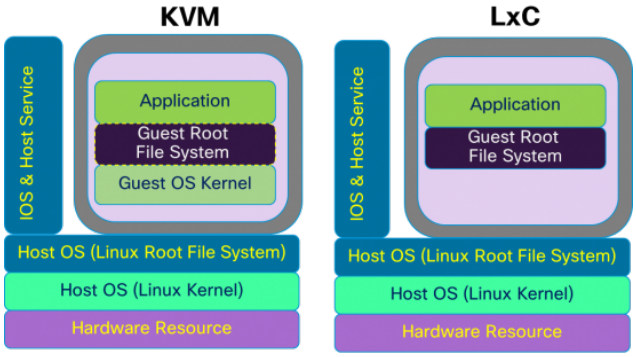
I. Uvod

Razvojem digitalne televizije sve više se javlja potreba za zaštitom tv sadržaja od neovlašćenog pristupa. Tokom vremena razvijeni su brojni metodi zaštite, u vidu kodovanja signala, ali većina tih metoda nije pružala dovoljan nivo zaštite u slučaju poverljivih podataka. Kako je rasla potreba za sve većom zaštitom podataka, tako se povećavao broj zloupotreba, u vidu zaobilaženja zaštitnih sistema i dobavljanja podataka od strane lica koja tim podacima nemaju dozvoljen pristup. Razvojem i komercijalizacijom digitalne televizije razvijali su se i različiti tipovi zaštite digitalnog televizijskog signala. U digitalnoj televiziji, kodovanje je uspešan način zaštite video i audio sadržaja, međutim postoji potreba da se procesi, u kojima se obavlja dekodovanje, zaštite od neželjenog pristupa. Kako bi dekodovanje signala unutar procesa ostalo zaštićeno, bilo je potrebno pronaći način kako bi se i okruženje, u kome se vrše procesi dekodovanja signala, učinilo bezbednim i zaštićenim. Da bi bio sprečen neovlašćen pristup bilo kom delu sistema, neophodno je obezbediti maksimalan nivo zaštite, i tako na uspešan način izolovati procese koji imaju pristup podacima koje je potrebno zaštititi. Jedan od mehanizama izolacije delova sistema, koji su razvijeni na Linux platformi, je korišćenje linux kontejnera.

II. Teorijske osnove

Linux kontejneri pružaju mogućnost izolovanja željenih procesa u logičke celine, takozvane "kontejnere", kako bi obezbedili veću izolaciju između procesa i podataka koji se nalaze u različitim kontejnerima. Cilj je postići veći nivo zaštite osetljivih podataka, bez nepotrebnog usporavanja sistema.

Linux kontejneri omogućavaju stvaranje okruženja koje je veoma slično virtualnoj mašini, ali bez opterećenja sistema koje unosi vitrualna mašina, u vidu pokretanja sopstvenog kernela i simulacije hardwera. Poređenje arhitekture Linux kontejnera i virtualne mašine prikazan je na slici 1.



Sl. 1. Poređenje arhitekture virtualne mašine i Linux kontejnera

Da bi se iskoristile prednosti linux kontejnera, koriste se već postojeće osobine linux kernela, kao što su *namespace*-ovi, kontrola pristupa i kontrolne grupe.

A. Kernel namespace

Namespace je način na koji linux kernel izoluje ili virtualizuje sistemske resurse od jednog ili više procesa. Primeri resursa koji mogu biti virtualizovani su proces ID, hostnames, user ID, pristup mreži, međuprocesna komunikacija i filesystem.

Namespace-ovi su mehanizmi kernela koji obezbeđuju izolaciju procesa (ili grupe procesa) i vizuelizaciju sistemskih resursa za te procese. Postoji sedam vrsta *namespace*-ova:

- MNT (Mount *namespace*) - kontroliše mount point
- PID (Proces ID *namespace*) - kreira PID-ove za svaki proces, koji ne zavise od drugih *namespace*-ova, pa će proces nakon kreiranja imati poseban PID za svaki *namespace*
- NET (Mrežni *namespace*) - virtualizuje mrežu na način da je svaki mrežni interfejs, virtualni ili fizički, u jednom trenutku dostupan samo u jednom *namespace*-u, a svaki *namespace* ima jedinstvene IP adrese, routing tabele, liste socketa, firewall...
- IPC (Međuprocesni komunikacioni *namespace*) - Interprocess communication sprečava procese u

Aleksandra Keča Despotović – RT-RK.doo, Narodnog Fronta 23a, 21000 Novi Sad, Srbija (e-mail: Aleksandra.Keca-Despotovic@iwedia.com)
Boris Mlikota - RT-RK.doo, Narodnog Fronta 23a, 21000 Novi Sad, Srbija (e-mail: Boris.Mlikota@rt-rk.com)
Mario Radonjić - RT-RK.doo, Narodnog Fronta 23a, 21000 Novi Sad, Srbija (e-mail: Mario.Radonjic@iwedia.com)
Miroslav Bako - RT-RK.doo, Narodnog Fronta 23a, 21000 Novi Sad, Srbija (e-mail: Miroslav.Bako@rt-rk.com)

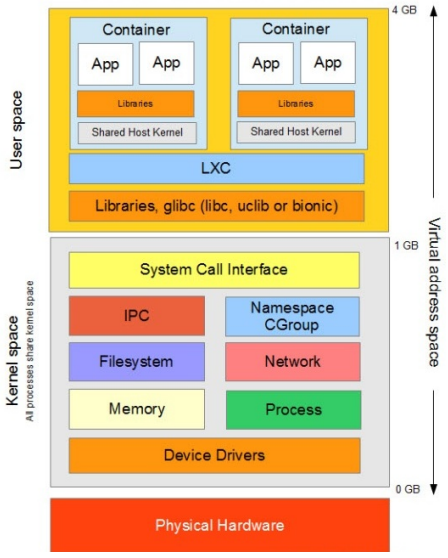
različitim IPC *namespace*-ovima da koriste iste načine komunikacije u isto vreme
- UTS (UNIX timesharing system *namespace*) - omogućava da sistem deluje kao da ima različita host i domain imena za različite procese.
- USER (Korisnički *namespace*) – pruža mogućnost da svaki kontejner ima sopstvenog korisnika (User ID) ili grupu (Group ID), kako bi se omogućila root-prava pristupa unutar kontejnera
- CGROUP (Control group *namespace*) - sprečava da drugim *namespace*-ovima bude vidljivo kojoj kontrolnoj grupi neki proces pripada

Namespace-ovi predstavljaju osnovni koncept linux kontejnera. Linux sistem inicijalizuje po jednu instancu svakog tipa *namespace*-a, a nakon inicijalizacije moguće je dodatno kreiranje željenih *namespace*-ova.

Kako bi korišćenje ovih osobina kernela, u cilju kreiranja linux kontejnera, bilo brže i jednostavnije za korisnika, ove osobine i funkcionalnosti su grupisane u jedinstven paket, koji se naziva LXC (LinuX Container).

B. LXC (Linux Container)

LXC je interfejs koji je kreiran radi jednostavnijeg i bržeg korišćenja linux kernel funkcionalnosti. Pomoću jednostavnog interfejsa i alata, omogućava linux korisnicima lak i brz način kreiranja i upravljanja linux kontejnerima. LXC se sastoji od alata, template-a i biblioteke, koji čine sloj softvera koji je prilagodljiv i podržava sve funkcionalnosti kernela, na koji se oslanja. Slikoviti prikaz LXC arhitekture prikazan je na slici 2.



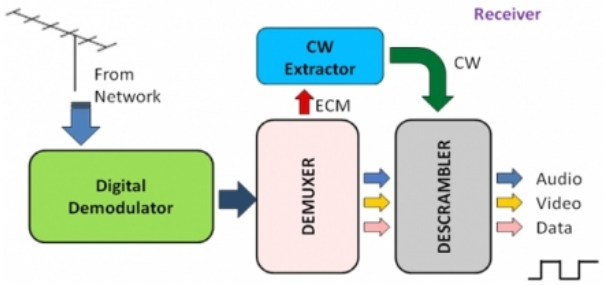
Sl. 2. LXC arhitektura

Uz pomoć LXC-a omogućena je izolacija procesa od neželjenog pristupa, od strane neovlašćenih korisnika ili drugih procesa. Linux kernel obezbeđuje CGROUP funkcionalnost koja omogućava ograničenje i određuje nivoe prioriteta pojedinih resursa (CPU, memorija, I/O blok, mreža...), bez potrebe za startovanjem virtualne mašine, kao i *namespace* funkcionalnost koja omogućava totalnu izolaciju operativnog okruženja, sa tačke gledišta aplikacije. Korišćenjem LXC-a moguće je postići nivo virtuelizacije operativnog sistema na osnovu virtualnog okruženja, koje se sastoji iz sopstvenih procesa i mrežnog prostora, umesto korišćenjem standardnih virtualnih mašina. Prednost korišćenja LXC-a, u poređenju sa sličnim rešenjima, kao što su Linux-VServer ili OpenVZ, je to što korišćenje LXC-a ne zahteva nikakve izmene u kernelu, već koristi mehanizme koji su već ugrađeni u kernel.

III. METODE ZAŠTITE PODATAKA NA STB UREĐAJIMA

U sklopu DVB (Digital Video Broadcasting) standarda definisan je standard za kontrolu pristupa, tzv. CAS (Conditional Access System), koji definiše metode zaštite digitalnog televizijskog signala. Na osnovu standarda, definisani su određeni uslovi koje je potrebno ispuniti, kako bi bio omogućen pristup digitalnom sadržaju od strane sistema koji vrši kontrolu pristupa. Zaštita podataka je ostvarena kombinacijom skremblovanja i kodovanja. Podaci se skrembluju pomoću 48-bitnog zaštitnog ključa, zvanog control word, koji se automatski generiše i koji u trenutku deskremblovanja mora biti poznat, a može se menjati i više puta u minuti. Da bi se deskremblovanje odvijalo pravovremeno i bez zastoja, zaštitni ključ mora biti dostupan u trenutku kada je potreban. Kako bi ključ bio zaštićen prilikom prenosa do prijemnika, potrebno je da se koduje kao ECM poruka (Entitlement Control Message). Nakon prijema, ključ je potrebno dešifrovati, što se postiže pomoću EMM poruke (Entitlement Management Message). Sadržaj ECM i EMM poruka nije standardizovan, već zavisi od sistema zaštite koji se koristi. Trenutno, na trzistu postoji više CAS-ova, kao sto su VideoGuard, Irdeto, Nagravision, Conax, Viaccess, Cisco, Mediaguard...

Na slici 3 prikazana je blok šema korišćenja CAS-a na STB uređaju.



Sl. 2. CAS na STB uređaju

Ovi sistemi se zasnivaju na prijemu ECM i EMM poruka, koji se dopremaju na STB preko mreže, pa samim tim zahtevaju određeni nivo sigurnosti i izolacije procesa u kojima se vrši prijem ovih važnih podataka.

IV. KORIŠĆENJE LXC-A NA STB UREĐAJIMA

U cilju bolje zaštite podataka koji se smatraju osetljivim, na STB uređajima, koji koriste linux platformu, poželjno je koristiti neku metodu izolacije delova sistema. Jedna od metoda zaštite koja je realizovana u ovom radu je korišćenje

LinuX Container-a (LXC-a). Podaci, koji se smatraju osetljivim, moraju biti izolovani u poseban kontejner, koji ne sme da ima pristup mreži (osim interprocesne komunikacije), niti da prima podatke iz izvora koji se smatraju nepouzdanim.

U slučaju korišćenja kontejnera ne smeju postojati task-ovi koji imaju root/administrativne privilegije. Takođe, kontejneri ne smeju imati direktan pristup informacijama o drugim kontejnerima, kako bi se obezbedila izolacija. Ukoliko postoji potreba za razmenom informacija između dva kontejnera, mora se obezbediti poseban kanal za razmenu podataka (zauzeti memorijski prostor – buffer), a podaci koji se razmenjuju moraju biti formatirani na unapred definisan način, tj da ispoštuju unapred definisan komunikacioni protokol. Ovi kanali za razmenu podataka između izolovanih kontejnera su najslabija tačka sistema, pa ih je potrebno obezbediti.

V. Primer korišćenja LXC-a

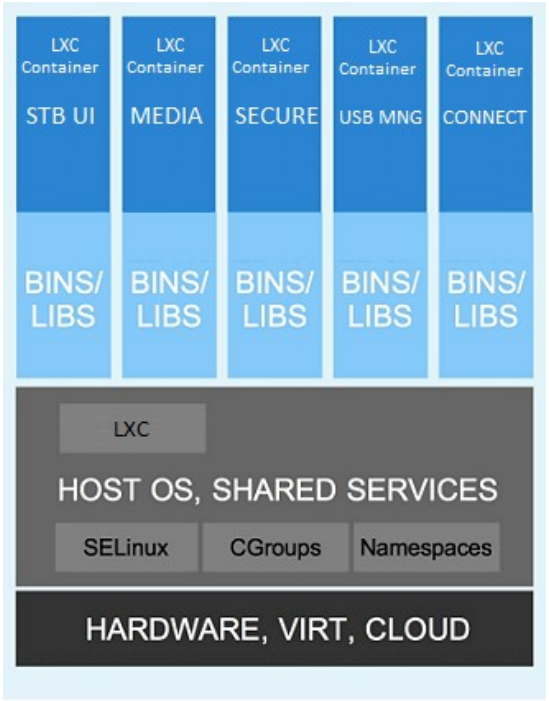
Kako se ne bi degradirali robusnost i pouzdanost sistema, program je potrebno podeliti na manje celine, tako što će se u kontejnere grupisati komponente koje imaju sličnu funkcionalnost i sličan nivo potrebne zaštite. Prilikom definisanja nivoa zaštite određenog kontejnera, treba voditi računa o sledećem:

- Server/klijent – Serverske funkcije su vidljive i dostupne spolja, pa postoji veća potreba za zaštitom u odnosu na klijentske funcije. Poželjno je odvojiti ove funkcionalnosti u razdvojene kontejnere.
- Pristup periferijama – poželjno je da se funcionalnosti koje pristupaju istim periferijama, ili grupi periferija, odvoje u zasebne kontejnere, kako bi delovi sistema koji pristupaju periferijama bili međusobno izolovani.
- Privilegije – ukoliko neke funkcionalnosti zahtevaju korišćenje operacija sa administrativnim pravima, poželjno je odvojiti ih u zaseban kontejner, i time obezbediti da budu izolovane od ostatka sistema.
- Mrežna komunikacija – funkcionalnosti koje koriste pouzdanu komunikaciju treba da se izoluju od onih koje koriste nepouzdanu komunikaciju.

Ne postoji jedinstven način razdvajanja funkcionalnosti, ali svakako treba voditi računa da se što više poštuju gore navedeni predlozi. Ukoliko određeni kontejner ima veća prava pristupa, to se javlja veća potreba da se taj kontejner zaštiti i izoluje. Delovi koda koji imaju manje prava poželjno je izdvojiti u zasebne kontejnere, kako bi se u slučaju neovlašćenog pristupa tom delu koda obezbedilo da se ne može uticati na druge delove koda, za koje je potrebno imati veća prava pristupa, i time ugrozila zaštita podataka koji moraju ostati zaštićeni.

Na osnovu navedenih preporuka i razmatranja, na STB-u se funkcionalnosti mogu izolovati u zasebne kontejnere, na sledeći način:

- STB UI – Kontejner koji izoluje browser za renderovanje main STB UI. Browser menager je odgovoran za upravljanje ulaznim parametrima RC (remote controler) dobijenim iz DirectFB (Direct frame buffer), koje zatim prosleđuje HBBTV-u, glavnom korisničkom intefejsu ili drugim kontejnerima, ukoliko ima potrebe za tim. Takođe treba da poseduje LIRC deamon koji se koristi za dekodovanje IR poruka prosleđenih ili pristiglih iz drajvera.
- MEDIA - Unutar ovog kontejnera se nalaze procesi koji su zaduženi za skladištenje Audio/Video podataka, komunikacije sa eksternim serverom, pristup spoljnoj memoriji prilikom procesa snimanja sadržaja...
- SECURE - Unutar secure kontejnera se nalaze osetljivi podaci, potrebni za dekodovanje i deskremblovanje, kojima je potrebna najveća zaštita (security biblioteke, sertifikati, licence...)
- USBMNG - Unutar ovog kontejnera nalazi se proces koji upravlja USB spoljnom memorijom. Ovaj proces je zadužen, između ostalog, za pokretanje i formatiranje USB uređaja (samo osnovne operacije, ne upravlja upisom ili čitanjem medija podataka). Ovaj kontejner mora imati obezbeđena administrativna prava pristupa.
- CONNECT - Unutar ovog kontejnera se nalazi proces koji je zadužen za upravljanje internet komunikacijom.



Sl. 4. Podela STB funkcionalnosti u izolovane LXC kontejnere

Na slici 4 se može videti grafički prikaz podele funkcionalnosti u LXC kontejnere.
Primena linux kontejnera, ili neke metode izolacije sistema, često je obavezan mehanizam, koji linux STB mora da poseduje, kako bi mogao uspesno biti ugrađen neki sistem zaštite u STB.

VI. Uticaj korišćenja LXC-a na performanse sistema

Kako bi se sagledao uticaj korišćenja LXC-a na performanse sistema, obavljena su određena merenja, čiji su rezultati zatim upoređeni sa rezultatima dobijenim korišćenjem sistema koji ne koristi mehanizam LXC-a. U cilju evaluacije korišćenjen je isti STB uređaj i u oba slučaja je bila startovana aplikacija i svi programi učitani u memoriju.

U tabeli 1 su prikazani rezultati merenja broja izvršenih operacija sa celim brojevim i operacija sa brojevima sa pokretnim zarezom, tokom vremena od 1 s, sa brojem ponavljanja 10000000. Prikazane su prosečne vrednosti.

Tabela 1

Prosečan broj izvršenih operacija tokom 1s

	Sa LXC	Bez LXC
Broj operacija sa celim brojevima	4739336.5	4672897.0
Broj operacija sa brojevima sa pokretnim zarezom	1180.55	1179.21

U tabeli 2 i 3 su redom prikazani i upoređeni rezultati merenja brzine upisa i čitanja celobrojnih podataka u RAM memoriju.

Tabela 2

Brzina upisa celobrojnih podataka u RAM memoriju

	Sa LXC	Bez LXC
1 Kb blok	5393.89 MB/s	5470.93 MB/s
4 Kb blok	5833.71 MB/s	6667.90 MB/s
16 Kb blok	6704.24 MB/s	6474.12 MB/s
64 Kb blok	6650.04 MB/s	5793.39 MB/s
256 Kb blok	4529.99 MB/s	4271.54 MB/s
1024 Kb blok	1258.92 MB/s	1800.65 MB/s
4096 Kb blok	1167.96 MB/s	1079.12 MB/s
16384 Kb blok	1083.21 MB/s	967.47 MB/s

Tabela 2

Brzina čitanja celobrojnih podataka iz RAM memorije

	Sa LXC	Bez LXC
1 Kb blok	5982.03 MB/s	5930.57 MB/s
4 Kb blok	6629.49 MB/s	6631.23 MB/s
16 Kb blok	6639.82 MB/s	5960.21 MB/s
64 Kb blok	3327.35 MB/s	2979.99 MB/s
256 Kb blok	2931.33 MB/s	2949.76 MB/s
1024 Kb blok	1333.88 MB/s	1204.70 MB/s
4096 Kb blok	1517.67 MB/s	1468.60 MB/s
16384 Kb blok	1501.93 MB/s	1521.87 MB/s

U tabeli 4 upoređena su vremena pokretanja sistema sa i bez korišćenja LXC-a. Vreme pokretanja, u ovom slučaju, podrazumeva period od trenutka pokretanja sistema, do trenutka kada su svi programi ucitani u memoriju i aplikacija pokrenuta.

Tabela 4

Prosečno vreme pokretanja sistema

	Sa LXC	Bez LXC
Vreme pokretanja sistema	101 s	101 s

Na osnovu prikazanih rezultata zaključeno je da korišćenje LXC-a značajno ne utiče na performance sistema, uz postignut viši nivo zaštite STB uređaja, korišćenjem LXC-a.

VII. Zaključak

Na osnovu praktične realizacije gore opisanih metoda zaštite, uspešno je postignut viši nivo zaštite STB uređaja, korišćenjem LXC paketa. Ispoštovane su navedene preporuke prilikom grupisanja funkcionalnosti, i postignuta je bolja zaštita bez značajnog uticaja na performanse sistema. Korišćenjem LXC-a kreiran je potreban nivo sigurnosti okruženja, kako bi uspešno mogao biti integrisan bilo koji CAS. STB uređaji, koji se zasnivaju na LXC izolaciji procesa, su uspešno praktično realizovani, i već se nalaze u komercijalnoj upotrebi, donoseći brojne pogodnosti, kako operaterima, tako i korisnicima. Zbog povećanog nivoa zaštite, predstavljaju najsavremeniji i najsigurniji uređaj za prijem i obradu digitalnog televizijskog signala.

Zahvalnica

Hvala kolegama Mlikota Borisu, Radonjić Mariu i Bako Miroslavu na njihovoj stručnoj pomoći, znanju i kolegijalnosti, bez koje ovaj rad ne bi bio uspešno realizovan.

Abstract

This paper presents implementation of security protection system on Linux Set Top Box (STB) devices. Goal of this paper is to represents how to achieve a higher level of protection on STB devices, using Linux container methods, and how critical processes and data can be isolated from unauthorized access. In this paper was given a short overview of Linux container methods and suggested one solution for using this methods on STB device. It is shown how using of this methods have an effect on system performances.

One solution of data protection in Linux Set Top Box

Daljinska obrada mamografskih slika korišćenjem Matlab Web Servisa

Marina Milošević, Dejan Vujičić, Željko Jovanović, Đorđe Damnjanović i Maja Radović

***Apstrakt*— U ovom radu predložena je metoda za daljinsku obradu mamografskih slika (mamograma) bazirana na primeni Matlab Web Servisa. Kreiran je udaljeni sistem za obradu slike u vidu Matlab aplikacije koja se izvršava na serveru. Grafički korisnički interfejs omogućava korisniku da učita mamografsku sliku koja se šalje na server, unese ulazne parametre neophodne za obradu slike i nakon obrade prikaže dobijene rezultate. Predstavljeni računarski sistem za obradu mamografskih slika baziran je na primeni metoda za segmentaciju mamograma kojima je moguće povećati vidljivost najranijih pokazatelja tumora - mikrokalcifikacija. Vidljivost mikrokalcifikacija značajno je poboljšana primenom Sobelove metode za izdvajanje ivica i metode za povećavanje kontrasta slike.**

***Ključne reči*—Mamografija; Mikrokalcifikacije; Segmentacija slike; Matlab; Web servis.**

I. Uvod

Kancer dojke je najčešći oblik maligniteta kod žena, koji karakteriše neprekidan porast obolelih [1]. Dijagnostička metoda koja omogućava precizno otkrivanje promena na tkivu dojke u najranijem stadijumu razvoja je mamografija [2,3].

Mikrokalcifikacije su veoma važan i ponekad jedini znak prisutnosti kancera dojke u početnom stadijumu razvoja, zbog čega je detektovanje mikrokalcifikacija veoma važan deo dijagnoze. U pitanju su mala ležišta kalcijuma u tkivu dojke, koja su na mamografskom snimku (mamogramu) vidljiva kao vrlo mali objekti visokog intenziteta u odnosu na okolno tkivo [4]. Prisutnost šuma na slici, nehomogena pozadina mikrokalcifikacija na mamogramu, kao i pojava svetlijeg tkiva dojke u odnosu na mikrokalcifikacije, u velikoj meri otežavaju njihovo detektovanje i mogu dovesti do toga da radiolog previdi postojeće mikrokalcifikacije. Iz tog razloga, razvoj CAD (engl. *Computer Aided Detection - CAD*) algoritama koji omogućavaju upotrebu računara u cilju potvrđivanja mišljenja radiologa ili u cilju donošenja uporedne dijagnoze kada nije moguće konsultovati drugog radiologa, je od neprocenjivog značaja. U osnovi CAD sistema opisanog u ovom radu stoji metoda za izdvajanje ivica primenom Sobelovog operatora i metoda za povećavanje kontrasta mamograma.

Značaj realizovanog CAD sistema za donošenje uporedne dijagnoze se povećava ukoliko je on dostupan većem broju korisnika u bilo kojem trenutku. Primenom Matlab web servisa omogućen je pristup opisanom CAD sistemu za detekciju mikrokalcifikacija na mamogramu sa udaljenih lokacija u svakom trenutku.

Matlab web servis ima ulogu da omogući klijentima (korisnicima) da sa udaljenih lokacija posredstvom internet pregledača pristupaju Matlab aplikacijama, koji se nalaze na serverskom računaru.

Opisani CAD sistem za detekciju mikrokalcifikacija na mamogramu napisan je u Matlabu i smešten je na lokalnom računaru koji obavlja ulogu servera. Posredstvom internet pregledača korisnik učitava mamografsku sliku i unosi potrebne vrednosti koje se šalju na server kao ulazni parametri CAD sistema za detekciju mikrokalcifikacija. Nakon izvršavanja Matlab programa na serverskom računaru, rezultat obrade unešenih podataka, tj. segmentirani mamogram postaje dostupan korisniku putem internet pregledača.

II. Primenjene metode

A. *Detektovanje mikrokalcifikacija na mamogramu*

Pre same analize mamograma sprovedena je predobrada snimaka koja obuhvata eliminisanje šuma i izdvajanje područja od interesa, kako bi se obezbedili optimalni uslovi za dalju obradu. U cilju povećanja vidljivosti mikrokalcifikacija, na mamograme su primenjene dve segmentacione metode: metoda za izdvajanje ivica primenom Sobelovog operatora i metoda za povećavanje kontrasta.

1) *Predobrada mamografskih snimaka*

Predobrada mamograma ima za cilj da obezbedi bolje uslove za izdvajanje željenih objekata. Faza predobrade predstavljenog CAD sistema sastoji se od dva segmenta: uklanjanja šuma sa slike i izdvajanja područja od interesa.

Efikasno uklanjanje šuma sa slike bez narušavanja kvaliteta obrađene slike dovodi do poboljšanja rezultata kasnije obrade.

Dejan Vujičić – Fakultet tehničkih nauka Univerziteta u Kragujevcu, Svetog Save 65, 32000 Čačak, Srbija (e-mail: dejan.vujicic@ftn.kg.ac.rs).

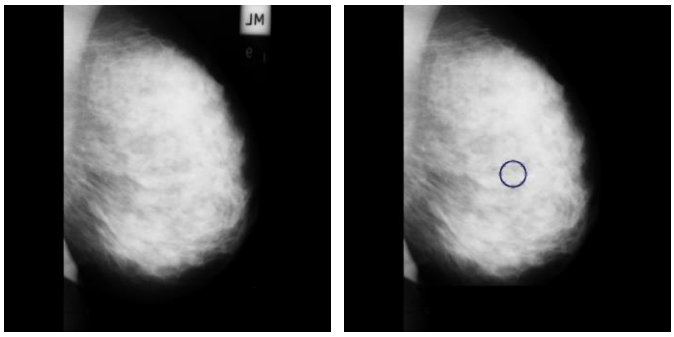
Željko Jovanović – Fakultet tehničkih nauka Univerziteta u Kragujevcu, Svetog Save 65, 32000 Čačak, Srbija (e-mail: zeljko.jovanovic@ftn.kg.ac.rs).

Đorđe Damnjanović– Fakultet tehničkih nauka Univerziteta u Kragujevcu, Svetog Save 65, 32000 Čačak, Srbija (e-mail: djordje.damnjanovic@ftn.kg.ac.rs).

Maja Radović – Fakultet tehničkih nauka Univerziteta u Kragujevcu, Svetog Save 65, 32000 Čačak, Srbija (e-mail: maja.radovic@ftn.kg.ac.rs).

Uklanjanje šuma sa mamograma izvršeno je primenom medijan filtra [5].

Izdvajanje područja od interesa koje podrazumeva dojku izdvojenu iz pozadine, je neophodan segment faze predobrade, posebno u slučaju skeniranih analognih mamograma koji imaju problem nejednako osvetljene pozadine i često sadrže nepoželjne objekte koje je potrebno ukloniti. Za izdvajanje područja od interesa primenjena je procedura predstavljena u [6]. Rezultat primene ove procedure na mamogram iz Mini-MIAS baze podataka [7] sa kojeg je uklonjen šum (Sl. 1(a)), prikazan je na Sl. 1 (b). Na Sl. 1 (b) zaokruženo je područje na kojem su prisutne mikrokalcifikacije.



(a) (b)

Sl. 1. Predobrada mamograma: a) Mamogram mdb266 iz Mini-MIAS baze podataka sa kojeg je uklonjen šum, b) Dojka izdvojena iz pozadine sa zaokruženim klasterom mikrokalcifikacija.

2) Segmentacija mamografskih snimaka

U cilju povećanja verovatnoće otkrivanja klastera mikrokalcifikacija i pojedinačnih mikrokalcifikacija, primenjena procedura za segmentiranje mamograma obuhvata dve faze.

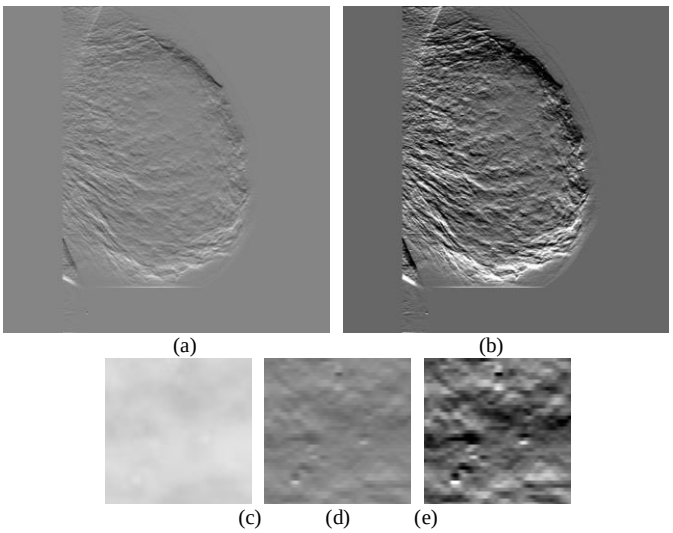
Prva faza segmentacije mamograma podrazumeva proces kojim se slika deli na dva dela, pozadinu i ivice mikrokalcifikacija. Ivice mikrokalcifikacija izdvojene su primenom Sobelovog operatora [8]. Sobelov detektor ivica je najpoznatiji i najpopularniji među klasičnim metodama za detekciju ivica zbog svoje jednostavne implementacije i dobrih performansi. Rezultat primene ove metode je dvodimenzionalna mapa gradijenata izračunatih u svakoj tački slike, pri čemu je amplituda gradijenta velika na ivicama objekata, dok je unutar i izvan objekata uglavnom niska [9]. Dvodimenzionalna mapa y-gradijenata (projekcija gradijenta slike na y-osu), dobijenih primenom Sobelovog operatora, prikazana je na Sl. 2 (a). Na ovoj slici, vidljivost mikrokalcifikacija je malo bolja u poređenju sa originalnim mamogramom.

U drugoj fazi segmentacije mamograma, na sliku dobijenu primenom Sobelovog operatora primenjena je operacija povećavanja kontrasta. Povećavanje kontrasta, kojim se postiže bolja vidljivost objekata na slici, ostvareno je primenom operacije za podešavanje vrednosti intenziteta piksela slike. Transformacija intenziteta piksela izvršena je preslikavanjem vrednosti ulazne slike u nove vrednosti na izlaznoj slici tako što se vrednosti intenziteta piksela koje se nalaze između zadatih graničnih vrednosti u ulaznoj slici (*low_in*, *high_in*) preslikaju u vrednosti između zadatih graničnih vrednosti u izlaznoj slici (*low_out*, *high_out*). Sve vrednosti manje od *low_in* se preslikavaju u vrednost *low_out*, a vrednosti veće od *high_in* se preslikavaju u vrednost *high_out*.

Primena opisane procedure za povećavanje kontrasta rezultirala je značajnim poboljšanjem vidljivosti mikrokalcifikacija (Sl. 2 (b)). Mikrokalcifikacije su postale lako uočljive, jasno se vidi gde se nalaze i kakvog su oblika, što je veoma bitno zbog njihove klasifikacije na maligne i benigne.

Na kraju, lokalizacija klastera i pojedinačnih mikrokalcifikacija može se izvršiti upoređivanjem segmentiranih i originalnih mamograma.

Sl. 2 (c) prikazuje klaster mikrokalcifikacija izdvojen iz originalnog mamograma. Rezultati prve i druge faze segmentacije primenjene na izdvojene delove mamograma prikazani su na Sl. 2 (d) i Sl. 2 (e), respektivno.



(a) (b)

(c) (d) (e)

Sl. 2. Segmentacija mikrokalcifikacija: (a) Dvodimenzionalna mapa y-gradijenata dobijenih primenom Sobelovog operatora, (b) Rezultat primene operacije povećavanja kontrasta, (c) Klaster mikrokalcifikacija izdvojen iz originalnog mamograma, (d) Rezultat prve faze segmentacije izdvojenih mikrokalcifikacija, (e) Rezultat druge faze segmentacije izdvojenih mikrokalcifikacija.

Vizuelnom procenom utvrđeno je da primenjena metoda segmentacije daje zadovoljavajuće rezultate kod detektovanja mikrokalcifikacija. Efikasnost ove metode potvrđena je klasifikacijom originalnih i segmentiranih mamograma u dve kategorije, kategoriju mamograma koji sadrže mikrokalcifikacije i kategoriju mamograma koji ih ne sadrže, primenom klasifikacione metode opisane u [6].

Mini-MIAS baza podataka sadrži 23 mamograma na kojima su prisutne mikrokalcifikacije, pri čemu je sa tih mamograma moguće izdvojiti 28 klastera mikrokalcifikacija. U klasifikacionom testu korišćeno je ukupno 60 uzoraka i to 28 slika koje sadrže klastere mikrokalcifikacija i 32 slike koje predstavljaju delove mamograma na kojima nema mikrokalcifikacija. U tri klasifikaciona testa primenjene su tri različite klasifikacione šeme: klasifikator zasnovan na podržavajućim vektorima (engl. Support Vector Machine - SVM) [10], klasifikator koji koristi metodu k-najbližih suseda (engl. K-Nearest Neighbor - k-NN) [11] i naivni Bajesov klasifikator [12].

Rezultati predstavljeni u [13] pokazali su da je u sva tri klasifikaciona testa najuspešnija bila klasifikacija segmentiranih delova mamograma sa povećanim kontrastom. Zatim sledi klasifikacija segmentiranih delova bez povećanja kontrasta, dok je najmanje uspešna klasifikacija delova originalnih mamograma. Deo pomenutih rezultata prikazan je u Tabeli 1.

Tačnost klasifikacije nešto veća od 50%, čini klasifikaciju delova originalnih mamograma neuspešnom jer je 50% ispravno prepoznatih uzoraka jednako slučajnom pogađanju. Nešto veća tačnost klasifikacije postignuta je klasifikovanjem delova mamograma segmentiranih primenom Sobelovog operatora. Tačnost klasifikacije ostvarena testiranjem segmentiranih uzoraka sa povećanim kontrastom, opravdava primenu predložene metode za detektovanje mikrokalcifikacija.

TABELA I
TAČNOST KLASIFIKACIJE ORIGINALNIH I SEGMENTIRANIH MAMOGRAMA OSTVARENA PRIMENOM SVM KLASIFIKATORA, K-NN KLASIFIKATORA I NAIVNOG BAJESOVOG KLASIFIKATORA.

	Tačnost klasifikacije	
SVM klasifikator	Originalni mamogrami	56.7 %
	Sobel-segmentirani	65 %
	Nakon povećanja kontrasta	88.3 %
K-NN klasifikator	Originalni mamogrami	58.3 %
	Sobel-segmentirani	60 %
	Nakon povećanja kontrasta	73.3 %
Naivni Bajesov klasifikator	Originalni mamogrami	53.3 %
	Sobel-segmentirani	65 %
	Nakon povećanja kontrasta	78.3 %

Na osnovu rezultata prikazanih u Tabeli 1, koji su detaljno izloženi i analizirani u [13], može se zaključiti da je svaka faza segmentacije mamograma doprinela poboljšanju vidljivosti mikrokalcifikacija.

B. Matlab web servis

Internet je danas najefikasniji način za komunikaciju i razmenu informacija. Takođe, omogućava korisnicima obradu podataka pomoću web baziranih aplikacija, pri tom nezahtevajući dodatni softver za pokretanje tih aplikacija. Matlab web servis (MWS) je programski dodatak MATLAB programskom paketu koji omogućava korisnicima da pristupaju aplikacijama napisanim u ovom programu preko interneta koristeći standardne web tehnologije. MWS nije deo standardne Matlab instalacije, već se instalira kao poseban dodatak. U ovom radu korišćen je programski dodatak Modelit Matlab Webservice Toolbox [14].

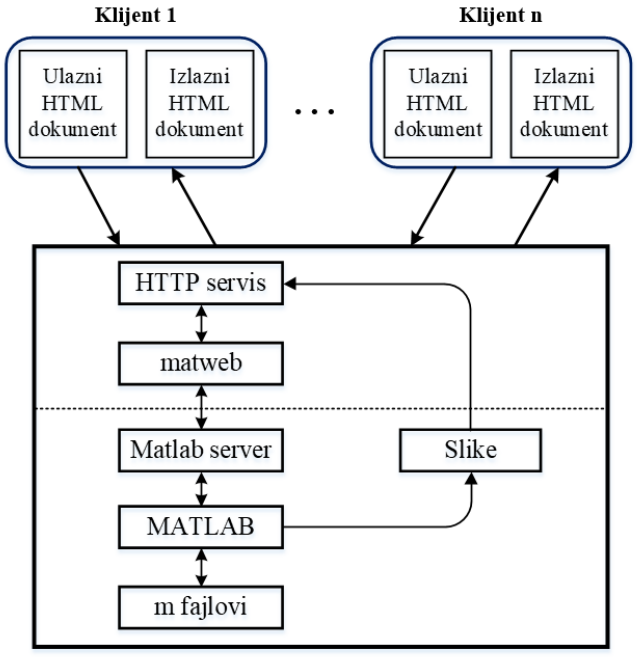
Najjednostavnija konfiguracija MWS podrazumeva da korisnik sa klijentskog računara, pomoću internet pregledača zadaje vrednosti ulaznih parametara i pristupa aplikacijama napisanim u Matlab-u, koje se nalaze na serverskom računaru. Nakon izvršavanja Matlab programa na serveru, dobijeni rezultati se prosleđuju korisniku preko internet pregledača. Na ovaj način, korisnici mogu da pristupaju aplikacijama napisanim u Matlab-u preko interneta sa bilo koje udaljene lokacije na jednostavan način, bez dodatnih troškova i potrebe da instaliraju ovaj programski paket.

MWS aplikacija predstavlja kombinaciju Matlab izvršnih datoteka (m fajlova), HTML (HyperText Markup Language) i grafičkih fajlova. Realizacija MWS aplikacije se može podeliti na sledeće korake:

- Kreiranje korisničkog interfejsa u vidu HTML dokumenta (web strane) za unos ulaznih podataka od strane klijenta i za prikaz rezultata dobijenih nakon izvršavanja Matlab programa,
- Pisanje Matlab programa u vidu izvršnog m fajla koji:
  - preuzima podatke koje je klijent uneo u ulaznom HTML dokumentu,
  - obrađuje unete podatke i generiše zahtevane izlazne podatke (numeričke vrednosti, tekst, slike, itd.),
  - Prosleđuje dobijene rezultate u izlazni HTML dokument.
- Navođenje naziva glavnog izvršnog m fajla i pripadajućih konfiguracionih podataka u konfiguracionom fajlu.

Na Sl. 3 prikazan je blok dijagram koji opisuje komunikaciju između klijentske aplikacije (klijenta) i Matlab-a preko interneta. Klijentska aplikacija (najčešće je to internet pregledač) otvara web stranu na kojoj je omogućen unos vrednosti ulaznih parametara, kako numeričkih, tako i grafičkih (slike).

Nakon unosa potrebnih ulaznih vrednosti od strane klijenta u ulaznom HTML dokumentu, klijentski zahtev se prosleđuje *matweb* komponenti preko HTTP servisa. Komponenta dijagrama *matweb* je TCP/IP (Transmission Control Protocol / Internet Protocol) klijent koji komunicira sa Matlab serverom. Njegova uloga je da korišćenjem HTTP servisa (Common Gateway Interface - CGI) preuzme podatke unete na web strani i da ih prosledi Matlab serveru.



Sl. 3. Komunikacija između klijentske aplikacije i Matlab-a preko interneta.

Matlab server predstavlja višenitni TCP/IP server koji upravlja komunikacijom između klijentske aplikacije i Matlab-a. Konfigurisan je tako da osluškuje zahteve na TCP/IP portovima koji su definisani u *matlabserver.conf* datoteci. Matlab server učitava traženi m fajl u Matlab i po završetku njegovog izvršavanja prosleđuje dobijene izlazne podatke *matweb* komponenti. Nakon toga, *matweb* ih posredstvom HTTP servisa predaje klijentu u izlaznom HTML dokumentu.

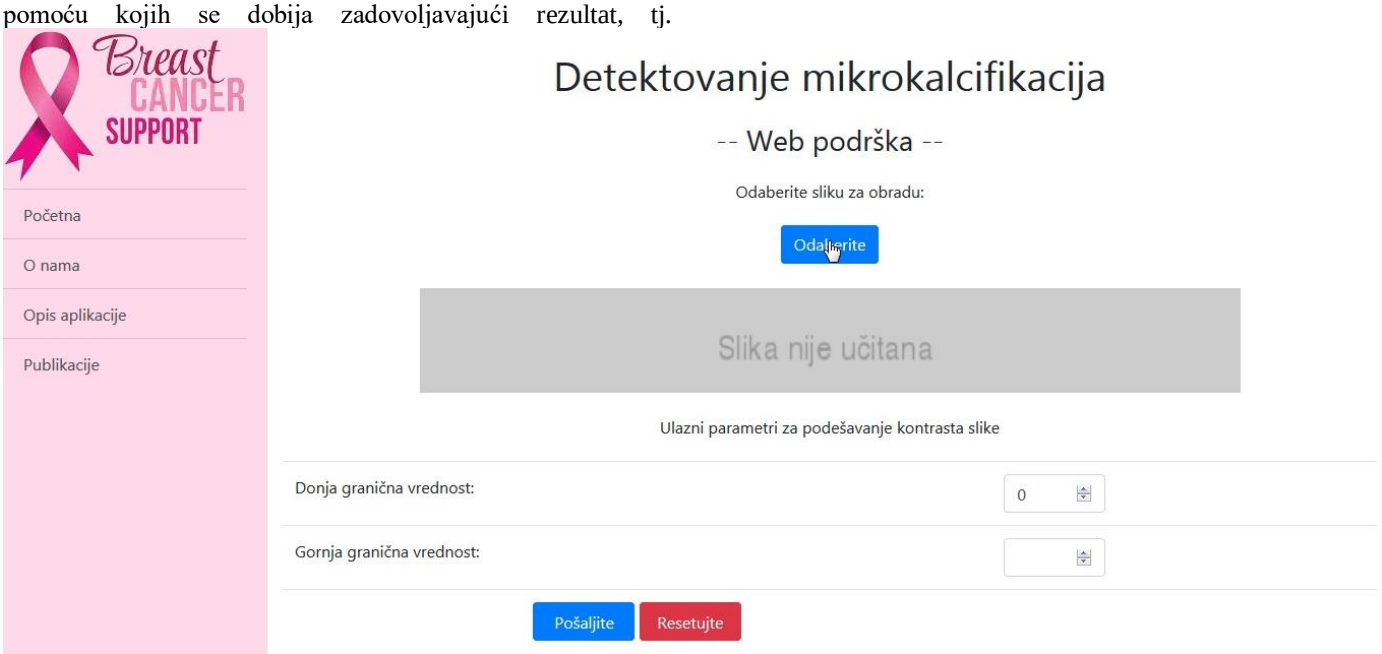
III. Rezultati

Korisnički interfejs MWS aplikacije sastoji se od dva osnovna HTML dokumenta, jednog za učitavanje mamograma koji se obrađuje i unos vrednosti ulaznih parametara i drugog za prikaz rezultata dobijenih nakon izvršavanja Matlab koda, kao i nekoliko pomoćnih HTML dokumenata čija je uloga da korisnicima olakšaju rad sa aplikacijom. Aplikaciju može da koristi svaki korisnik interneta, na svom računaru sa odgovarajućim internet pregledačem. MWS aplikacija testirana je pomoću Mozilla Firefox pregledača korišćenjem lokalnog računara koji je obavljao ulogu servera.

Korisnički interfejs za učitavanje mamograma i unos vrednosti ulaznih parametara prikazan je na Sl. 4. Klikom na dugme "*Odaberite*" korisnik bira mamogram koji će se obrađivati. Nakon učitavanja željenog mamograma i njegovog prikaza koji potvrđuje da je mamogram ispravno učitan, potrebno je zadati donju i gornju graničnu vrednost za podešavanje kontrasta slike dobijene primenom Sobelovog operatora. Polja predviđena za zadavanje graničnih vrednosti omogućavaju korisniku da izabere jednu od ponuđenih vrednosti iz dozvoljenog opsega (opseg vrednosti od 0 do 1, sa korakom 0,1). Korisnik može da zadaje različite vrednosti ulaznih parametara sve dok ne pronađe optimalne vrednosti pomoću kojih se dobija zadovoljavajući rezultat, tj. mamogram na kojem se jasno vidi da li su mikrokalcifikacije prisutne. Klikom na dugme "*Pošaljite*" učitana slika i unete vrednosti se prosleđuju aplikaciji na obradu. Dugme "*Resetujte*" omogućava brisanje svih zadatih vrednosti, uključujući i odabrani mamogram.

Nakon obrade unešenih podataka, otvara se nova web strana na kojoj se prikazuju originalni mamogram i mamogram dobijen nakon primene Sobelovog operatora i operacije za povećavanje kontrasta slike (Sl. 5). Vizuelnim upoređivanjem segmentiranog i originalnog mamograma moguće je utvrditi lokacije na kojima su prisutne mikrokalcifikacije ili zaključiti da mikrokalcifikacije nisu prisutne na datom mamogramu. Klikom na dugme "*Sačuvajte*" korisnicima aplikacije je data mogućnost čuvanja obrađenog mamograma na sopstvenom računaru, radi dalje analize i obrade.

Na levoj strani HTML dokumenata prikazanim na Sl. 4 i Sl. 5 nalaze se linkovi sa informacijama koje korisnicima olakšavaju primenu aplikacije, posebno prilikom prvog susreta sa aplikacijom. Na linku *O nama* date su osnovne informacije o autorima aplikacije. Kratak opis Matlab aplikacije za detektovanje mikrokalcifikacija dat je na web strani na koju ukazuje link *Opis aplikacije*. Ovde su prikazane informacije o mikrokalcifikacijama, predobradi mamograma, Sobelovom detektoru ivica i povećavanju kontrasta mamograma. Prilikom prvog pristupa aplikaciji neophodno je da korisnik pročita ovaj informativni tekst, kako bi mogao da zada ispravne vrednosti ulaznih parametara. Izborom linka *Publikacije* otvara se web strana na kojoj je dat spisak publikovanih naučnih radova autora aplikacije, čija je tema detektovanje mikrokalcifikacija.



Sl. 4. Web strana za učitavanje mamograma i unos vrednosti ulaznih parametara.

Sl. 5. Web strana za prikaz rezultata obrade mamograma.

IV. Zaključak

U radu je predstavljen sistem za obradu mamograma koji je zahvaljujući primeni Matlab Web Servisa dostupan preko interneta. Korisnički interfejs čine web stane za unos podataka i prikaz rezultata. Prema tome, korisnicima nije potreban dodatni softver, pored internet pregledača, da bi koristili ovu web baziranu aplikaciju.

Korisnici MWS aplikacije za otkrivanje mikrokalcifikacija na mamogramu mogu da učitaju sopstveni mamogram i da unose različite vrednosti ulaznih parametara sve dok ne dobiju zadovoljavajući rezultat, tj. mamogram na kojem se jasno vidi da li su mikrokalcifikacije prisutne.

Najvažnija prednost primene MWS-a je što korisnici mogu koristiti aplikacije napisane u Matlab-u bez instaliranja Matlab softvera, čija je cena licence poprilično visoka. Korisnici takođe ne moraju da imaju neko posebno znanje o ovom programskom paketu i o programiranju u njemu da bi pokrenuli aplikacije. Za izvršavanje MWS aplikacije dovoljno je imati odgovarajući web pregledač i biti upoznat sa namenom Matlab aplikacije, kako bi se na ispravan način zadale vrednosti ulaznih parametara aplikacije.

MWS aplikacije su dostupne preko standardnog HTTP protokola. Ovo omogućava povezivanje sa Matlabom, ne samo preko internet pregledača, već preko bilo koje aplikacije koja implementira ovaj protokol, kao što su na primer Java apleti.

Prednosti same Matlab aplikacije su velika tačnost detektovanja mikrokalcifikacija čak i kod mamograma sa vrlo gustim tkivom dojke i veoma kratko vreme obrade mamograma.

Pored brojnih prednosti, MWS ima i neke nedostatke. Jedan od nedostataka je fiksna struktura aplikacija napisanih u Matlab-u. U nekim slučajevima, promena strukture aplikacije bi bila korisna. Dalji rad biće usmeren ka nadograđivanju opisane aplikacije za otkrivanje mikrokalcifikacija, koje se ogleda u pružanju mogućnosti izbora jednog od nekoliko ponuđenih detektora ivica.

ABSTRACT

In this paper, we propose a method for remote processing of mammographic images (mammograms) based on Matlab Web Service. We created a remote image processing system in the form of a Matlab application running on the server. The graphical user interface allows the user to upload the mammographic image that is sent to the server, enter the input parameters necessary for image processing and shows results obtained after processing. The presented computer system for mammograms processing is based on mammograms segmentation methods which can increase the visibility of the earliest tumor indicators - microcalcifications. The visibility of microcalcifications is significantly improved using the Sobel edge detection method and image contrast enhancement method.

Remote processing of mammographic images using Matlab Web Service

How to Build Internet Exchange Point from scratch

Nenad Krajnović, *Senior Member, IEEE*

***Abstract*—This Internet Exchange Points (IXPs) play a major role at the core of the Internet peering ecosystem. Because of that, IXPs functioning is of crucial importance for the Internet economy. IXPs should provide high availability in operation, high throughput and minimal latency. Typical IXP is built on layer 2 Ethernet switches. Using Ethernet switches has many challenges, such as how to implement redundant links in the network topology without using Spanning-tree protocol, or how to protect the network from broadcast storm, or how to prevent traffic leaking from IXP members. Choice of datacenters to be present in, and their number and connection topology should be coupled not only with technological, but also financial issues, yet with network neutrality approach always coming first. Besides Ethernet drawbacks, additional problem is how to achieve proper propagation of all routing prefixes toward IXP members. For solving this issue, all IXPs are using route-servers for simplification of route prefixes announcements among IXP members. And route-servers are based on using open-source software, such as BIRD, Quagga or OpenBGPD, with all pros and cons of using open-source software. Since the Internet stability is of major importance, operator of an IXP is responsible for controlling route prefixes announcement of every IXP member. This is related with Internet Routing Registries which should have updated information about route prefixes that every Autonomous System (AS) is announcing. Unfortunately, IRR databases are not completely accurate which means the operator of IXP should find the approach to filter announcement in proper way. All those issues should be overcome to end up with fully functional IXP which is important milestone in Internet architecture. Besides global Internet, IXPs are also of major importance for every country. IXP provides that all local content stay local instead to go around the globe in case of IXP missing, which significantly reduce the expenses for ISPs, lower latency, improve stability, and introduce scalable capacity. This is very important taking into account the importance of Internet for economy of every modern country. This paper presents experience and best practice implemented in building an Internet Exchange Point in the case of Serbian Open Exchange.**

***Index Terms*— Internet; IXP; BIRD; evolution of IXP.**

I. Introduction

IXPs became critical infrastructure for every country and their functioning is of crucial importance for the Internet economy. In this article it will be covered main technical, operational, and technological aspects, but will reflect on equally important issues of building IXP community, building trust in superb operational performance, and sharing know-how, and best practices around the technological platform. IXPs should provide high availability in operation, high throughput and minimal latency. Typical IXP is built on layer 2 Ethernet switches. Choice of datacenters to be present in, and their number and connection topology should be coupled not only with technological, but also financial issues, yet with network neutrality approach always coming first. Additional problem is how to achieve proper propagation of all IP prefixes toward IXP members. For solving this issue, vast majority of IXPs are using route-servers for simplification of IP prefixes announcements among IXP members. Route-servers are very often based on open-source software, such as BIRD, Quagga or OpenBGPd [1], with all pros and cons of using open-source software. Since the Internet stability is of major importance, operator of an IXP is responsible for controlling IP prefixes announcement of every IXP member. This is related with Internet Routing Registries (IRR) which should have updated information about IP prefixes that every Autonomous System (AS) is announcing. Unfortunately, IRR databases are not always completely accurate, due to fast changes in ISP business, and lack of time, and genuine interest of ISPs to keep the IRR database fully up-to-date, which means the operator of IXP should find the approach to filter announcement in proper way. In addition to that, there is global initiative to improve Internet routing stability named MANRS (Mutually Agreed Norms for Routing Security) [2].

Importance of open communication, sharing of best practices, and protecting other market players from security challenges coming from your own network, could not be stressed enough. Building superb technological platform without having a proper set of rules of engagement is dead end. All those issues should be overcome to end up with fully functional IXP which is important milestone in overall Internet architecture. Besides other advantages, IXP provides that all local content stay local instead to traverse around the globe in case of IXP missing, which significantly reduce the expenses for ISPs, keep the latency low, improve stability, and introduce scalable capacity. IXPs are also important milestone in national Internet infrastructure security. Operating IXP inside the country, ISPs can count on stable work even in case of huge DDoS (Distributed Denial of Service) attack which can come from the Internet. This article presents experience and best practice implemented in building an Internet Exchange Point in the case of Serbian Open Exchange - SOX [3].

Nenad Krajnović is with SOX – Serbian Open Exchange, 78 Todora Dukina, 11000 Belgrade, Serbia (e-mail: krajko@sox.rs).

II. Layer 2 IXP Realization

Today, IXPs are based on Layer 2 Ethernet technology. Ethernet technology offers very good scalability of access link capacity (starting from gigabit Ethernet, over 10G Ethernet to 100G and 400G Ethernet with link aggregation possibility) and the network itself (it is easy task to add one additional Ethernet switch in the network). With Ethernet switches, it is very easy to establish point-to-point connection between users by using virtual LAN (VLAN) and QinQ functions, if it is necessary. Because of this service, support of jumbo Ethernet frames is a must. Since IXP can be treated as telecommunication services exchange, this possibility is very important. At SOX, besides common Internet Exchange services, service of point-to-point virtual links based on VLAN technology are offered.

Ethernet has some functionality that could cause problems in everyday operation of an IXP. One of the most dangerous is broadcast storm. To protect the network, switches must have possibility to rate-limit broadcast traffic. The limit for broadcast traffic should be very small, since in standard working conditions it almost does not exist as a regular traffic. The same goes for unsolicited multicast traffic, in the event it exists in the network. It is important to remember that IPv6 is using multicast instead of broadcast. So, if IXP support IPv6 protocol, multicast traffic will be present. Some IXP members utilize Private VLANs to exchange multicast streams between networks, such as TV channels, and in that case multicast per specific VLAN should be fully enabled. Traffic filtering on Layer 2 level is also very important. It is not unusual situation that IXP customers physical link from IXP terminate on Ethernet switch and forward traffic via VLAN to the router. In such situation, it is very possible, almost imminent, that IXP customer would either send or receive some unsolicited traffic such as BPDU (Bridge Protocol Data Unit) frames from Spanning Tree Protocol, CDP (Cisco Discovery Protocol) frames, LLDP (Link Layer Discovery Protocol) frames, etc. Forwarding of such frames can cause blocking of interfaces on IXP's customers equipment. To prevent this predicament, incoming traffic should be filtered by MAC addresses and ethertype field in packet. Only 3 ethertypes should be accepted: IPv4 (0x0800), ARP (0x0806) and IPv6 (0x86dd). If the Ethernet port on IXP's switch is in access mode than "one MAC per port" feature should be used. Only frames with acceptable source and destination MAC addresses should be accepted and all other traffic should be blocked. In case the port is in trunk mode, traffic filtering should be reduced because in some VLANs can exists regular STP, CDP, LLDP frames. For those situations, per VLAN Layer 2 filtering feature would be preferable. One additional measure to put under control broadcast traffic is to establish *honey-pot* server for all IPv4 addresses that belongs to address block used for peering but that are not allocated to IXP users. Very useful tool for solving this issue is *ARP sponge* [4] developed by AMS-IX. This tool, written in Perl, listens on peering LAN for ARP traffic and when the number of ARP requests for certain IP address exceeds a threshold, it sends out an ARP Reply using its own MAC address. Final measure for controlling broadcast traffic is to setup ARP timeout timer to at least 4 hours. Changes of connected devices on IXP infrastructure are very rare, especially changing of port for the connection. Because of that, ARP timeout timer can be set to such a high value.

For the physical connectivity, optical cables are preferred media. Since the Ethernet ports should be 1G/10G, the best way (cheapest, smallest space is required) is to use SFP/SFP+ (Small Form-factor Pluggable Module) ports. And to be in position to monitor optical links on physical level, all ports and SFP/SFP+ modules should have DDMI (Digital Diagnostics Monitoring Interface) functionality which allows reading all technical parameters from optical interfaces. It is good practice to permanently monitor optical level on all optical ports via SNMP polling (not many vendors offer this feature). Those data are very useful for troubleshooting when the errors occurred. As example, Fig 1. represents degradation of attenuation of passive CWDM module.

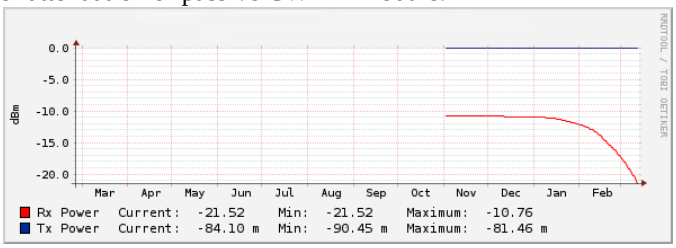

Fig. 1. CWDM passive module degradation over time

Regarding required throughput of the switch, market research should be done. Some statistics shows that 54% of IXPs in the world have traffic which is up to 20Gbps [5]. So, it is unwise to spend a lot of money for very powerful switch whose potential will not be used. SOX started with few Gbps of traffic in total, and today, after 6 years of growth, it is at 200Gbps of total traffic. SOX is not completely in accordance with statistics and that is the reason for recommendation for market research before starting this business.

Traffic analysis is one of very important function on IXP. The operator of IXP should have the proper tool to identify irregular traffic. To achieve that task, IXPs are using sflow analysis [6]. Sflow is abbreviation of "statistical flow" and represents one way for analyzing traffic that is passing the network devices. It analyze statistical sample of the traffic (e.g. every 8192nd packets). It is less demanding for the equipment than netflow but still generate good statistics and information about traffic. This is especial true in case of IXP with multi Gbps traffic. As a part of subsystem for traffic analysis, sflow collector should exist. There is a lot of commercial software for this purpose. SOX developed its own software based on pmacct [7] open source project. Advantage of in house software development is that the software can be tailored to fulfill all specific requests of operating IXP network.

Besides already mentioned features, few more are important for proper functioning of IXP. Ethernet switches should support SNMPv3 for network management, SSHv2 for

remote access to the switch, remote logging for sending all logs to central syslog server where logs should be analyzed and saved for the future use, port mirroring with preferably remote span extension for the purpose of traffic sniffing during the troubleshooting. Dual power supply is obligatory request for all equipment that should be part of critical Internet infrastructure.

III. IP Prefixes Exchange and BGP

As it is well known, BGP protocol is the major protocol for network layer reachability information exchange between ISPs denoted with Autonomous System (AS) numbers. When ISPs come to IXP, they might establish one BGP session with every member of IXP, which is huge administrative and technical work. Instead of this approach, the majority of IXPs are using route-servers for distribution of information about IP prefixes. Basic principle of work of IXP is presented on Fig. 2.

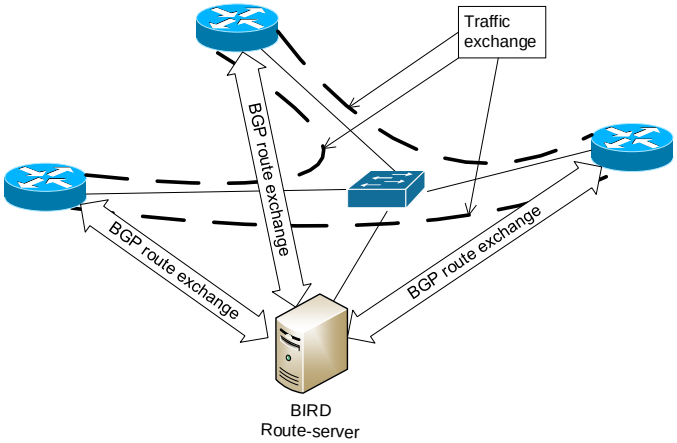

Fig. 2. Route-server in IXP network

Route-server is a simple Intel-based server connected to the same LAN as all other member's routers of IXP. Route-server is running BGP process in route-server mode and it has established BGP session with every router on LAN. In route-server mode, when BGP protocol receive IP prefix announcement from one BGP peer, it forwards it keeping the same next_hop attribute and without adding its own AS number to the AS_path attribute. Final result is that the traffic is going directly between routers and IP prefixes information are exchanged via route-server. In this setup every router has to establish only one BGP session with route-server. In reality, and for the purpose of redundancy, IXPs maintain two route-servers with the same routing policy. BGP protocol chooses the best route based on few attributes and one of the most important is AS_path attribute. AS_path contains all AS number through which this announcement passed. And the most preferred route is the one that has the shortest AS_path attribute. Since the traffic is forwarded directly between routers, this is the same situation as if they were directly connected. Because of that, best practice for the route-server is to remove IXP's AS number from AS_path attribute which is announced to the routers of IXP customers. The drawback of removing AS number is that standard BGP mechanism for detecting routing loops based on detecting AS number in AS_path attribute does not work. IXPs should implement different methods for detection of routing loops. Those methods are prefix tagging with specific community number and detection of it on incoming routing policies and exact route filtering on all incoming prefix announcements.

Additional feature of route-server is reflected in the fact that it has to maintain separate BGP table for every peering partner. Basic principle of route-server functioning is presented on Fig. 3.

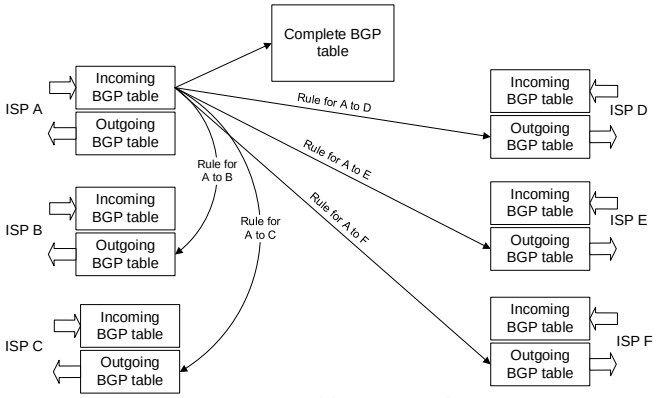

Fig. 3. Basic principle of functioning of route-server

Main task to achieve on route-server is to provide possibility for every ISP to independently exchange routing information with all IXP members. For that purpose, route-server has 2 BGP table for every peering neighbor, one is for incoming announcements and the other is for outgoing announcements. There is separate rule for distribution of IP prefix information between every two BGP tables on route-server (for clarity Fig. 1 shows only rules for the distribution information from incoming BGP table for ISP A toward all other outgoing tables on route-server). Route-server also has one common BGP table which is used for monitoring. There are tree well know open-source software for route-server: Quagga [8], BIRD [9] and OpenBGPd [10]. SOX is using BIRD software for its route-servers. BIRD software is dominant at IXPs around the world [1] and is optimize for integration with scripts.

Previously described scenario is minimal scenario for proper functioning of IXP. The operator of IXP has full control of all IP prefix information forwarding. But, this is not what the ISPs want. They want to have possibility to control announcement of their IP prefixes by themselves. That's the reason for implementation BGP community based control system. One of the BGP protocol attributes is community attribute which is well-known transitive attribute. Every IP prefix can be tagged with community attribute of some value and this can be done by ISPs. IXP operator should define the values of community attributes that will result with some specific action on route processing on route-server. The best current practice is that first two bytes of community attribute is AS number of IXP and second two bytes is specific value which is equivalent of required operation. For example, SOX

has AS number 13004, code 100 represents the action "do not announce route to ISP 10", code 101 represents the action "announce route with 1 SOX AS number prepend to ISP 10", etc. For blocking announcement of the route to ISP 10, it should have community 13004:100. Each route can have multiple community attributes which represents required handling policy of the routes on route-server. With community attribute system implemented on route-server every IXP member have full control of the announcement of their IP prefixes without direct access to the configuration of BIRD software on route-server. Novel development in this area is acceptance of Large BGP community [11] which allows more flexible mechanism for controlling BGP prefixes propagation. Problem with it is that still not all major vendors support it.

Nevertheless the foregoing description of the community based announcement control mechanism, some ISPs prefer to establish direct BGP session with IXP members. In principle, this does not interfere with normal operation of IXP, but many IXP operators insist that every IXP member must have BGP session with route-server. IP prefix filtering is an additional function of route-server which is very important for Internet stability. BGP protocol does not have any kind of route authentication which means that anyone can announce anything. There have been problems in the past that error in the configuration of the BGP protocol caused temporary loss of Internet access of some autonomous systems. In order to prevent similar events in the future, IXP has a responsibility to carefully control all the announcements of its members. The main method of control announcements is to generate IP prefix filters based on the information in Internet Routing Registry. Since ISPs do not keep IRR database in fully up-to-date state, manual tuning of route filters is a necessity. In addition to route filters, limiting the number of announced IP prefixes is another method of controlling the process of IP prefixes exchange. There is one tool specifically designed for operation of IXP by name IXP manager [12]. At the time being, SOX didn’t install it in the network management subsystem, but it is very useful software which helps the IXP operator to manage the network. The last measure of protection the LAN for peering (better known as peering LAN) between IXP members is not to announce peering LAN IP prefix to the Internet. IXP members have duty not to announce that IP prefix inside their network and outside to the Internet. This measure is protecting peering LAN from malicious activities coming without possibility of control/remedy, from the global Internet, thus reducing the possibility of various attacks, and improving troubleshooting of a problem, should it occur, obviously originating from the networks of IXP members. Problem of route-server operation are further addressed in RFC 7947 [13] and RFC 7948 [14], and SOX route-servers configuration is fully compliant with these recommendations.

IV. IXP Network Design

Equal importance of financial cost and redundancy in network topology in order to achieve high availability of IXP services is never ending story. At the beginning, IXP would typically start with one site and one Ethernet switch. As the time go by, traffic is growing, number of connection is increasing and, sooner or later, IXP have to expand to additional sites, which incurs both technological and financial questions. Opening a new POP (Point Of Presence), will enable more customer networks to connect, incurring both new revenue and new cost. As the number of POPs increase, topology should reflect market and traffic demands, retaining high availability, as there is just one switch. Biggest world IXPs like AMS-IX and DE-CIX become global IXPs with PoPs all around the world [15],[16].

Choice of fast re-route protocols is quite extensive, ranging from simple LACP (Link Aggregation Control Protocol), STP (Spanning Tree Protocol), RSTP (Rapid Spanning Tree Protocol), all the way to different MPLS options. After testing many options, we adopted well known KISS (Keep It Simple and Stupid) approach, over dimensioning backbone link and bonded multiple 10G links via LACP. If the new site is in the same city, we are talking about Metro Ethernet Network or, in case of another city, this becomes WAN network. In both cases, network topology should be carefully designed. First of all, internal interconnection, IXP backbone, links should have enough capacity to support growth of IXP traffic and to have requested availability. When we consider traffic, we are talking about tens of gigabits per second, so, dark fiber links or wavelengths in DWDM systems are the only viable choice. Fiber cut in today word is not rare situation. SOX's experience is that we have one fiber cut per week on average for international links. That imposes requirements for careful planning of network topology. Connection between sites should go over at least two physically different paths. Capacity of every physical link should be high enough to be in position to support total traffic in case of break of another link. It looks like network is over dimensioned but, since the traffic is constantly growing, capacity is not exaggerated. And availability of the service is one of the major requests for every IXP. Important question is which level of over dimensioning should be used when we are talking about link capacity. Choice of new IXP POP locations is often derived from suggestions of existing and new potential IXP members/customers, stressing once more importance of communication, collaboration, and cooperation. Adopting this open, and sometimes difficult and lengthy process, IXP upgrades its customers into members/partners in joint activity, tailored toward their exact needs. Very difficult for engineering part of the company, but very important for the whole IXP existence. Practice shows that operators are using management systems that measure 5 minute average traffic. Problem with this approach in case of Internet traffic is its burstiness. Traffic measurements carried out in SOX network shows that intermittent increase of the traffic can go up to 3 times of 5 minute average. Based on all this results, SOX has

adopted the rule that the link should be upgraded when the maximal traffic reach 50% to 70% of link capacity. Based on these recommendations, SOX internal network design is presented on Fig. 4.

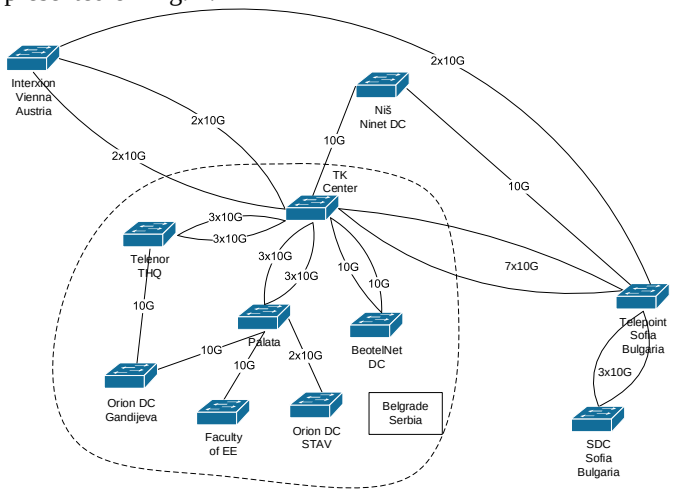

Fig. 4. SOX network topology

V. IXP Services

IXP exists primary because of customers or members (name depends on formal organization of IXP). And the primary service is peering between ISPs connected to the IXP. Everyday development of the Internet pushes IXPs to expand its service portfolio. With the raise of popularity of multimedia content, CDNs became crucial. CDNs main task is to be as close as possible to as much as possible end users, and the right place to achieve that task is to connect CDN to IXP. Besides ISPs, CDNs are the second most important element of IXP. More CDNs are connected to IXP, more ISPs will come to connect to that IXP. Two approaches can be used for connecting CDNs to IXP. On large IXPs, CDNs are using their own routers for connection. On smaller IXPs, CDNs install only caching servers and IXP is responsible for CDN traffic routing. This requests one new element in IXP architecture - router. Standard approach is to buy brand name router (such as Cisco, Juniper...) which is expensive solution acceptable for big ISPs, yet not so affordable for an small, just established IXP. In case of small IXP, price is very important element in decision process. Alternative solution for router is software router based on Linux and BIRD [9]. Limitation of software based router is 3Mpps (Mega packets per second) of throughput with equivalent 16Gbps throughput of real traffic on IXP [17]. The price of software based router is significantly lower than the price of brand name device and the performances are good enough for small IXP. SOX is using software based routers for some of the services with very good results.

Very important service for IXP is hosting anycast root DNS servers. In the process of end user accessing to any content on the Internet, first step is to contact local resolving DNS server which contact root DNS server. If the root DNS server is far from local DNS, significant latency is introduced in Internet access, and diminishes end user experience. Positioning root DNS server on local IXP decrease latency to only few milliseconds which increase the quality of experience for end users. SOX is hosting 4 anycast root DNS servers on its network (I-, J-, K- and L- root DNS servers) and it resulted with significantly faster Internet response in the region. Besides that, SOX's customers are hosting few more root DNS servers which make SOX infrastructure very well covered with this type of service.

Further expansion of SOX IXP was in the direction of interconnecting with other IXPs. Interconnection of two IXPs that are Layer 2 based is not a simple task as establishing the cooperation, high performance router is required. This router must have high throughput, support of BGP protocol and powerful mechanism for route announce/acceptance. If we want to have full IXPs integration, this router should have possibility to delete its own AS number from AS_path attribute. By removing AS number while announcing prefixes to other IXP, who is also removing its AS number when announce something to the IXP customers, IXP customers would see like they have direct peering session with customer of neighboring IXP. Here stay the same remarks as previously - since the AS number is removed, another method of detecting routing loops should be implemented. SOX implemented direct connection with few regional IXPs which increase the traffic volume on all IXPs in cooperation and advance regional traffic exchange.

As more and more traffic is passing IXP network, it becomes natural place for DDoS mitigation and protection systems. DDoS mitigation system can be installed anywhere in the network. But, if it is installed at end user network, it would be useless to protect network from saturation of Internet links. Because of that, DDoS mitigation system should be installed closer to Internet backbone where the links have enough capacity to overcome DDoS attack. And natural place is IXP network. Generally speaking, IXP links have high capacity to survive DDoS attack. When the DDoS mitigation system filters malicious traffic, regular traffic can be forwarded to the end user without saturation of the user's link. As the IXP grow, DDoS mitigation system become a must have service.

VI. Lessons Learned

In previous paragraphs, best practice knowledge is presented. Besides that, there are some lessons that we learned and that cannot be found in any best practice document. L2 filtering functionality is part of almost all brand name Ethernet switches. Unfortunately, many implementations of this function do not work properly. In worst case, it does not work at all, and in some of cases, it works partially. Since this is very import function for IXP, it should be tested before starting with operational work. And switch throughput should be checked also. We tested some Ethernet switches with specified throughput of hundreds of Gbps which was overloaded with 8Gbps. This is especially problem if we are dealing with bare-metal switches, which are very popular these days because of very good price/performance ratio.

One important lesson was learned on using DAC (Direct Attach Copper) cables for 10G Ethernet. This cable is very cheap and viable solution for interconnection of the devices inside the rack cabinet. But, this cable is consuming more energy than the fiber optic interface. We connected two Ethernet switches with DAC cable for 10Gbps. When the switches were connected, everything was working correctly. Traffic increased till 4,5Gbps when the problem started. One of the switches (we'll call it A) started detecting line down, while the other one (switch B) keep the line active all the time. What was the problem? Line driver on 10G SFP+ port on switch B did not have enough power to feed DAC cable when the traffic increase (higher traffic consume more power) and the voltage on the cable was lower than it should be. Switch A detected that as the line down and stop sending traffic. As soon as the traffic stop, switch B got enough power to feed the DAC cable and the traffic could continue normally. This resulted with link flapping when the traffic increases. Changing DAC cable with the new one didn't solve the problem since it was not the problem at all. Instead of DAC cable, we put multimode 10G SFP+ module and multimode optical patch cable and the problem was solved permanently (multimode SFP+ module consume less power than the DAC cable). Since the price of multimode SFP+ module decreased significantly and it is comparable with the price of DAC cables, our recommendation is not to use DAC cable at all, use multimode cables.

Sflow statistics are already mentioned as important information for operation of IXP. Our testing shows that not all switches generate valid sflow statistics of the traffic. Comparing with number of bytes counted on interface, the difference goes up to 60%. And this was especial case with bare-metal switches. Since gathering of sflow statistics is resource intensive task, it looks like bare-metal switches are not optimized for this function. We even noticed that some switches are sending sflow packets without all necessary data, like VLAN identification of the traffic was missing. We learned that this feature should be deeply tested before use of the switch.

At last but not the least, close cooperation with IXP members is crucial, network neutrality, and open procedures, as well as collaboration with major Internet companies, like ICANN, RIPE, Verisign, ISOC, Netnod, and respective CDNs, are proving to be very beneficial. Regular meetings with IXP members, empowering members with traffic control features, but also including members into decision making process building community is equally beneficial. Presenting latest technical and technological solutions, as well as introducing best practices, equally in operational excellence, and in educational events constitute second pillar in building successful IXP, while first pillar being superb highly available IXP service described in detail in this article.

VII. Conclusion

This article presents all the best practices that we accepted and implemented during the operation of the SOX IXP. Besides all technical issues previously mentioned, one very important thing for every IXP is open connection policy which is publicly announced. Good relationship with local community is necessity to achieve their confidence in your work. Without good communication, collaboration and cooperation with local community no hardware neither software can help in establishing and successfully operating IXP.

Acknowledgment

The author wish to thanks Jane Coffin from Internet Society, Martin Levy from CloudFlare, Kurt-Erik "Kurtis" Lindqvist from LINX, Veni Markovski from ICANN, and Arnold Nipper from DE-CIX for significant help and support at the beginning of SOX.

One Solution for Fast Reroute in OpenFlow Networks

Nataša Maksić and Aleksandra Smiljanić, *Member, IEEE*

***Abstract*—This paper presents a solution for fast reroute in the implementation of Ethernet switching fabric based on OpenFlow. This solution adds fast traffic protection by using OpenFlow Fast Failover groups. The paper presents our design for improved reliability in software defined networks (SDN), and describes its implementation.**

***Index Terms*—OpenFlow; Fast Reroute; Ethernet.**

I. Introduction

TELECOMMUNICATION devices have grown in complexity over the past decades and introduction of new ideas has grown harder in the process. The packet switching devices became complex products manufactured by large companies. They became inaccessible for researches whose goal is to implement and evaluate some of the emerging ideas in packet forwarding. OpenFlow was introduced as an answer to this problem: it is a protocol which would enable configuration of packet matching and processing from a remote controller. This would eliminate need to write the software executing on the packet switching device, and enable simpler implementation of new algorithms which would control packet forwarding.

We have proposed implementation of the Ethernet switching fabric using OpenFlow ([1]-[3]). The standard network of Ethernet switches would be based on spanning tree protocol and learning switches. Due to the spanning tree protocol, it would be able to use only selected subset of links which do not form loops. Hence, there would not be more than one path between any two switches. Such architecture would not be suitable for achieving high performance. Our proposed solution is based on using Proxy ARP and aggregate flows, which provides the same service as standard Ethernet switches to the attached users. At the same time, it has the ability to direct packets according to the selected algorithm, in order to achieve high performance. In [1] and [2], we describe flow establishment based on LB-ECR algorithm for data center networks. In [3], we describe an algorithm for adaptive flow routing.

The important property of high performance networks is fast reaction to network failures. In standard Ethernet networks, link failure requires the recalculation of the spanning tree, which has the potential to disrupt traffic across the network for seconds. When transmitting time critical flows we wish to reduce downtime to less than 50ms. In packet networks, such traffic protection can be accomplished by fast reroute techniques. Fast reroute techniques enable redirection of the traffic in the packet switching device which detected failure.

Principle of OpenFlow is that the calculation of forwarding paths is performed by the controller. However, if a controller would perform traffic redirection, the message containing information about the failure would need to be carried to the controller and processed by the controller. Then, the controller would need to send messages to the device in order to redirect traffic. Such procedure could not be performed in short time period. Hence, the OpenFlow standard provided ability to perform fast traffic redirection based on link failure. This feature is called OpenFlow Fast Failover group and it was introduced to the version 1.1 of the OpenFlow standard [4].

Fast reroute is not a novel technique. It is well established and deployed in MPLS networks. RFC 4090 describes varieties of MPLS fast reroute and elements of RSVP-TE protocol for the configuration of MPLS fast reroute. Also, IP fast reroute is an active area of research, with the goal to provide fast traffic protection within IP packet routing.

The manufacturers of routers have implemented MPLS fast reroute and, to some extent, IP fast reroute techniques. The algorithms for finding protection paths for MPLS are implemented in routers, and proven in practice. Hence, the established algorithms for fast reroute can be applied to OpenFlow networks in order to provide fast traffic protection. These algorithms can provide OpenFlow networks with fast traffic protection needed by high performance applications. Flexibility of OpenFlow will enable further development of these algorithms, and possibly further increase in packet forwarding performance. In this paper, we implement our proposed solution in Ryu OpenFlow controller [5], and evaluate it using Mininet [6].

Section II presents an overview of the related work in the area of OpenFlow traffic protection. III introduces OpenFlow Fast Failover groups. Section IV presents the solution proposed in this paper. This section firstly describes OpenFlow network for which the fast traffic protection is implemented. Then, it describes configuration steps for protection in OpenFlow network, and illustrates the protection flows on an example. Section V describes evaluation of the protection configuration. Chapter VI contains conclusion.

II. Related work

Paper [7] proposes a solution which incorporates establishment of secondary route by the controller. This solution uses BFD [8] for failure detection. It uses OpenFlow Fast Failover groups and precalculated secondary paths to provide fast protection. The controller would perform recalculation of new paths after it receives information about the failure.

Paper [9] proposes introduction of aggregate flow which would carry traffic of all affected flows around a failure. In this case, authors propose reconfiguration instead of protection, i.e. they do not use Open Flow Fast Failover groups. Instead, they rely on the controller to reroute the flow to the new path, and redirect traffic from failed link to this path.

In paper [10], authors use OpenFlow Fast Failover groups to redirect traffic. The controller periodically recalculates path of protection flows. Additionally, authors propose periodical rerouting of traffic flows in order to avoid congestion.

Paper [11] proposes an algorithm for calculation of backup paths which incorporates current queue lengths. These queue lengths are converted to link distances and used in Dijkstra algorithm. Authors do not use OpenFlow Fast Failover groups, and redirection of the flow affected by failure to backup path is performed by controller.

Paper [12] describes OpenFlow solution which uses OpenFlow Fast Failover groups for fast flow protection followed by the flow recalculation and reconfiguration performed by the OpenFlow controller.

Some papers propose the modification of the OpenFlow protocol in order to improve protection capabilities. In paper [13], authors argue that OpenFlow Fast Failover mechanism is not adequate since local detour paths may not be available or may be inefficient. They propose OpenState, an extension to OpenFlow in which internal switch state is added to flow match criteria, and this state can be changed as a part of flow actions. By using such state machines, authors propose a scheme for redirecting packets from nodes that precede the node that detected failures on the OpenFlow path. In paper [14], authors propose OpenFlow protocol extension in order to provide fast monitoring, and end-to-end protection of the path instead of fast reroute protection.

So, the idea of fast reroute protection is well known and established. In OpenFlow, its implementation needs to be adapted to the particular OpenFlow design.

Since fast reroute is well established in MPLS, many of the papers in area of OpenFlow protection are based on the concepts known from MPLS fast reroute techniques. RFC 4090 defines two varieties of fast reroute traffic protection: Facility Backup and 1-to-1 backup. Facility Backup is further split into link protection and node protection. The main difference between the two varieties is that in Facility Backup, packets from multiple LSP affected by failure are transmitted through one protection LSP. In 1-to-1 backup, each protection LSP carries traffic of one LSP affected by failure. Reconfiguration after failure plays important role in MPLS. Reconfiguration can be performed after fast reroute in order to find new paths for the traffic, or it can be used instead of protection if the duration of the downtime is not critical. Ideas from MPLS fast reroute are used in OpenFlow solutions. OpenFlow solution proposed in [9] is similar to MPLS Facility Backup, and OpenFlow solutions proposed in [7], [10]-[13] are similar to 1-to-1 MPLS protection.

III. OpenFlow Fast Failover

OpenFlow standard has enabled traffic redirection in case of failure without the need for controller actions. This redirection is performed using OpenFlow Fast Failover Groups. Fast Failover Groups are introduced in the 1.1 version of the OpenFlow standard [4].

Fast Failover Group contains list of buckets. Each bucket contains specification of port which is monitored, and set of actions to be performed if the port is in the operational state. At each moment in time, one of the buckets with the port that is available is used. Buckets are sorted, and the system chooses the first bucket in the list with the port that is in the operational state. Typically, two buckets will be configured, one for protected path, and one for protection path.

The controller needs to configure groups, primary and secondary path in advance, and the switch will redirect traffic to secondary path after the detection of the failure. This will protect the traffic in the case of failure. In the meantime, the controller will receive information about the failure; and, depending on the algorithm, it may perform reconfiguration of the affected flows.

The failure detection mechanism is not defined within the OpenFlow group interface. Open vSwitch has the ability to use BFD [8] to detect failure. The advantage of using BFD is that it monitors not only the physical state of the link, but also the functionality of the neighboring switch. Packet processing in Open vSwitch is described in [15]. Open vSwitch can process certain packet types independently of OpenFlow tables. These packet types include BFD. In this way, we can use BFD for fast detection of the state of link, and neighboring switch. The detection speed is determined by the interval between BFD messages, and the timeout interval after which the port is transferred to the failed state, and the traffic is redirected to the protection path.

IV. Elements of the OpenFlow implementation

A. Proxy ARP and Aggregate flows

Our OpenFlow implementation performs the functions of Ethernet switching fabric. Such network can be deployed in high performance computer networks, such as data center networks. In comparison with the standard Ethernet networks, OpenFlow network can apply various flow forwarding algorithms in order to improve communication performance.

The computers attached to the switching fabric need to observe this switching fabric as a network of standard Ethernet switches. Proxy ARP function enables computers to learn each other's Ethernet addresses, and to start IP communication. This function is implemented through the controller. The switch forwards an ARP request to the controller, which, then, sends the requests from other switches

to the computers attached to those switches. When the ARP reply is received on one of the switches, the controller instructs the switch attached to the computer that issued the request to send the ARP reply to this computer. When the controller receives ARP request or ARP response it stores information about server IP and Ethernet address as well as to which switch and which port of that switch the server is connected. This information speeds up Proxy ARP procedure and expires after predefined time period. The details of implementation of Proxy ARP functionality using Ryu controller are presented in [1].

First IP packet of the application flow which arrives to OpenFlow switch is forwarded to the controller. In our implementation, the controller assigns application flows to aggregate flows. One aggregate flow can carry more application flows. There may be more than one aggregate flow between two computers. Aggregate flows are established in advance. Application flows are assigned to aggregate flows according to selected flow routing algorithm. Our implementation of the creation of aggregate flows using Ryu controller is described in [1].

The aggregate flows enable faster creation of new application flows. Controller needs to modify flow tables only in switches attached to communicating computers. In the switch attached to the computer that sent first IP packet of the flow, the controller creates OpenFlow rule to include outgoing packets of the application flow to selected aggregate flow. In the destination computer of the IP packet, the controller creates OpenFlow rules to extract packets of the application flow from the aggregate flow and to forward them to the port where the destination computer is attached. It should be noted that behind OpenFlow switch port, we can have Ethernet network with more than one computer.

B. Fast Reroute

Design of fast reroute includes creation of flows that will carry packets of the flows affected by failure. In this proposal, we carry traffic of one aggregate flow with one protection flow. In fast reroute, the node that detects the failure also redirects packets to protection flows. Hence, we need to create protection flow from each of the switches on the aggregate flow path in order to provide protection from any failure on the path. We can separate three cases for this configuration: first switch of the aggregate flow path, last switch of the aggregate flow path and intermediate switches. In each of the switches with the exception of the last switch on the path, we create OpenFlow Fast Failover groups.

Fig. 1 shows the Ryu code for creation of the OpenFlow Fast Failover group. This group contains two buckets. It selects one of two ports. Ports are represented by integer identifiers stored in variables port1 and port2. References of objects and methods used in Figure 1 are taken from the Ryu documentation [5]. Object parser used in Fig. 1 represents the OpenFlow protocol.

In Fig.1, we first define the Python list named *buckets* that will contain instances of object OFPBucket. The constructor for this object takes parameters *weight*, *watch_port*, *watch_group*, *actions*. We use value 0 for the parameter *weight* since this parameter is standardized for OpenFlow Load Balancing groups, and it is not important for Fast Failover groups. The second parameter, *watch_port* is the identifier of the port which is monitored for failure. This parameter receives the port identifier. The third parameter, *watch_group*, defines the group that is observed for failure. The group is considered failed if all of its buckets are failed [16]. Since we are not interested in monitoring groups, we use the value of proto_v1_3.OFPGT_ALL for this parameter. The last parameter in the constructor for object OFPBucket is *actions*. This parameter contains the list of actions that will be performed if the bucket is selected based on the states of the ports in the Fast Failover group.

```
buckets = []
b= parser. OFPBucket (0, port1,
        ofproto_v1_3.OFPP_ANY, actions1)
buckets.append(b)
b= parser. OFPBucket (0, port2,
        ofproto_v1_3.OFPP_ANY, actions2)
buckets.append(b)
group=parser.OFPGroupMod(datapath,
        ofproto_v1_3.OFPGC_ADD,
        ofproto_v1_3.OFPGT_FF,
        group_id,
        buckets)
datapath.send_msg(group)
```

Fig. 1. Creation of OpenFlow Fast Failover group.

In Fig 1, we create two buckets, one for the port that belongs to the protected aggregate flow, and the other for the port belonging to the protection flow.

After the buckets are created, we can create Fast Failover group. For this purpose we create object of the class OFPGroupMod. The constructor for this object has the following parameters: *datapath*, *command*, *type*, *group_id* and *buckets*. Parameter *datapath* identifies the switch to which the command will be sent. Parameter *command* defines operation which should be executed on the group. Possible values of this parameter are OFPGC_ADD, OFPGC_MODIFY and OFPGC_DELETE [16]. Since we are creating new group in Fig. 1, we use the value OFPGC_ADD. The parameter *type* defines type of the group. Possible values are OFPGT_ALL, OFPGT_SELECT, OFPGT_INDIRECT and OFPGT_FF [16]. Since we are creating the Fast Failover group, we use value OFPGT_FF. Parameter *group_id* contains the integer identifier of the group. Finally, parameter *buckets* contains the list of buckets in the group that was previously created.

After the object group is created, it can be sent to the switch using method *send_msg*.

When creating buckets, we obtain two ports from the calculated paths of aggregate flow and protection flow. The OpenFlow actions assigned to buckets will differ in the output ports to which packet should be forwarded, and in the actions regarding addition of VLAN tags.

First, we will observe the case of the switch connected to server, and we consider configuration for the reception of packets from the server. Configuration for the case without protection is described in [1]. For the case with protection, the match rules stay the same. For TCP and UDP traffic, they

specify input port, protocol type, source and destination IP address, as well as the source and destination port. For the case with protection, the action for this match is a reference to the OpenFlow Fast Failover group. This group monitors two ports, and has one set of actions for each port. These sets of actions are based on the set of actions for unprotected case, described in [1]. According to the Proxy ARP procedure [1], they set the MAC address to the MAC address of the destination server, add VLAN tag of the aggregate flow and forward packets to the switch output port. In the Fast Failover group, these two sets use different values for the VLAN tag and output port corresponding to the protected path and the protection path. So, we observe paths as unidirectional, and in the first switch on the path, the Fast Failover group directs traffic either to the protected path or protection path.

In the intermediate switches along the protection path, between the first switch and last switch, the Fast Failover groups have also two entries. One entry directs traffic along the protection path. In the case of failure of the next hop on the protected path, the second entry directs packets on the protection path. Configuration for intermediate switches without protection is presented in [1]. Match is performed based on the input port and tag value, and the action is forwarding packets to the appropriate ports. With protection, match remains the same. Action for the protected path is to forward the packet to the port on the protected path. However, actions for the protection path include two steps: changing the tag of the packet and forwarding the packet to the port. In Fig. 2, we can observe creation of the actions list for the protection path in Ryu controller.

```
actions2 = [parser.OFPActionSetField
(vlan_vid=(vlan2 | ofproto_v1_3.OFPVID_PRESENT)),
parser.OFPActionOutput(out_port2)]
```

Fig. 2. Actions for protection flow

Finally, in the last switch of the unidirectional path, Fast Failover groups are not used. The switch only needs to extract packets from the protected flow, and from each of the arriving protection flows in the same way as in [15].

In the intermediate switches of the protection path, the match and actions are defined in the same way as for the intermediate switches of the protected path.

C. Traffic restoration

OpenFlow specification states that in Fast Failover groups, the switch will execute actions from first bucket with the port that is operational [16]. The first bucket is defined as the highest priority bucket. The first bucket contains actions for the protection path. After the failed link or switch is repaired, the traffic will automatically be returned to the primary path.

Transfer of traffic to the protection path may lead to the increased traffic on some link. In some solutions, for example [3], the controller continuously monitors link utilizations and performs necessary actions to avoid congestions. Such algorithms may also be applied to the paths using the protection. If the controller detects the possibility of congestion it can calculate new path for protected flow or protection flow and configure this path in the OpenFlow network.

D. Example protected flow

For illustration of the flow protection, we will observe network shown in Fig. 3.

In Fig. 3 we have six OpenFlow switches. We observe two servers connected to switches S1 and S4. These two servers need to communicate. According to the algorithm, the controller will assign communication between these two servers to aggregate flow with the path S1-S2-S3-S4. Both directions of this flow use the same path.

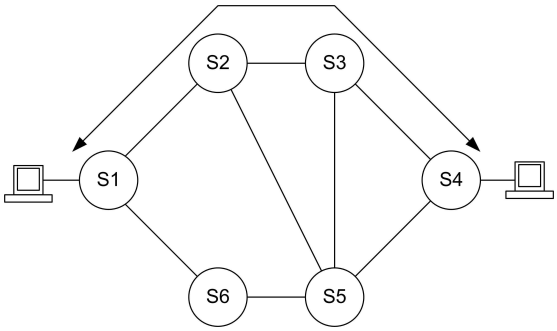

Fig. 3. Example flow which is required to be protected

In our implementations, two directions of the flow will be protected independently. Fig. 4 shows one direction of the flow and protection flows for that direction. Protected flow is drawn with a full line, and protection flows are drawn with the dashed line. Each of the protection flows provides protection for failure detected in one of the switches along the protected path. In Fig. 4, values of the flow tags are shown. The protected flow in direction from S1 to S4 has tag 1. In our implementation, tag is carried in the VLAN identification field of the Ethernet header. The protected flow that starts from switch S1 has tag 3. This flow will be used if switch S1 detects the failure. Hence, the flow with tag 3 protects from failure of the link between switches S1 and S2, or from failure of the switch S2.

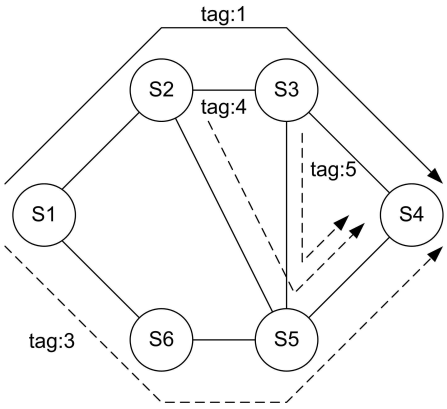

Fig. 4. Protection paths in one direction of the flow

The flow with tag 4 is a protection flow for failure of the link S2 to S3 or failure of the switch S3. Finally, the flow with tag 5 is a protection flow for failure of the link S3 to S4. We

cannot create protection from the failure of switch S4, because the flow has to use this switch.

In Fig. 5, we can observe the protected path from switch S4 to S1 with tag 2, and protection paths with tags 6, 7 and 8.

V. Evaluation using Mininet

We have validated operation of the described algorithm using Mininet [6]. Mininet setup which we use is described in [3]. Based on this setup we can evaluate the configuration generated by the controller in different topologies. For the topology presented in Fig. 3, we can generate traffic in Mininet virtual hosts, activate and deactivate links in the evaluation network using the Mininet terminal. For example, we can simulate failure of the link between switches S2 and S3 using command "link S2 S3 down", and confirm that the protection works.

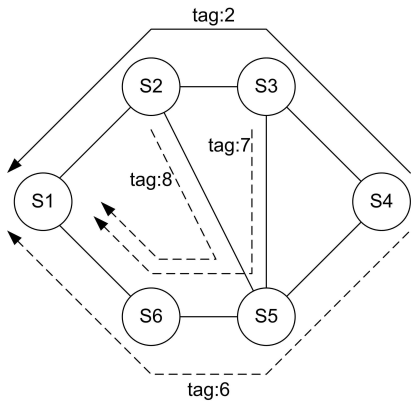

Fig. 5. Protection paths in the second direction of the flow

In this development environment, we can observe configuration of switches and transmitted traffic in flows. For example, by issuing command "sudo ovs-ofctl -O OpenFlow13 dump-groups S1", we can observe the configuration of the OpenFlow group in the first switch of the path. This command is issued in the Mininet virtual machine. Fig. 6 shows the output of this command.

```
group_id=1,type=ff,bucket=watch_port:"S1-
eth1",actions=set_field:00:00:00:00:00:02-
>eth_dst,push_vlan:0x8100,set_field:4097-
>vlan_vid,output:"S1-eth1",bucket=watch_port:"S1-
eth2",actions=set_field:00:00:00:00:00:02-
>eth_dst,push_vlan:0x8100,set_field:4099-
>vlan_vid,output:"S1-eth2"
```

Fig. 6. Configuration of the OpenFlow Fast Failover group in the first switch of the path

In Fig. 6, we can observe configuration of the OpenFlow group created at switch S1 by implementation of the proposed algorithm at the controller. We can observe that the group type is ff (Fast Failover), and we can observe the configuration of two buckets. The first bucket monitors the state of port eth1, which is the port toward switch S2 and belongs to protection path. The second bucket monitors the port eth2 which connects the switch S1 with the switch S6, and belongs to protection path. According to the Proxy ARP algorithm [1], both sets of actions set the Ethernet destination address to the address of the destination server. Also, both sets of actions add tags to the packet. Values of the tags differ, one tag is assigned to the protected path and one is assigned to the protection path. Finally, both sets of actions forward packets to the output ports. Higher priority bucket belongs to the protected path and forwards packet towards switch S1. The second bucket belongs to the protection path, and forwards packet to switch S6.

An example of configuration of Fast Failover groups in the intermediate switch along the path is shown in Fig. 7.

```
group_id=0,type=ff,bucket=watch_port:"S2-
eth2",actions=output:"S2-eth2",bucket=watch_port:"S2-
eth3",actions=set_field:4100->vlan_vid,output:"S2-eth3"

group_id=1,type=ff,bucket=watch_port:"S2-
eth1",actions=output:"S2-eth1",bucket=watch_port:"S2-
eth3",actions=set_field:4104->vlan_vid,output:"S2-eth3"
```

Fig. 7. Configuration of Fast Failover groups in switch S2

If Fig. 7, we can observe two groups at switch S2. One group protects the flow in one direction, and the other in another direction. In Fig. 4, it is shown that the protection path with tag 4 starts at switch S2. The protected path and protection path in switch S2 are configured by the first group in Fig. 7. In Fig. 7, the action rule for the second bucket contains action set_field:4100->vlan_vid which changes the value of the packet VLAN tag. By setting the value 4100, the rule set the following values inside the VLAN tag: it sets the DEI (Drop Eligible Indicator) bit to 1 and the VID (VLAN Identifier) field to 4. Since bits in the VLAN tag are processed by the OpenFlow standard, the DEI bit has not the meaning it had in standard Ethernet. In the OpenFlow specification [16], this bit is called OFPVID_PRESENT, and it indicates that the VLAN identifier is set.

Similarly, the second group in Fig. 7 corresponds to the flows in Fig. 5. The first bucket in this group corresponds to the protected flow with tag 2 and the second bucket corresponds to the protection flow with tag 8. The action for the protected path is to forward unmodified packet towards switch S1. The action for the protection path is to change value of VLAN identifier from 2 to 8 and to forward packet toward switch S5.

VI. Conclusion

This paper presents one solution for traffic protection in OpenFlow networks. Presented solution uses OpenFlow Fast Failover groups and it is based on Ryu controller. The proposed solution is built on the previous work by the authors of this paper on the creation of the OpenFlow Ethernet switching fabric [1]-[3].

The target application of the proposed OpenFlow switching fabric are data center networks [1]-[3]. Application of OpenFlow in data centers enables customization of the packet forwarding algorithms based on specific needs of the data center. Such customizations could increase the performance

and utilization of the communication network in data center. The introduction of fast traffic protection adds important new component which could be used in a design of such new algorithms. Using OpenFlow Fast Failover groups, the traffic can be redirected around the failed link or switch much faster than in standard Ethernet networks.

ACKNOWLEDGMENT

This work was supported within the project TR-32022 by the Serbian Ministry of Science and Education, and by companies Telekom Srbija and Informatika.

Implementation of the MPLS Label Switching Procedure for the High-Speed Software Routers

Mihailo Vesović, *Graduate Student Member, IEEE,* Hasan Redžović, *Graduate Student Member, IEEE,* and Aleksandra Smiljanić, *Member, IEEE*

***Abstract*— Software routers are preferred over the classical routers when high flexibility and low costs are the requirements. Software routers are usually developed for the general purpose computers, which run standard operating systems not optimized for high-speed packet processing. For this reason, the fast I/O frameworks are used to speed up the data plane. In this paper, we have implemented Multiprotocol Label Switching (MPLS) procedure using the Data Plane Development Kit (DPDK) fast I/O. MPLS has a good synergy with the software routers as it is lightweight, scalable and protocol-independent. Our goal is to show its maximal forwarding speeds in such environment.**

***Index Terms*—Data Plane Development Kit, Fast I/O, MPLS Protocol, Software Routers**

I. Introduction

ROUTERS can be defined as a dedicated hardware devices used to perform the routing functionality. Logically, the router device is composed of the three main parts – control, data and management plane. The data plane is used to forward the traffic, while the control plane is used to decide on the routing paths. The management plane is focused on the device configuration and monitoring. Software routers use general purpose computer instead, and implement functionalities of all three planes in software. Single server (or workstation) with multiple network cards, operating system and routing software can be considered as a fully-fledged software router.

There are many candidates for the software control plane. Protocol suites like Quagga [1], BIRD [2] or Xorp [3] are all promising candidates, as they are open source projects. Management plane can be completely custom program. Unlike the control and management planes, the design of the data plane is more problematic, as it requires high packet processing speeds. Even though the standard operating systems have their own network protocol stacks, their performance is not adequate. The maximum achievable IP packet forwarding rate of the Linux protocol stack is around 4 Mpps (Mega packets per second) [4], which can be enough if 1 Gbit/s Network Interface Cards (NIC) are used. However, currently deployed servers usually have multiple 10 Gbit/s NICs installed, each of which requires the processing speeds of at least 14.88 Mpps per port.

The reasons why the Linux protocol stack is slow are multiple: expensive system calls, packet replications, additional metadata, etc [4]. In the recent years, fast I/O frameworks were developed in order to speed-up the data plane processing. Commonly used fast I/O frameworks are netmap [4], Data Plane Development Kit (DPDK) [5] and PF_RING [6]. The main idea is to pass the slow network protocol stack, and deliver the packets directly to the user application. This allows users to write their own packet processing software, tailored to their specific needs. The fast I/O frameworks process packets in batches, which significantly reduces the system call overhead. Additionally, packet replications are avoided, as well as the unnecessary memory allocations [4]. We can conclude that the data plane can be implemented as the combination of the high performance I/O framework and the user-space application, while the control plane can be any of the standard control plane suites, e.g. Quagga.

Multiprotocol Label Switching (MPLS) protocol inherently has some noteworthy properties which are of interest for software routers. The main advantage is that MPLS tunnels allow the packets to be forwarded on the additional paths, not only the shortest ones. As a consequence, it can be used to implement traffic engineering, which can improve link utilization and resiliency of the network. MPLS is classified as the layer 2.5 protocol and it can be used to encapsulate any other layer 3 protocol. Thus, backbone routers in the MPLS network (LSRs – label switched routers) are not required to know how to process any underlying protocol. This allows the backbone hardware infrastructure to be unified. Additionally, backbone routers do not need to have the complete Internet Protocol (IP) routing tables, reducing the memory consumption. MPLS also helps in the creation of peer-to-peer Virtual Private Networks (VPN) [7].

IP based routing is the standard in the today's networks, but the IPv4 longest prefix matching lookup can be expensive. It is necessary to use specific data structures, like multibit tries, in order to simplify the lookup process. Lookup is performed by traversing the tree from the root to the leaves until the most specific route is found. The lookup operation has a complexity of $O(W/k)$, where W is the IP address length, and k is the stride size. However, the insertion and deletion of routes are complex procedures which require the reorganization of the

Mihailo Vesović is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11120 Belgrade, Serbia (e-mail: mikives@etf.rs).

Hasan Redžović is with the Innovation Center of School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11120 Belgrade, Serbia (e-mail: hasan.redzovic@ic.etf.bg.ac.rs).

Aleksandra Smiljanić is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11120 Belgrade, Serbia (e-mail: aleksandra@etf.rs).

tree, with complexities of $O(W/k + 2^k)$. Memory consumption, on the other hand, can be as high as $O(2^k NW/k)$ for a set of N prefixes [8].

On the other hand, MPLS lookup is much simpler. MPLS labels have a local meaning in the network. Inside the MPLS network, the routing is performed solely on the MPLS label, rather than the IPv4 destination address. The packets are routed via a Label-Switched Path (LSP), which is set up by some control protocols, such as Label Distribution Protocol (LDP) [9] or RSVP-TE [10]. MPLS lookup and table updates can be performed in the $O(1)$ time [11]. It is best to use direct lookup, as there could be not more than 2^{20} possible labels. In this way, the memory consumption is limited as well. Direct lookup can be implemented as the data read from the memory address which corresponds to the MPLS label, i.e. the MPLS lookup is a simple array indexing.

In this paper, we have implemented the MPLS label switching procedure for the backbone software routers using the DPDK. Our implementation is a natural extension of the DPDK *l3fwd* application, and as such, it is parallelized. In our previous work [12], we have implemented IPv4 lookup procedure using the netmap framework. This application was parallelized using the OpenMP, where we have leveraged the advantages of the Receive Side Scaling (RSS) to disperse the packets across the multiple receive (RX) packet queues. We have also implemented MPLS forwarding for the netmap platform [13], but this implementation was only single-threaded with the limited performance. In this paper, we will show that our MPLS DPDK label switching application outperforms both of our previous solutions even without the RSS capability, for a single RX ring per input interface.

II. Fast I/O With the DPDK

DPDK (Data Plane Development Kit) is the set of libraries and drivers for the high-speed packet processing. DPDK allows the creation of network applications which require fast packet handling, for example high-throughput software switches or routers. It can be used with Linux and FreeBSD operating systems and it supports most common computer architectures [5].

The unique programming interface is available to the user via the EAL layer (Environment Abstraction Layer). The EAL hides the specific details from the users, thus allowing them to easily develop network applications. DPDK uses run-to-completion model. In this model, the core is polling for the packets on the input through an API, which are, afterwards, processed by the same core and forwarded to the specific output. Using the DPDK structures, pipelined processing can also be implemented.

DPDK allows the efficient utilization of CPU cores through the creation of multithreaded applications. The main thread is designed for the resource allocation (e.g. ring or mempool structures), which the other threads will use. DPDK application has at least one logical core thread (lcore), which is the instance of the application that is running on one core.

Interfaces, i.e. ports can have multiple receive and transmit (TX) queues associated with them, which allows parallel processing. During the configuration phase, the number of RX/TX queues is specified for each interface, as well as the number of descriptors per queue. Queues are implemented in the form of descriptor rings, and they allow FIFO operations with bulk/burst queueing/dequeueing. The descriptors are the objects that hold the pointers to the *rte_mbuf* structures where the packets are stored.

The main problem with the existing fast I/O platforms is that the packet processing functionality needs to be written from the scratch, which is time-consuming and error-prone. Luckily, the DPDK framework offers many libraries that can be used to quickly implement desired network applications. For example, the DPDK packet framework allows definition of completely custom packet processing, which is implemented by connecting standard blocks such as ports (hardware rings, software rings, etc.) and lookup tables (Exact Matching (EM), Longest Prefix Matching (LPM), Access-Control Lists (ACL) etc.). The *rte_tables* library helps users to create efficient lookup tables for batch packet processing. The library allows the user to specify the addition or removal of the MPLS header to the packet, which can be used to implement the ingress and egress MPLS functionalities.

The additional advantage of the DPDK framework is the richness of its sample applications which provide insight about the various functionalities that can be implemented. For example, application *l3fwd* is used to perform the high-speed IPv4/IPv6 packet forwarding. The IP processing is parallelized through the usage of multiple lcores. Each lcore has its own set of input and output queues assigned to it. Lcore fetches the packets in the batch from its RX queues, process them, and sends them to the appropriate TX queues. The forwarding decision is based on the packet content. For the IPv4 packets, it is the destination IPv4 address, upon which the LPM is applied. The LPM is performed via the tables designed for fast LPM lookup (*rte_tables* library). Result of the lookup process is the output interface where the packet should be sent.

III. Implementation Details

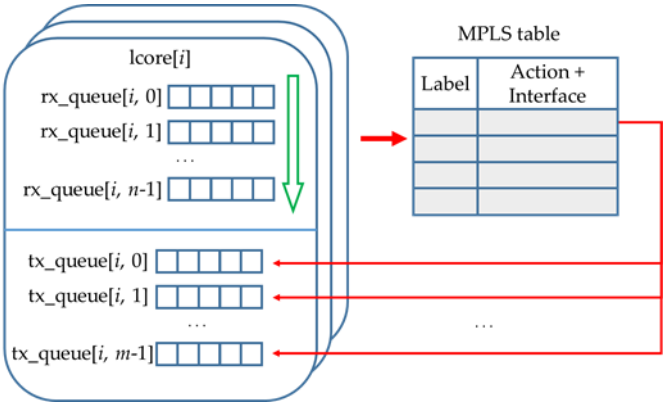

Fig. 1. Lcore RX/TX queues assignment and MPLS processing diagram

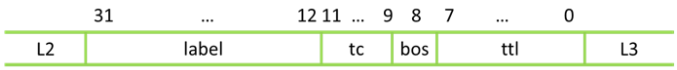
The MPLS forwarding application is partially based on the *l3fwd* application program code. Function of the main thread is similar. It parses the user arguments, allocates the resources, configures the ports, queues and lcores and checks whether the configuration is valid. At the end, the main thread launches all the lcores, which are performing the MPLS specific processing.

In the MPLS forwarding application, the number of RX queues per port is defined by the user. Users can specify the arbitrary number of queues per port, and to assign these queues to the specific lcore for processing. The number of TX queues at each port is equal to the number of active lcores, one TX queue per each lcore. In Fig. 1, we can see that each $lcore[i]$ $(i = 0,1,...,num\_lcores-1)$, has multiple RX/TX queues associated with it. The number of RX queues, n, is given via the user configuration, while the number of TX queues is $m = num\_lcores$. The packets are read from all the RX queues in a round-robin fashion. Afterwards, the packet processing is applied to all of the received packets. In this application, only the MPLS packets are processed, while the other packets are discarded. MPLS packets are modified and forwarded to the output TX queues.

Packet reads and packet writes are all performed in a burst mode. The burst size can be configurable, with the default value of 32. The packets are stored in the intermediate buffers until the specified number of packets is available for one port. If the number of packets available after some fixed period of time is less than this specified value, the packets are sent to their output. This is done in order to have latency limited.



MPLS lookup table		
Label	Action	Data
0x00000 ... 0xFFFFF	PUSH | POP | Label Switch + TTL Dec	New Label(s) + Output Interface

Fig. 2. MPLS header and MPLS lookup table

MPLS protocol has a 32-bit long header, inserted between L2 and L3 headers. Its fields are MPLS label, Traffic Class (TC), Bottom of Stack (BOS) and Time to Live (TTL). MPLS label is used to forward the traffic in the MPLS network instead of IPv4/IPv6. Its main advantages is that it is only 20 bits long, allowing simple lookup procedure. TC is used for fulfilling of the QoS requirements. The TTL field is similar to the TTL from IPv4 protocol. In fact, it inherits the TTL value from the IPv4 at the ingress router, and it is used to modify the TTL value of the IPv4 at the egress router. The BOS field indicates the last MPLS header in the case where multiple MPLS headers may exist.

The MPLS table is indexed by the MPLS label. The lookup result is the action and the output interface where the packet should be sent. The most common action is the MPLS label switching, where the old label is replaced with the new label. In this case, the lookup result also provides the new MPLS label. Other possible actions are addition/deletion of the MPLS header (push/pop), as well as the packet dropping.

In our implementation, we have created the MPLS table as an array of 2^{20} entries. For the LSRs, we have implemented only the label switching action. The lookup result has additional information about the neighbor destination MAC address, as we do not have Address Resolution Protocol (ARP) implemented. The label switching functionality could have been implemented using direct access *rte_tables* also. However, this is impractical since it imposes additional processing overhead compared to the simple array indexing.

The main MPLS function was optimized to achieve as high processing speed as possible. Some of the techniques, like function inlining, were necessary to avoid the costly function calls. Parsing of the header requires usage of the standard logical operations, like shifting, logical AND and logical OR operations. However, we have noticed some issues with the code where too many logical operations are called at the same time. If we were about to split the header into the 4 different fields, as in Fig. 2, and later reassemble it, the lower performance would be achieved, probably due to the processor resource starvation. However, we have split the MPLS header into only two distinct parts, the MPLS label part and the remaining part, and the performance was couple of Mpps better.

IV. Testing Environment

Testing environment setup is shown in Fig. 3. We have two workstations that are connected via 10G Ethernet copper cables. The first workstation is used as a packet generator. It generates packets on two available ports, with the speeds of 10 Gbit/s per port. This machine also receives and measures the forwarded traffic. The packets are generated using the DPDK Pktgen application [14], version 3.5.9.

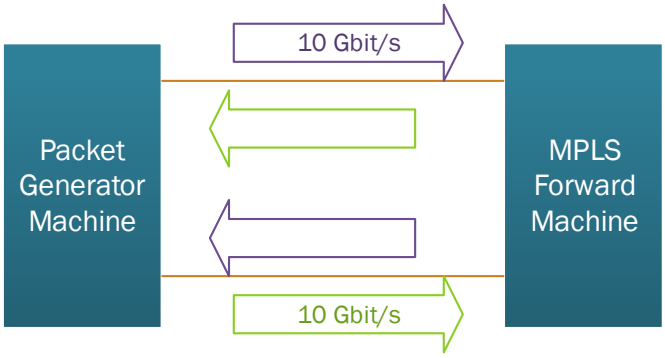


Fig. 3. Testing setup

The second workstation is used as a test machine where the MPLS forwarding application is installed. The application receives the packets, performs the MPLS lookup, and forwards the traffic back to the packet generator. The MPLS lookup table is set to forward the traffic from the port 0 to the port 1 and vice-versa. The application is based on the DPDK version 18.05.1. Characteristics of the MPLS forwarding

machine are summarized in Table I.

TABLE I
TESTING MACHINE SPECIFICATION

Processor	Intel Core i7-3770K CPU L1d/i cache: 32K L2 cache: 256K L3 cache: 8192K Frequency: 3.50GHz
RAM Memory	2 x 8 GB DDR3 Frequency: 1600 MHz
Network Interface Card	Intel Ethernet X710-DA4 Quad Port, Driver: i40e
Operating System	CentOS Linux 7, x86_64 Kernel: 3.10.0-862

V. RESULTS

We have measured the packet forwarding rates of the MPLS application for different packet sizes in the range of 64 B to 1522 B, and 1024 descriptors per queue by default. We have generated the 20 Gbit/s traffic using the DPDK pktgen. Packet rates are dependent on the packet size and can be calculated by the formula:

$$pkt\_rate = bit\_rate/(8\cdot(pkt\_size+20)) \qquad (1)$$

MPLS packet processing rates are shown in Fig. 4. From the graph, we can see that the forwarded traffic is the same as the generated traffic, except for the shortest packets. We have achieved the forwarding rates of 26.22 Mpps (17.76 Gbit/s) for 64 B packets, which is 3.54 Mpps lower than the maximal possible value of 29.76 Mpps.

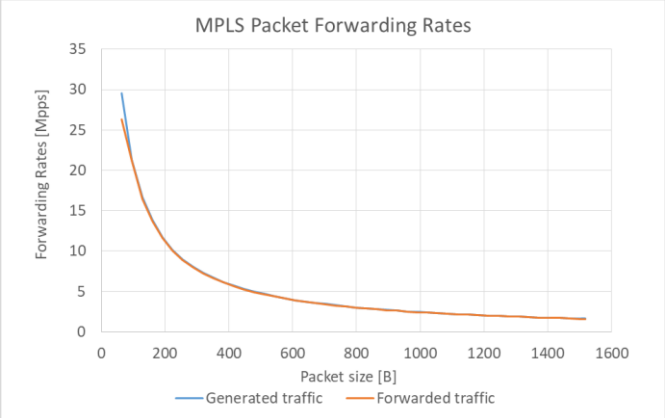

Fig. 4. MPLS packet forwarding rates for different packet sizes

We have also wanted to measure the influence of the number of RX/TX descriptors on the forwarding rates. For that purpose, we have measured the forwarding rates for the 64 B packets, and different number of descriptors per RX/TX queue. The measurements have been performed for the case where two ports are used, with one RX queue and one TX queue per each (port, lcore) pair. The results are shown in Fig. 5. The peak performance is around 27.45 Mpps for 256 RX/TX descriptors per queue. When the number of descriptors is small, fewer packets are available for processing which is the limiting factor. On the contrary, if the number of descriptors is too high, we will experience another performance drop. The reason is the suboptimal L1 cache usage.

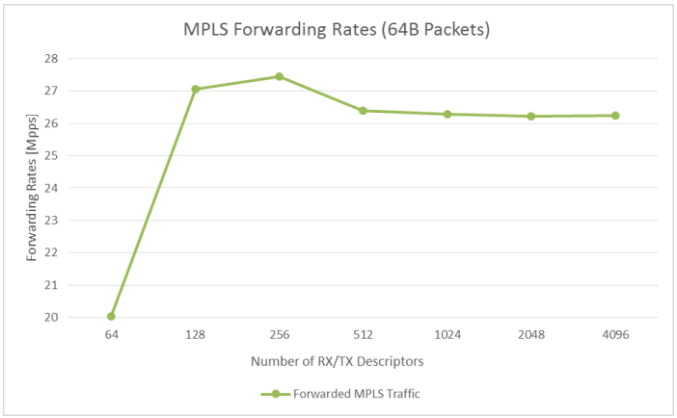

Fig. 5. MPLS packet forwarding rates for different number of descriptors per RX/TX queue and 64 B size packets

In the previous test, we have seen that the best performance is achieved for 256 descriptors per queue. However, this value can vary depending on the number of queues used and the cache memory size. Thus, it is best to start from the default value of 1024 first, and, afterwards, to fine tune the performance. It is necessary to pinpoint that we have used the same value for the number of RX and TX descriptors. However, in reality, these values be independently set.

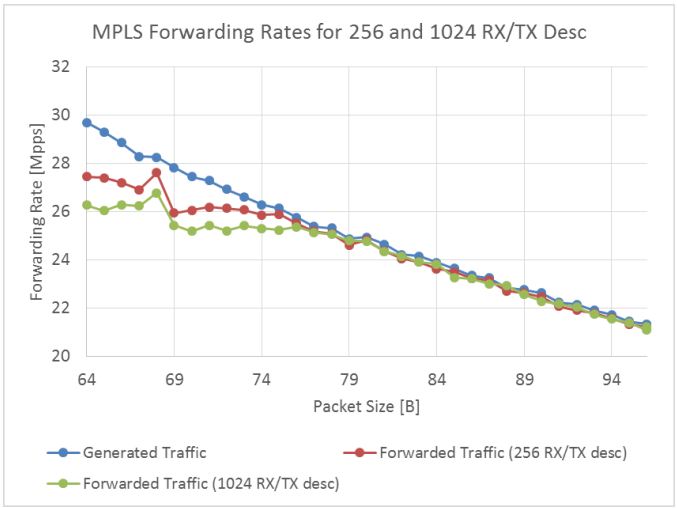

Fig. 6. MPLS packet forwarding rates for packets sizes in range [64B, 96B] and different number of descriptors (256 and 1024)

In Fig. 6, we can see the difference in the forwarding rates for the case where we have used optimal (256 RX/TX

descriptors) and the default value (1024 RX/TX descriptors) for different packets sizes. Due to clarity, we have only performed measurements for the packets sizes between 64 B and 96 B. Indeed, as we can see from the Fig. 6, for the packets longer than 77 B there is no huge difference in the performance between generated and forwarded traffic. The performance difference can vary up to 1 Mpps, depending on the packet size. We can also see the performance drop when increasing the packet size from 68 B to 69 B. This is because the packets become longer than the cache line size of 64 B (the last 4 bytes of the packet belong to the Ethernet trailer CRC, and these are stripped at the NIC level).

Currently obtained results are much better in comparison to our previous work. In [13], we have measured the performance of single-threaded MPLS application implemented using the netmap framework. For that application we have achieved the performance of around 8 Mpps on FreeBSD operating system using a single port. Our current implementation achieves nearly the maximal packet rates when only one port is used, which is 1.85 times better. In [12], we have parallelized the IPv4 lookup procedure using OpenMP and netmap. In that paper, we have reached the speeds of 25.26 Mpps for two ports and 64 flows per port. Our current MPLS implementation is 2.19 Mpps better even though only one flow per port is used. Unfortunately, in comparison to the *l3fwd* DPDK application, MPLS forward performance is slightly lower. The *l3fwd* application forwards nearly all of the generated traffic, approaching the maximal value of 29.76 Mpps.

VI. Conclusion

The MPLS protocol has important properties that allow better throughput, resiliency and security in the networks. Due to the fact that the lookup procedure is simplified, and that MPLS can support traffic engineering, it is essential protocol for the implementation of software routers which have limited packet processing rates. Fast I/O frameworks allow higher packet processing rates compared to the standard Linux kernel protocol stack. DPDK framework is a good fast I/O candidate, not only because it allows high throughputs, but because it is open source project with lots of sample applications and libraries to help with the implementation of network applications.

In this paper, we have implemented the MPLS label switching functionality for the MPLS LSR software routers using DPDK framework. Our application achieves the packet rates of 27.45 Mpps for the shortest 64 B packets when two ports are used. We have examined the performance variation when different number of RX/TX descriptors is used, and concluded that there is a tradeoff between optimal cache usage and available number of processing slots.

In the future work, we plan to implement and measure the performance of ingress and egress MPLS routers. We will also try to optimize the MPLS forward performance to be comparable with the *l3fwd* application. Additionally, we will try larger testing setup with more NICs and workstations.

Integration of the NETCONF Protocol in the Internet of Things by means of RESTful Web Services

Dalibor Đumić, Sretenka Došlić, Marija Antić and Boško Milić

***Abstract*— Herein a new network management protocol called Network Configuration Protocol (NETCONF) will be introduced through an overview and empirical study. The features and capabilities of the NETCONF are a document-oriented approach based on Extensible Markup Language (XML) and the challenge will be an integration of the NETCONF capabilities in the Internet of Things (IoT) using REpresentational State Transfer web services (RESTful). In the end, the goal is to implement this integration through building a home automation server based on any single board computer supporting Linux operating system (OS) and RESTful web application as the client. The web application shall communicate with the server through the NETCONF protocol and allow a user to control devices in his home. In the end, the benefits of applying such these technologies in the home automation or domotics will be discussed and concluded.**

***Index Terms*—NETCONF, Internet of Things, REST, IHGNM, home automation, domotics**

I. Introduction

There is a number of heterogeneous devices present in-home network which is expected to be connected. Here, devices are based on different hardware platforms, controller services are also of a different nature, the software components that enable network access on them are also of different nature for each device. For example, health and lifestyle wearable Internet of Things (IoT) devices like a smartwatch, wristband have different capability in terms of memory usage, power consumption, processing speed as compared to smart home appliances like a washing machine.

IoT devices can be generally classified based on their key characteristics like communication pattern, memory usage, data processing capability, and power consumption. For example, devices like smart keys or a smart washing machine don't need to be connected always and are switched on to perform certain tasks when required; these devices consume less power for communication. This paper is focused on such low power or normally off devices in a home network as they need a gateway for effectively managing operations and communication with the Internet.

The paper is organized as follows. Section 2 addresses important background information on device management in the home automation system. In Section 3, the NETCONF protocol and its features are introduced. The proposed integration of the NETCONF protocol in the IoT is detailed in Section 4. Possible use cases are discussed in the Section 5. Finally, the lessons learned, and the main conclusions are addressed in Section 6.

II. Background

Particularly, there are two common approaches for managing devices in home automation system: simple network management and intelligent home gateway network management (IHGNM). Each of these approaches is as per the application. [1]

If the devices have enough resources that it supports a direct connection to the internet in a secure manner and does not support multiple device classes, the implementation is possible with a lightweight machine to machine (LWM2M). LWM2M is a remote device management standard. In this, IoT devices can be directly managed. This is an example of simple network management. [2]

In IHGNM architecture, multiple device classes from low resource constrained to high resource-constrained devices are considered. The proposed architecture monitors many heterogeneous devices in a home network. Here, IHGNM architecture for a high resource-constrained device in a home network is discussed.

III. Empirical Study of the NETCONF

A. NETCONF

The Network Configuration Protocol (NETCONF) is a network management protocol that can install, manipulate, and delete the configuration of the devices in the network. Its purpose is managing network devices, retrieving its configuration data, and uploading or manipulating new configuration data of the network devices. That means devices

Boško Milić is with the RT-RK Institute for Computer Based Systems, Patre 5, 78000 Banja Luka, Bosnia and Herzegovina (e-mail: Bosko.Milic@rt-rk.com).

on the network can take different states according to their configuration. [3]

Configuration datastores are used for switching between these states. A configuration datastore is the complete set of configuration information which is needed to change a device's state from its initial default state into a desired operational state. NETCONF supports multiple configuration datastores (candidate, running, startup) as well as event notification feature. [4]

- "running" - the currently active configuration of a device and it is always present.
- "startup" - the configuration that will be used during the next startup.
- "candidate" - a configuration that may become a "running" configuration through an explicit commit.

Manipulating device configuration is possible using NETCONF operations. Operations are invoked as Remote Procedure Calls (RPCs) from the client to the server. Some minor operations are:

- "commit" - commits the "candidate" configuration to "running",
- "copy-config" - copy one configuration datastore to another,
- "edit-config" - changes the contents of a configuration database,
- "get-config" - retrieves configuration datastore,
- "lock" - prevent changes to a datastore from another party, and
- "unlock" - releases lock on a datastore. [5]

Configuration data stored on devices and the protocol messages between devices are encoded in Extensible Markup Language (XML) on both client and server side. The client can be a script or application typically running as part of a network manager. The server is typically a network device.

There is a rule that a device on the network must support at least one NETCONF session. The main NETCONF message exchange between client and server in a single NETCONF session is illustrated in Fig. 1.

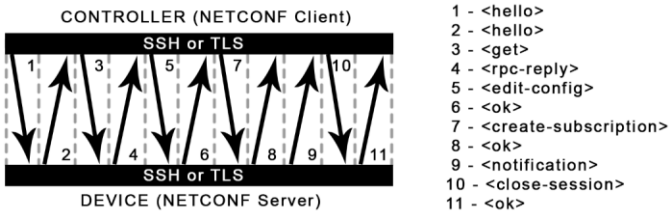

Fig. 1. NETCONF messages

The information that can be retrieved from the server is separated into two classes: configuration data and state data. Configuration data is the set of writable data that is needed to transform a system from its initial default state into its current state. State data is the additional data on a system that is not configuration data such as read-only status information and collected statistics. For specifying NETCONF data models and operations, the YANG data modeling language is used.

B. YANG

A YANG module defines a hierarchy of data that can be used for NETCONF-based operations, including configuration data, state data, RPCs, and notifications. This allows a complete description of all data sent between both NETCONF client and server side. Some of YANG statements are previewed in Table I. [5][6]

TABLE I
YANG STATEMENTS

Statements	Description
augment	Extends existing data hierarchies
choice	Defines mutually exclusive alternatives
container	Defines a layer of the data hierarchy
extension	Allows new statements to be added to YANG
feature	Indicates parts of the model are optional
grouping	Groups data definitions into reusable sets
key	Defines the key leafs for lists
leaf	Defines a leaf node in the data hierarchy
leaf-list	A leaf node that can appear multiple times
list	A hierarchy that can appear multiple times
notification	Defines notification
rpc	Defines input and output parameters for an RPC
typedef	Defines a new type
uses	Incorporates the contents of a "grouping"

YANG modules can be translated into an equivalent XML syntax called YANG Independent Notation (YIN), allowing applications using XML parsers and Extensible Stylesheet Language Transformations (XSLT) scripts to operate on the models. YANG defines a set of built-in types and has a type mechanism through which additional types may be defined. Derived types can restrict their base type's set of valid values using mechanisms like range or pattern restrictions that can be enforced by clients or servers. That means that the modeler can add constraints to the data the model to prevent impossible or illogical data. [6]

These constraints give clients information about the data being sent from the device and also allow the client to know as much as possible about the data the device will accept so

the client can send correct data. Table II briefly describes some other common YANG constraints:

TABLE II
YANG STATEMENTS

Statements	Description
length	Limits the length of string
mandatory	Requires the node appear
max-elements	Limits the number of instances in list
min-element	Limits the number of instances in list
must	XPath expression must be true
pattern	Regular expression must be satisfied
range	Value must appear in range
reference	Value must appear elsewhere in the data
unique	Value must be unique within the data
when	Node is only present when XPath expression is true

The module, which is the base unit of definition in YANG, defines a single data model. It contains three types of statements: module-header statements, revision statements, and definition statements. The module header statements describe the module and give information about the module itself. The revision statements give information about the history of the module and the definition statements are the body of the module where the data model is defined. [5] To use YANG, YANG modules must be defined to model the specific problem domain. These modules are then loaded, compiled, or coded into the server. [4] Finally, a NETCONF server may implement any number of modules. [5]

IV. PROPOSED METHODOLOGY

After the empirical study of the NETCONF protocol and retrieving its features, the proposed integration of the NETCONF protocol in the Internet of Things should be divided into two parts: server side and client side, as it is shown in following Fig. 2.

Fig. 2. An overview of the integration of the NETCONF protocol in the Internet of Things

A. Server Side

Since the main goal is to implement this integration in home automation, an ideal server for this case is shown in Fig. 3.

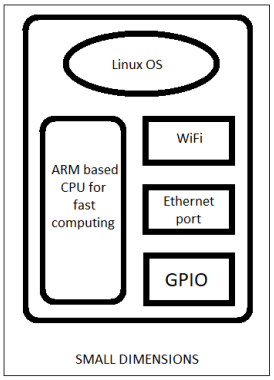

Fig. 3. An overview of ideal single board computer

It should be a single board computer which possesses the following important characteristics:

- small physical dimensions,
- able to boot Linux Operating System,
- has General Purpose Input Output (GPIO) pins for interfacing with the sensors and devices,
- has Ethernet port and/or WiFi module, and
- CPU based on ARM for fast computing.

Great match for the single board with these following characteristics is Raspberry Pi 3 B+, which is based on 1.4GHz 64-bit quad-core ARM Cortex-A53 processor. [7]

The good thing about Raspberry Pi is that it has the GPIO module which can be used through several programming languages such as C, C#, Python, Java, etc. The fact is that the integration will be implemented by using Python programming language and it makes Raspberry Pi a perfect match. To build a server, it is necessary to install Netopeer2, a set of tools implementing network configuration based on the NETCONF protocol. [8] Each room in a home would have installed sensors and relays for controlling devices. A server would be connected via appropriate connection lines to these rooms as it is shown in following Fig. 4.

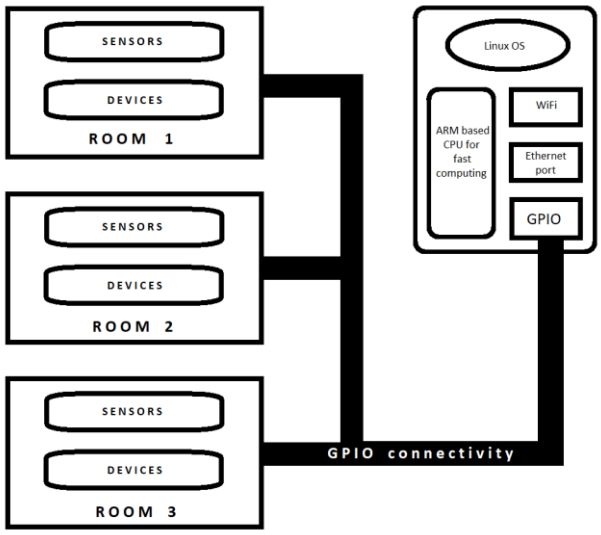

Fig. 4. GPIO connectivity of home rooms and server side

For each room, a custom YANG module should be created, and each custom YANG module should have data such as temperature, humidity, open or closed status, turned off or turned on status, etc. The structure of the simplest custom YANG module for a room is shown in the section "Appendix". On that way, the server can easily manage the information related to the sensors and relays in the home through these custom YANG modules. [9]

B. Client Side

On the client side, any device which supports the NETCONF protocol can communicate with the server. However, the challenge is to develop an application by means of RESTful services. It should send the RPC commands such as "edit-config" or "get-config" directly to the NETCONF server in order to retrieve information about rooms in the user's home. Finally, its interface must be user-friendly and rich with data charts, data graphs, toggle buttons, etc.

The very first step is to develop a script which shall "talk" with the NETCONF server. Thanks to enormous possibilities of the Python programming language, it is possible to communicate with the server via the NETCONF protocol by using ncclient library. The ncclient library facilitates client-side scripting and application development around the NETCONF protocol. [10]

The next step is to develop a web application and merge it with the script based on ncclient library. There are many high-level Python web frameworks and one of them is Django. Django is specific because it encourages rapid development and clean, pragmatic design. [11] By combining Django and ncclient, a powerful user-friendly web application is created, and it will fulfill its main purpose – to collect all information about the conditions such as temperature and humidity in the rooms of the user's home and to control devices in the rooms of the user's home, all of it over the NETCONF protocol.

V. Potential Use Cases

Some of the application of the domotics based on the technologies in the proposed methodology will be discussed in the potential use cases.

A. Case I: Smart House

The domotics in smart houses would be focused on saving energy by turning the lights on to illuminate dark stairs and turning them off when nobody is around. It would also turn the lights on and off even when there is nobody at home, to simulate occupation, or automatically turning down air conditioning systems when the external temperature drops, controlling cameras and security devices, etc.

B. Case II: Smart Hospital

The automation of the healthcare sphere is one of the most urgent and, perhaps, the most difficult tasks in the world. The concept of smart hospitals will let people save time and take better care of them. Moreover, it will help doctors organize their schedules more effectively, making it possible to avoid long queues in hospitals while medical staff can manage their time easily.

C. Case III: Smart Hotels

In the hotel industry, the priority should be turning the hotels into a smart hotel, because it can significantly improve the customer experience, make life easier for staff, and save owners money. Using a smart room, guests are able to control the various components and get their room exactly how they like it. They also find it both faster and easier to obtain important information. In the end, creating a smart hotel can also reduce the number of operational costs.

VI. Conclusion

Through the empirical study of the NETCONF protocol, great capabilities of the NETCONF protocol are discovered. It allows us to have an unlimited number of YANG modules with different structures of the data. This characteristic of the NETCONF protocol is the main reason for using it in domotics.

The integration of the NETCONF protocol in the Internet of Things is not a challenge anymore. Thanks to the powerful Python Web framework and ncclient Python library, it is possible to develop a rich web application which can be outperformed on many devices such as single board computers, desktop computers, notebooks, and even the tablets.

Appendix

```

Comparison of RCIED Activation Responsive and Active Jamming Reliability

Mladen Mileusnić, Predrag Petrović, Aleksandar Lebl and Branislav Pavić

***Abstract*— In this paper we compared the time required for the successful jamming of remote controlled improvised explosive devices activation using active and responsive jamming methods. As a representative of active jamming method we analyzed jamming signal generation using frequency sweep, whereas for the analysis of the possible activating signal presence based on responsive jamming procedures we supposed Fast Fourier Transform (FFT) implementation. Taking into account the current technology state, it is proved that the time required to achieve the successful jamming relied on FFT analysis may be less than in the case of active sweep jamming. When very fast specialized processors are applied to FFT estimation with the highest clock speed, the required time to achieve effective jamming may be up to several tens of times less based on FFT detection for responsive jamming than in the case of active sweep jamming.**

***Index Terms*— active and responsive jamming; RCIED - remote controlled improvised explosive devices; frequency sweep; Fast Fourier Transform; jamming reliability.**

I. Introduction

THE common characteristic of all remote controlled improvised explosive devices (RCIED) is that they are activated by wirelessly transmitted messages. The results of RCIED activation message could be disasterous regarding people lives (VIP persons) and the equipments damages. All elements related to activation signal characteristics (signal power, frequency, implemented modulation method, message duration) are completely unknown. This fact produces great problems in the realization of RCIED activation jammers. Contributions [1] and [2] provide a general overview of jammers types, communications jamming requirements and their efficiency analysis. Modern communications jamming principles and techniques may be found in [3].

There are two basic approaches to the jammer implementation. The first one is active jamming, which consisted of continuous predefined jamming signals sending independently of the RCIED activating message characteristics. In this concept there are no „look through“ phases to detect the activation message existence and the jamming signal characteristics are selected in general using previous experience and expectations. The most important freely selected jamming signal parameter is the RF signal level. This level has to be as high as possible to successfully prevent activating message reception. Two key features which are not optimally chosen relate to continuous jamming regardless of RCIED activation message existence and the RF jamming signal level necessary for jamming successfulness due to the fact that the activation signal level is unknown.

The alternative approach to jammer implementation is responsive jamming concept. In this case the jamming signal characteristics can be optimized using look through intervals to detect the activation message existence and its level. That's why it is possible to send the jamming signal only during activation message presence and jamming signal level can be adjusted to the activation message level in order to successfully deny the threat. A wide range of active and responsive jammers may be found in [4]-[13].

It may be concluded from this short presentation of active and responsive jamming characteristics that active jamming is always successful, while responsive jamming efficiency depends on activation message detection reliability. The question is whether responsive jamming reliability may be greater than for active jamming. In this paper we compare the reliability of mostly implemented active jamming method – frequency sweep [14]-[18] to the reliability of a representative method for activating signal eventual presence detection in order to generate jamming signal according to the activation signal characteristics by implementation of Fast Fourier Transform (FFT) in the analysis [13].

The method for RCIED activation signal frequency spectrum estimation based on FFT analysis is presented in Section 2 with the emphasis on the required time for calculation. Section 3 is devoted to frequency sweep jamming and to determination of required time to realize one complete jamming cycle. In Section 4 jamming reliability on the basis of FFT analysis is compared to the frequency sweep jamming reliability, whereby two special purpose processors are considered for FFT calculation. Reliability estimation is based on the required time to allow successful jamming. Section 5 explains the influence of pipeline signal processing on the performances of responsive jammer. At the end, the paper conclusion is given in Section 6.

II. Signal Spectrum Estimation on the FFT Basis

FFT is the calculation procedure, which allows relatively fast estimation of discretized signal frequency spectrum. Starting from n time samples of analyzed signal, this procedure gives a snapshot of signal frequency spectrum also in n points, i.e. n spectrum lines are obtained. FFT is the optimum method taking into account the required number of

Aleksandar Lebl is with the Institute IRITEL, Batajnički put 23, 11080 Belgrade, Serbia (e-mail: lebl@iritel.com).

Branislav Pavić is with the Institute IRITEL, Batajnički put 23, 11080 Belgrade, Serbia (e-mail: bane@iritel.com).

mathematical operations for signal spectrum determination. There are $(n/2)\cdot log_2(n)$ complex multiplications and $n\cdot log_2(n)$ complex additions [19]. The limitation for n is that the condition $n=2^a$ must be satisfied, where a is the positive integer number. This is a significant saving in the number of mathematical operations and in the required calculation time comparing to the classical method of frequency spectrum estimation by Discrete Fourier Transform (DFT). Namely, it is necessary to perform n^2 complex multiplications and n^2-n complex additions to obtain n frequency spectrum components by DFT on the base of n time samples.

Let us suppose that f_s is the frequency of analyzed signal sampling. The sample acquisition time is then:

$$T = \frac{n}{f_s} \tag{1}$$

The frequency resolution on the base of sample acquisition time may be determined as:

$$df = \frac{1}{T} = \frac{f_s}{n} \tag{2}$$

Therefore, frequency resolution is improved when acquisition time is increased, i.e. the space between frequency spectral components of the analyzed signal is lower.

Constant advancements in processor realization technology and mathematical algorithm improvements are visible in two aspects of FFT calculation progress. On the one side the number of points in which frequency spectrum is determined is constantly increased, and on the other side the required FFT calculation time for some exactly determined number of frequency spectrum components is constantly decreased, chronologically, successively according to presentations in [20], [21], [19], [22]. We selected two approaches referenced in [19] and [22] due to very fast processing algorithms.

Data presented in [22] is related to the FFT calculation time as a function of the number of signal time samples implemented for FFT calculation, i.e. as a function of the obtained frequency components number in the analyzed spectrum. The presented data is for processor clock of 1GHz. It is further emphasized in [22] that improvement may be achieved by processor clock speed increase to 1.25GHz. Besides, it is stated in [23] that maximum processor clock frequency may be even 1.4GHz. On the base of these data, the FFT calculation time (T_{cal} in ms) is presented in Table I as a function of the number of points used in a calculation, for a processor clock of 1.25GHz and for 8 processor cores. The value of the constant K is 1024 in the first column of the Table I.

The time of FFT calculation (T_{cal} in μs) according to the data emphasized in [19] is presented in the Table II. The processor clock in this case may be in the range between 60MHz and 150MHz [24]. That's why data are presented for the mean processor frequency of 100MHz. FFT hardware accelerator (HWAFFT) is one of the parts in the processor implemented according to [19]. HWAFFT is intended for faster FFT calculation. Data in Table 2 are related to the case when HWAFFT is implemented. The number of points is relatively small (till 1024) where FFT is calculated comparing to the number of points, where FFT results are presented in Table I.

The total time, which is needed for signal analysis in a jammer (T_{an}) before (eventually) starting RCIED activation jamming signal emission, consists of three components: sample acquisition time (T), FFT calculation time (T_{cal}) and the time, which is necessary to compare obtained signal frequency components after FFT calculation (T_{comp}) in order to determine whether it is necessary to start jamming. When considering the last component (T_{comp}), there is not such a data in a literature, because calculation is very specific. For our analysis, we supposed that taking equal values of T_{cal} and T_{comp} is a quite good approximation, i.e.

$$T_{an} = T + T_{cal} + T_{comp} = \frac{n}{f_s} + 2\cdot T_{cal} \tag{3}$$

TABLE I
THE TIME OF FFT CALCULATION AS A FUNCTION OF THE NUMBER OF CALCULATION POINTS FOR THE PROCESSOR PRESENTED IN [22]

Number of points for FFT calculation	Calculation time T_{cal} [ms] (8 cores, 1.25GHz)
16K	0.1051

512	37.4
1024	73.15

III. ACTIVE JAMMING USING FREQUENCY SWEEP

Frequency sweep is often used method of active jamming. It is necessary to linearly change signal frequency step by step from its minimum value (*f1*) to the maximum one (*f2*) in order to realize a sweep. It is a readily implemented jamming method, because a significantly smaller power is necessary in relation to wideband jamming based on Additive White Gaussian Noise (*AWGN*) [16] - [18]. Linear frequency change of jamming signal frequency is practically approximated by a stepwise change, as it is presented in Fig. 1. There are two parameters, besides outmost sweep signal frequencies *f1* and

f2, which model signal frequency change: frequency change step (f_Δ) and each step time interval duration while the same signal frequency is generated (T_Δ).

The total step number in jamming realization may be represented by an equation:

$$N = \frac{f2 - f1}{f_\Delta} \tag{4}$$

while the duration of one total sweep cycle may be represented as:

$$T_{sw} = N \cdot T_\Delta = \frac{f2 - f1}{f_\Delta} \cdot T_\Delta \tag{5}$$

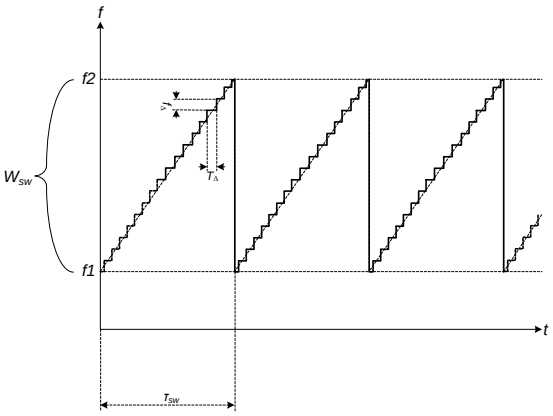

Fig. 1. Practical implementation of frequency sweep in the RCIED activation active jamming.

IV. Comparison of the Active and Responsive Jamming Reliability

The starting data in our analysis will be the required time to realize sweep jamming of RCIED activation signal under the condition that at least once jamming signal frequency and RCIED activation message frequency are approximately equal. After that we shall determine the total time from the beginning of the analyzed signal sample acquisition including FFT calculation time until the start of jamming signal emission on the detected RCIED activation signal frequency. In order to achieve comparison requirements of these two results, we shall suppose that the number of steps in sweep procedure (N) is equal to the number of points where the analyzed signal spectrum is estimated (n).

There is a number of D/A converters, which may be implemented for jamming signal generation. One typical example may be found in [25]. This D/A converter is used in our jammer solution [15]. It generates analog signal from the samples, whose maximum frequency is pretty high (f_s=3.5GHz), thus enabling maximum generated signal frequency f_g=1.4GHz.

Let us suppose that RCIED activation jamming is realized by jamming signal generation in a frequency band between *f1*=20MHz and *f2*≈1.33GHz. We shall further define the frequency change step f_Δ=20kHz, and the frequency sweep step duration T_Δ=200ns (very short time, a greater time is used in a practical realization - T_Δ=1μs or more [15]). On the base of (4) we obtain the number of steps in a sweep procedure realization N=65536=64K, and on the base of (5) sweep procedure duration is T_{sw}≈13.1ms.

Let us now have a device for responsive jamming, which collects the analyzed signal samples (performs A/D conversion) at the same frequency f_s=3.5GHz as the frequency of samples for D/A converter [26]. Number of samples that need to be collected, and consequently obtained number of the analyzed signal discrete frequency components is the same as the number of sweep steps (n=65536=64K). In this way it is achieved that the accuracy of jamming signal frequency *df* according to (2) is the same as the step of sweep signal frequency change f_Δ according to (4). In the case of responsive jamming, the signal sample acquisition time from (1) will be T≈18.7μs, while on the basis of Table 1 the FFT calculation time is T_{cal}=251.7μs. According to our adopted approximation it is also T_{comp}=251.7μs. Taking into account these three values, the total analysis time on the basis of (3) is T_{an}=522.1μs.

Comparing two time intervals which are the main indicators of active and responsive jamming reliability (T_{sw} and T_{an}), it is concluded that responsive jamming on the basis of FFT implementation is significantly more reliable (in our example ≈25 times) than active jamming by frequency sweep. One additional element which is an advantage of responsive jamming is the fact that after the analysis process (T_{an}) jamming may be performed only on the detected activation signal frequency with no time limit. In the case of active jamming, signal frequency is only during a short time period T_Δ approximately equal to the activation signal frequency. Therefore, due to greater jamming time it is also higher the probability that jamming is successful when responsive jamming is implemented.

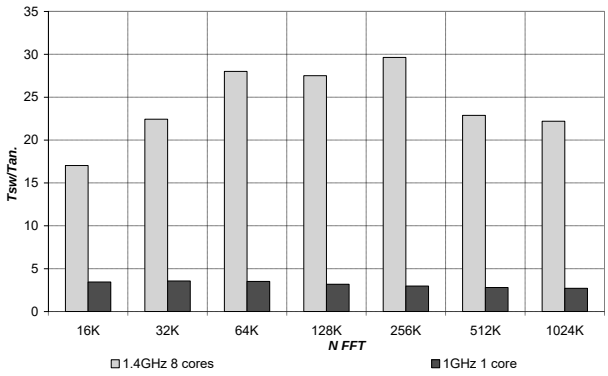

Fig. 2. The reliability of responsive jamming on the FFT basis according to [22] in relation to active frequency sweep jamming.

Fig. 2 presents the results of reliability comparison of responsive jamming based on FFT analysis according to data from [22] in relation to active jamming based on frequency sweep. When active jamming is considered, jamming time on each frequency is adopted to be 200ns. Two extreme cases are chosen for responsive jamming: a) the first one, which allows maximum analysis speed (maximum specified processor clock frequency 1.4GHz and maximum number of processor cores – 8) and b) the second one, which corresponds to the minimum

analysis speed (minimum processor clock frequency 1GHz and minimum number of processor cores – 1). The required number of processor cycles for FFT calculation as a function of the number of FFT points is taken according to Table 1 from [22]. After that, it is determined the necessary time for FFT analysis in some cases. The graph in Fig. 2 indicates greater reliability of responsive jamming on the base of FFT in relation to active jamming using frequency sweep in all jamming conditions, because the calculated relation of jamming reliability is always between two extreme cases presented in Fig. 2 (i.e. this relation is always greater than 1).

Fig. 3 presents the results of reliability comparison of responsive jamming based on FFT analysis according to data from [19] in relation to active jamming based on frequency sweep. The processor implemented for FFT calculation operates on lower frequencies (between 60MHz and 150MHz) [24] than in the example from Fig. 2. That's why it is adopted that analyzed signal sampling is realized on a significantly lower frequency (800MHz) than in the example in Fig. 2. This further means that jamming is realized in this case for lower frequencies (till 320MHz).

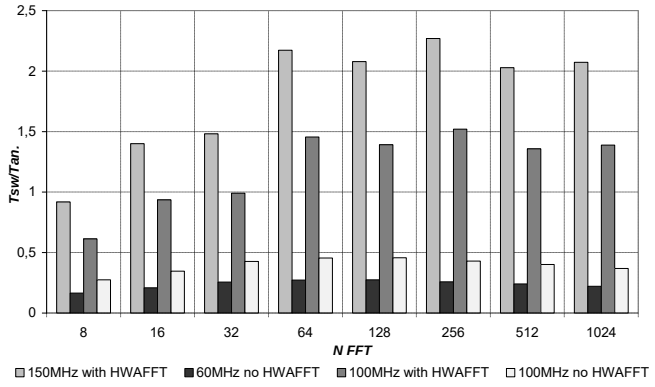

Fig. 3. The reliability of responsive jamming on the FFT basis according to [19] in relation to active frequency sweep jamming.

The results in Fig. 3 are presented separately in the case that HWAFFT is used for an analysis and when it is avoided. The maximum processing rate in this case is achieved if HWAFFT is used together with maximum processor clock frequency (150MHz), while the minimum processing rate is if HWAFFT is not used and the processor clock frequency is minimum (60MHz). These results are presented by first two vertical graphs for each number of frequencies in FFT analysis. Besides these two graphs, the results for mean processor clock frequency (100MHz) are presented when HWAFFT is used and when it is not used. The required number of processor cycles to calculate FFT for some number of points in FFT analysis is determined on the base of Table 3, i.e. Table 4 from [19].

Using the analysis the results in Fig. 3 it can be concluded that the application of HWAFFT allows also in this case that responsive jamming using FFT may be more reliable than the active jamming by frequency sweep (except for the smallest number of analyzed frequencies – 8, which is unlikely to occur in practice). On the contrary, if HWAFFT is not used, responsive jamming reliability using FFT becomes lower than the reliability of frequency sweep jamming (because the relation $T_{sw}/T_{an}<1$). For the mean processor clock frequency (100MHz) and with the HWAFFT implementation for the smaller number of points in the analysis, frequency sweep implementation is more reliable, while for the greater number of points the analysis on the base of FFT is better.

V. Influence of Pipeline Signal Processing

There is one additional possibility to improve performance of responsive jammer, which is realized by FFT implementation [27]. This possibility is related to pipeline processing. The features of such processing may be explained by the illustration shown in Fig. 4.

The time intervals reserved for signal samples collection, signal processing using FFT and decision making on the base of calculated FFT values are presented by different hatching in Fig. 4. In "normal" processing mode (row N_1) the result of decision making is available during time intervals T_3 and T_6. Hardware components used for sample collection are only active during time intervals T_1 and T_4. FFT is calculated only during time intervals T_2 and T_5, while decision is made only during T_3 and T_6. Roughly speaking, all dedicated hardware parts are active approximately one third of time.

Pipeline signal processing contributes to better hardware utilization and in the same time to achieve more reliable results, because they are more often available. These can be explained by rows N_2, N_3 and N_4 in Fig. 4.

The characteristic of pipeline processing is that sample collection, FFT analysis and decision making are realized in each time interval. For the samples collected during T_1 decision is available in time interval T_3 (row N_2). Further, for the samples collected during T_2 decision is available in time interval T_4 (row N_3), and so on. In this way the results of an analysis are available three times more often, while using approximately the same hardware.

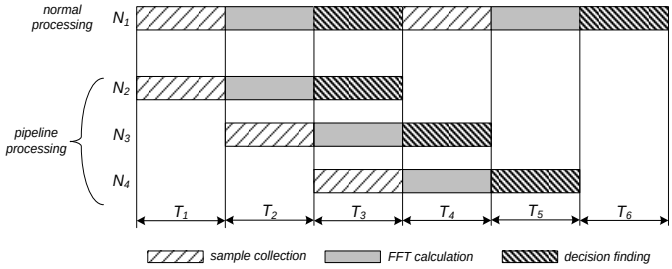

Fig. 4. Illustration of pipeline signal processing for responsive jamming realization.

VI. Conclusions

The results of the calculation presented in this paper have proved that responsive jamming may be more reliable than active jamming. The required time for secure jamming signal generation on the frequency of RCIED activation message is analyzed as a criterion of jamming reliability. If active jamming is realized by generation of frequency sweep signal, jamming is considered to be successful in the case that

complete cycle of frequency change from the lowest frequency towards the highest one is passed. Process of responsive jamming by FFT implementation includes period of signal sample acquisition for the future analysis, the time required for FFT calculation and the time of calculated frequencies comparison in order to make a decision about (eventual) jamming signal generation. As the result of complete analysis based on FFT, the frequency of RCIED activation signal is obtained, and jamming on the exactly determined frequency may be initiated. The results are compared for two processors, which are specialized for FFT calculation. One of these two processors provide that responsive jamming based on FFT implementation is more reliable than active jamming using frequency sweep. In this case analysis rate is several times, and even up to several tens of times greater when FFT is implemented in the analysis in relation to the frequency sweep rate. For the second analyzed processor reliability of responsive jamming depends on processor hardware characteristics such as the processor clock frequency and whether hardware accelerator (HWAFFT) is applied. If HWAFFT is included in the analysis with the higher processor clock frequency, jamming based on FFT analysis is certainly more reliable. On the contrary, if HWAFFT is not used with the lower processor clock frequency, the speed of FFT analysis may not approach jamming speed realized by frequency sweep.

It can be summarized that the results of comparative analysis presented in this paper prove that at up-to-date technological development level, RCIED activation responsive jamming may be very reliable and very often even more reliable than active jamming.

ACKNOWLEDGMENT

The paper is written in the framework of project TR 32051, which is cofinanced by Ministry of Education, Science and Technological Development of Republic of Serbia, 2011-2019.

Direct Ranging and Direction of Arrival Estimation of Non-cooperative Radio Transmitters

Dragan D. Golubović, Nenad J. Vukmirović and Miljko M. Erić

***Abstract*— A MUSIC type algorithm for direct one-step ranging and direction of arrival estimation of non-cooperative narrowband radio transmitters with antenna array is proposed. The method is applicable for far field or near field, single or multi-user non-cooperative signal scenario with planar or spherical waves on antenna array. Antenna array can be with distributed antennas but also it can be classical antenna array with co-located antennas on small distance. The proposed algorithm is suitable for application in massive MIMO systems for 5G. Properties and performance of the proposed algorithm are illustrated and evaluated by simulations. To reduce the computational cost of the algorithm, and provide valid results of simulation, adaptive searching grid in calculation of cost function is applied.**

***Index Terms*— direct localization, direct direction-of-arrival and range estimation, source localization, adaptive searching grid, massive MIMO, 5G.**

I. Introduction

The focus of this paper is joint one-step ranging and Direction of Arrival (DOA) estimation of non-cooperative narrowband radio transmitters with an antenna array. This joint estimation problem is equivalent to location estimation.

Localization in cellular wireless systems, such as in massive MIMO for 5G, is up-to-date research topic. There are two main groups of localization methods: classical widely investigated two-step localization methods (such as RSS, TDOA, DOA) and one-step (direct) position determination (position estimation methods). A method for direct position determination (direct position estimation) proposed in [1,2] was developed for a system with distributed antenna subarrays applied in a spatial semi-coherent signal scenario. A method for direct localization in massive MIMO system with distributed antennas is proposed in [3]. The method for direct position estimation with a millimeter-wave massive MIMO system based on distributed steerable phased antenna arrays is proposed in [4]. The method for joint range/DOA estimation of radio transmitters was a subject of papers [5,6]. In the paper [7] the authors proposed a method for joint range and azimuth estimation of acoustic signals with microphone arrays. In this paper, the system and signal model proposed in [7] for acoustic signals on microphone array are generalized to the radio signals on an antenna array. An antenna array can be classical with co-located antennas on small distance (around half of carrier wavelength), or with distributed antennas. The direction of arrival of the signal at the antenna array is defined in relation to the reference antenna, so signal model can be applied both for planar and spherical waves. There is no limitation of the antenna geometry (it can be with collocated or distributed antennas). Some of antennas can be grouped in distributed antenna subarrays. Not every antenna array geometry is equally good for joint ranging and DOA estimation. It is also assumed that signal scenario is fully spatially coherent (Line of Sight –LOS).

Based on the signal model at the antenna array a MUSIC type algorithm for 2D joint (direct) ranging and direction of arrival estimation of non-cooperative narrowband radio transmitters is proposed.

The proposed algorithm is numerically complex and demanding. We made some modifications and developed an estimation algorithm with less computation than MUSIC width a fixed searching grid. This algorithm is with a variable grid depending on the distance. This searching grid is adaptive and the main goal of this paper is to show and explain the performance of the proposed algorithm analyzing the RMSE of the range and azimuth depending on the distance from the reference origin. The performance depends on the signal-to-noise ratio (SNR) and the comparison for a different SNR values at the antenna array was shown. Using proposed algorithm it is possible to achieve the accuracy of 10^{-2}m for distance estimation and the accuracy of 10^{-3} degrees for azimuth estimation. We showed also the RMSE of the range and azimuth for different scenarios, where a signal source is inside the antenna array, where it is close to the antenna array and where it is far away from the antenna array. The first scenario illustrates the problem of ambiguity and is interesting for application in distributed massive MIMO systems, others are interesting from the aspect of the massive MIMO system. In the last section, we present the simulation results which illustrate properties and performance of the proposed algorithm.

II. Problem Formulation

In this part, a mathematical model and problem formulation are discussed. It will be assumed that the signal arriving at antenna array is narrowband.

The antenna array receives the radio signals (in the

Miljko. M. Erić is with University of Belgrade, School of Electrical Engineering, Bulevar Kralja Aleksandra 73, 11020, Belgrade, Serbia (e-mail: miljko.eric@etf.rs).

mathematical model their number is denoted by K), and the spatial sampling of the radio signal is performed. The number of spatial samples is determined by the number of antennas ($L > K$). It is assumed that the antenna array consists of L antennas arbitrarily located in space at the locations defined by vector $\mathbf{p}_i$, where i=1, 2…L. For simplicity, we suppose that antennas have identical omnidirectional characteristics. The origin of the coordinate system is in the center of the array. Fig. 1 shows the geometrical model of the system.

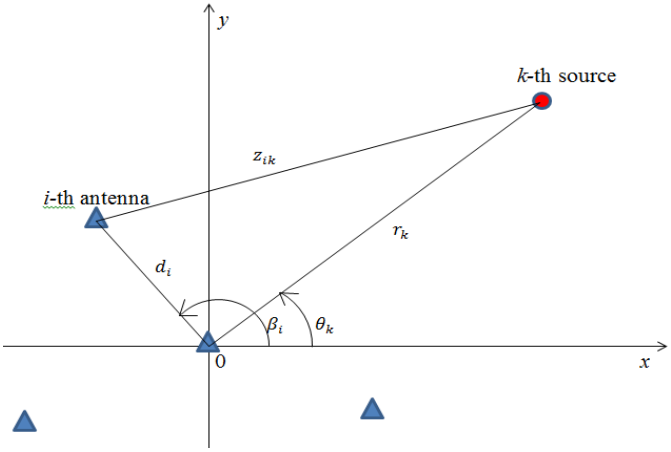

Fig. 1. Proposed geometrical 2D model of the system.

In this model, d_i indicates the distance of the i-th antenna from the reference origin, r_k is the distance of the k-th source from the reference origin, and z_{ik} is the distance between the i-th antenna and the k-th source. θ_k is azimuth of arrival of the k-th signal and β_i is the angle between x-axis and i-th antenna direction. The position of the i-th antenna in the antenna array can be expressed as:

$$\mathbf{p}_i = [p_{ix} \quad p_{iy} \quad p_{iz}]^T . \tag{1}$$

In this relation, p_{lx} , p_{ly} and p_{lz} are x, y, and z coordinates of the i-th antenna respectively. Because only a 2D case was analyzed, for the purpose of the analysis in this paper, z-coordinates will always be equal to zero, both for antennas and signal sources locations. Since the antenna array consists of L antennas, the matrix $\mathbf{p}$ with antenna positions has the form:

$$\mathbf{p} = \begin{bmatrix} p_{1x} & p_{1y} & p_{1z} \\ \vdots & \dots & \vdots \\ p_{Lx} & p_{Ly} & p_{Lz} \end{bmatrix} . \tag{2}$$

d_i is calculated as:

$$d_i = \sqrt{p_{ix}^2 + p_{iy}^2} . \tag{3}$$

We also have:

$$z_{ik}^2 = r_k^2 + d_i^2 - 2 r_k d_i \cos\theta_{ik} . \tag{4}$$

Determining the location of the signal source is possible if we estimate the distance of the signal source from the reference origin, as well as the angle between this direction and the x-axis. Therefore, further analysis will be carried out using radial coordinates (r_k, θ_k) for the signal source location, and (d_i, β_i) for the location of i-th antenna in the antenna array.

After defining all the necessary geometric parameters, a mathematical model of the summary signal can be formed at the i-th antenna:

$$x_i(m) = \sum_{k=1}^{K} v_i(r_k, \theta_k) s_k(m) + n_i(m) . \tag{5}$$

Where i is the antenna index (i=1,2,…L), M is the number of signal samples based on which the location will be estimated (m=0,1,…M-1), K is the number of signals, $s_k(m)$ is the m-th sample of the k-th signal, $n_i(m)$ is the m-th noise sample at the i-th antenna in the antenna array and $v_i(r_k, \theta_k)$ are responses of antenna elements to a signal from the desired source position. We assumed that only the additive white Gaussian noise is present [1].

Equation (5) can be formulated in matrix form using the following equations:

$$\mathbf{x}(\mathbf{r},\boldsymbol{\theta};m) = \sum_{k=1}^{K} \mathbf{v}(r_k, \theta_k) s_k(m) + \mathbf{n}(m) \tag{6}$$

$$\mathbf{x}(\mathbf{r},\boldsymbol{\theta};m) = \mathbf{V}(\mathbf{r},\boldsymbol{\theta})\mathbf{s}(m) + \mathbf{n}(m) \tag{7}$$

$$\mathbf{V}(\mathbf{r},\boldsymbol{\theta}) = \left[\mathbf{v}(r_1,\theta_1) \quad \mathbf{v}(r_2,\theta_2) \quad \cdots \quad \mathbf{v}(r_K,\theta_K)\right]. \tag{8}$$

In the above relations, $\mathbf{v}(r_k, \theta_k)$ represents the steering vector of the k-th source signal, where r_k and θ_k are the unknown parameters that will be estimated. By determining these two parameters, localization has been successfully performed for the k-th source. The dimension of the vector $\mathbf{v}(r_k, \theta_k)$ is Lx1, and the individual responses of the antenna elements to the signal from the desired direction are determined by the relation:

$$v_i(\theta_k, r_k) = \frac{c_{ik}}{z_{ik}} \exp(-j \frac{2\pi}{\lambda_c} z_{ik}) . \tag{9}$$

As can be seen from the observed relation, the distance z_{ik} enters the formulation of the steering vector, and therefore represents a very important parameter. λ_c is the carrier wavelength of the signal coming to the antenna array, and c_{ik} are the coefficients associated with the antenna gain. If it is assumed that omnidirectional antennas were used, these coefficients become independent of the antenna and the source, and it can be assumed that their value is equal to 1 for simpler analysis [4] [5].

Of particular importance is the process of normalization, because then the signal model can be generalized. If λ_c and λ_g are the carrier wavelength of the incoming signal and the wavelength of the upper limit frequency in the signal spectrum, respectively, then we can define a new parameter:

$$q_2 = \frac{f_c}{f_g} = \frac{\lambda_g}{\lambda_c} \tag{10}$$

This parameter also enters the formulation of the propagation vector:

$$v_i(\theta_k, r_k) = \frac{1}{z_{ik}} \exp(-j2\pi q_2 \cdot \frac{z_{ik}}{\lambda_g}). \tag{11}$$

This is a narrowband model but we can generalize it to also hold for broadband signals:

$$v_i(\theta_k, r_k, h) = \frac{1}{z_{ik}} \exp(-j2\pi(q_2 + q_1 \cdot \Omega_h) \cdot \frac{z_{ik}}{\lambda_g}). \tag{12}$$

Where $\Omega_h \in [-0.5, 0.5]$ and $q_1 = \Delta f_{BW} / f_g$, where Δf_{BW} denotes spectral bandwidth of the signal. It is very important to note that the mapping of radio signals from a reference point (reference antenna) to the antenna array will be done in the frequency domain, even in the case of a narrowband signal. By choosing the appropriate parameters, this model is generally applicable for both narrowband and broadband signals.

Based on this mathematical model, it is necessary to estimate unknown parameters, which are the range and the azimuth of the incoming signal source, respectively.

III. MUSIC TYPE ALGORITHM FOR DIRECT AZIMUTH AND RANGE ESTIMATION

The formulation of the MUSIC method is based on the specific properties of the correlation matrix of the signal incoming at the antenna array. Common to all high resolution methods for estimating the direction of arrival of the radio signal is the estimation of the covariance matrix using spatial samples of signals at the antennas and its interpretation on the subspace of the signal and the subspace of the noise. We are looking for eigenvalues and corresponding eigenvectors of this matrix. In the MUSIC method, the information about azimuth and elevation of incoming radio signals is obtained from the fact that the vectors propagating the current directions of arrival, are orthogonal to the eigenvectors, which correspond to the minimum eigenvalues of the covariance matrix. Appropriate eigenvectors borders with the subspace of the noise. Other eigenvectors, which correspond to the highest eigenvalues borders with the subspace of the signal.

In our model, it is necessary to modify the algorithm by not looking for azimuth and elevation, but azimuth and the range of the transmitter from the reference origin. When forming a criterion function, it is necessary to define the the noise subspace matrix as:

$$\mathbf{U}_N = [\mathbf{u}_{K+1} \quad \mathbf{u}_{K+2} \quad \cdots \quad \mathbf{u}_L] \tag{13}$$

Columns of this matrix are noise eigenvectors that correspond to the lowest eigenvalues. To determine the location of the radio signal source, a 2D criterion function of the MUSIC method is formed and defined as follows:

$$P(r, \theta) = \frac{1}{\mathbf{v}^H(r, \theta)\mathbf{U}_N\mathbf{U}_N^H\mathbf{v}(r, \theta)} \tag{14}$$

The arguments of the maximum of this criterion function (r_k, θ_k) are in fact estimations of unknown parameters and which will be determined (range and azimuth) using our approach.

This method is very accurate in determining locations, but it has great numerical complexity. It is based on a fixed searching grid, and the number of points where we calculate the criterion function rapidly grows when the resolution of the grid is increased. It is important to say that we choose azimuth and range resolutions separately. If the resolution is better, we need more time to estimate the location of the signal source. When the distance of the signal source is lower, estimation error will be smaller, and we can choose better resolution to locate the source without any problem. But for larger distances, it will be very inefficient to estimate the location using great resolution, because it takes a lot of time.

Therefore, we made some modifications end developed an adaptive estimation algorithm with less computation than MUSIC with a fixed searching grid.

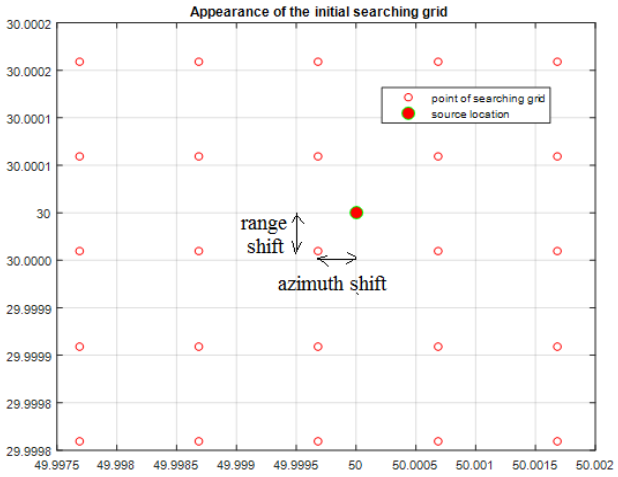

Fig. 2. Initial searching grid around the location of radio signal source (azimuth is 50º, range is 30 meters, `az_rez` is 0.001º and `range_rez` is 0.0001 m)

Fig. 2 shows an example of using the initial searching 5×5 point grid around the location of the radio signal source.

First of all, we must change dimensions of the observation window to reduce the complexity of the algorithm. The basic idea is to select a window with 5×5 points around the source location and to search for the maximum of the criterion function only in that window. Azimuth resolution is defined as `az_rez`, and range resolution is `range_rez`. In order to ensure that no location is favoured during the estimation, we will move the initial window by some random values for both, azimuth and range. These random values are in [-`range_rez`/2, `range_rez`/2] for range shift and in [-`az_rez`/2, `az_rez`/2] for azimuth shift of the window.

Our approach is to estimate the location using the arguments of the maximum of the criterion function. But it

is clear that the real maximum is not in the initial searching grid window. Because of that, we have developed the method with a moving searching grid window. If the maximum of the criterion function is on a border of the window, we must move the window toward to the left or to the right border (for azimuth) and up and down border (for range) depending on where the maximum is located. Also we must ensure the overlapping of two windows during the moving of the window. The process is over when the maximum of the criterion function is not on any border of the searching grid window. Fig. 3 shows the moving of the initial searching grid window along the azimuth and range dimension, respectively.

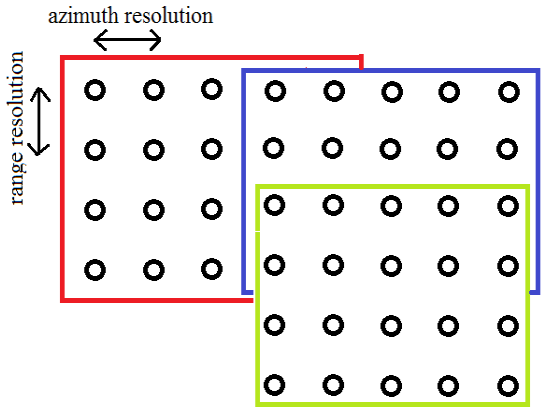

Fig. 3. The moving of the initial searching grid window (red) along the azimuth axis (blue) and along the range axis (green).

This method has a greatly reduced numerical complexity. But when we reduce the resolution cell (better resolution), it can be very hard to find the maximum of the criterion function because it will be on some border of the window for a long time (many iterations). Because of that, it again has great numerical complexity.

If the range of the source increases, it requires more time for estimation of the location, because estimation error is larger, and we must solve this problem. The solution is to use an adaptive searching grid, where resolution is better for close locations, and rougher for distant locations. This dependence is approximately linear, and will be analyzed in the next chapter of this paper.

The searching grid is adaptive and the main goal of this paper is to show and explain the performance of the proposed algorithm analyzing RMSE of the range and azimuth depending on the distance. This is the case where we change the size of the window and move the window at the same time.

IV. Simulation Results

The simulation of the hypothetical system is based on the mathematical model presented in the previous chapters of this paper and implemented with the MATLAB software package. The goal is to determine the location of the radio signal source using antenna arrays at the reception side and the adaptive MUSIC algorithm. Of course, it is first necessary to define the parameters of the hypothetical system to be simulated.

Radio signals were 16-QAM. Also, the model is also applicable to other signal classes. We used the signal model defined in (12) where q_1=0.001 and q_2=0.9. f_c is 1GHz. At the reception side, there is a circular antenna array with 5 antennas arranged in the (x,y)-plane [6]. In the first scenario, a signal source is inside the antenna array, the distance between antenna elements is 25m, and the signal source is 10m from the reference origin. Other scenarios are where it is close to the antenna array (30m) and where it is far away from the antenna array (500m). The distance between antenna elements is 1 meter for both scenarios. The vectors of the antenna positions are expressed in meters (Fig. 4.).

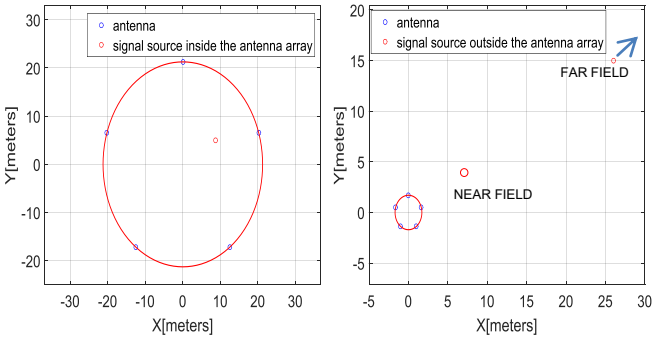

Fig. 4. Circular antenna array with 5 antennas located in the (x,y)-plane where source signal is inside the antenna array (left), and where it is outside the antenna array (right)

The model, which is presented in this paper, is generally applicable to all geometries of antenna arrays. For simplicity, it will be assumed that the antennas have identical omnidirectional characteristics. It is assumed that the additive white Gaussian noise is present. The sources are in 2D space, and they have only x and y coordinates. The signal covariance matrix is estimated based on 200 signal samples at the reception side. We also assume that the signal at the antennas have approximately equal SNR values of 20dB. Because we are analyzing RMSE of range and azimuth depending of the distance, it is important to keep this value constant. Therefore, we can follow RMSE depending only on the distance. This is ensured by increasing the power of the source signal at the distance of 1 meter from the source, bearing in mind that the power decreases with the square of the distance [7]. The azimuth angle in these simulations is 30º and does not change.

Mesh and contour plots of the modulus of the criterion function are shown in Fig. 5 for different scenarios.

The first scenario illustrates the problem of ambiguity and is interesting for application in distributed massive MIMO systems, others are interesting from the aspect of the massive MIMO system. First two scenarios show us that we can determine range and azimuth, but in the third scenario the criterion function is constant across the r-dimension, and the accuracy of the algorithm is reduced for distance estimation.

As we can see, we can estimate the location, but the searching window is too large and it has great computational complexity. The number of points where we calculate the criterion function rapidly grows when we reduce the size of the resolution cell. However, we can get localization results with similar accuracy using our approach at reduced numerical cost.

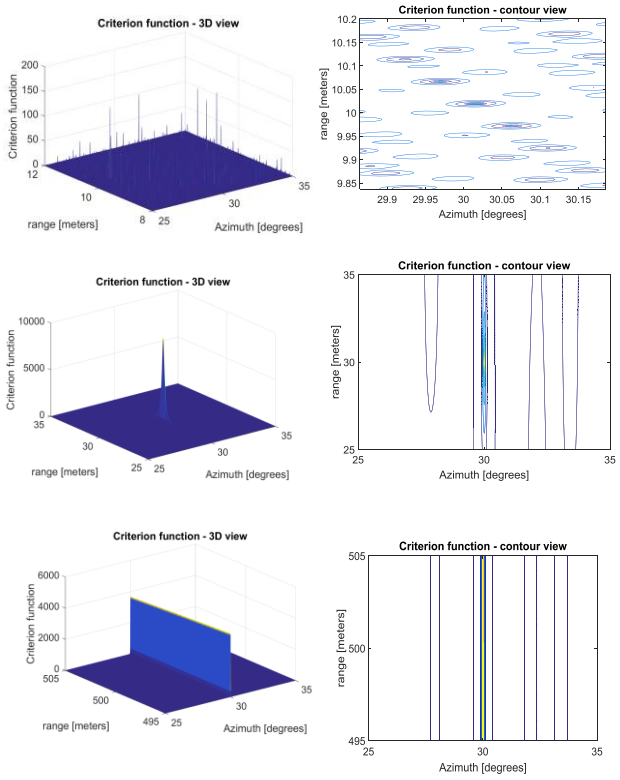

Fig. 5. Mesh and contour plots of the modulus of the criterion function for different scenarios: a) signal source is inside the antenna array and range is 10m b) signal source is close to the antenna array and range is 30m c) signal source is far away from the antenna array and range is 500m (azimuth is 30º, `az_rez` is 0.001º and `range_rez` is 0.001 m for all scenarios).

5×5 points searching grid is used, with adaptive resolution changing depending of the distance of the radio signal source from the reference origin. We propose a solution where azimuth and range resolution are different for smaller distances and for greater distances (from 50 to 500 meters): `range_rez=distance*0.00008-0.000079` meters (from 5 to 50 meters), `range_rez=distance*0.0003-0.006` meters (from 50 to 500 meters), `az_rez= 0.001/(distance+5)+0.00001` (from 5 to 50 meters) and `az_rez=0.001/distance+0.00001` (from 50 to 500 meters). 8192 simulations were made, and the first 100 estimates were shown in Fig. 6.

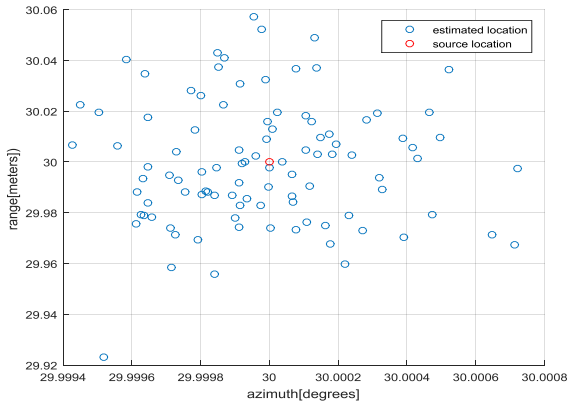

Fig. 6. Source Scatter plot of azimuth/range error (the first 100 estimates of 8192)

The proposed algorithm calculates RMSE (Root Mean Square Error) of range and azimuth depending on the distance. We use different numbers of simulations to see how the simulated results converge. Fig.7 shows the dependence of $RMSE_{distance}$ by choosing several distances where sources were located. We choose different values of SNR at antenna array. In this case, the distance axis is in logarithmic scale.

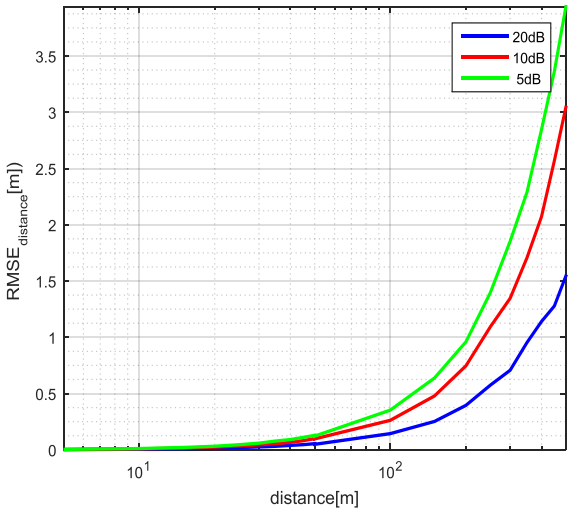

Fig. 7. $RMSE_{distance}$ for different distances of radio signal source and for different values of SNR at antenna array (from 5 to 500 meters) where signal source is outside the antenna array

As we can see from the plot, RMSE increased with the distance, especially for greater distances. This is definitely an expected result. But for smaller distances it is very hard to show the $RMSE_{distance}$ because the error is too small. Because of that, we have to show a plot for smaller distances from 0 to 50m (Fig. 8) and for different values of SNR at antenna array. These values directly affect the performance of the proposed algorithm.

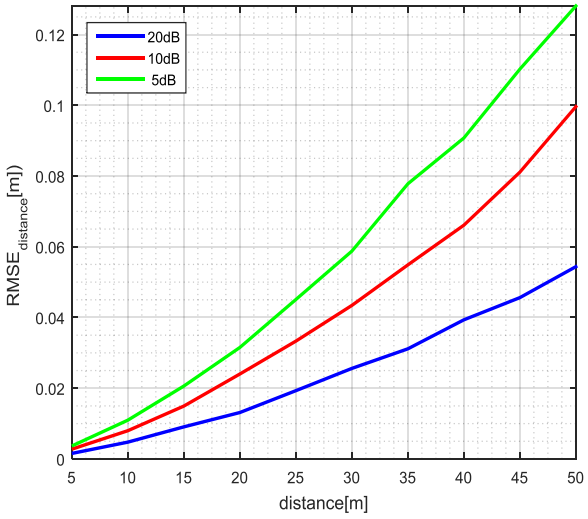

Fig. 8. Plot of $RMSE_{distance}$ for different distances of radio signal sources (5 to 50 meters) and for different values of SNR at the antenna array where signal source is outside the antenna array

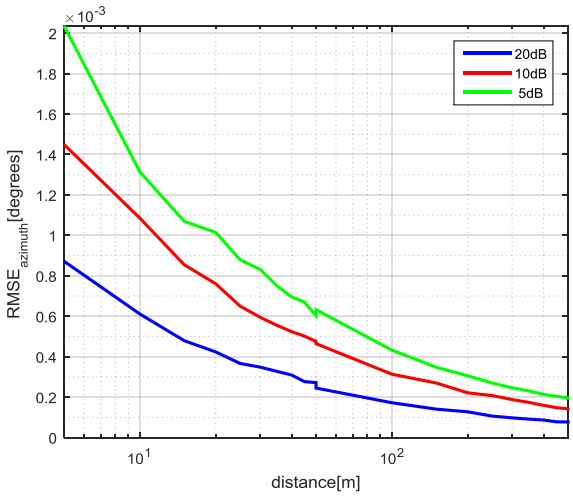

Fig. 9. $RMSE_{azimuth}$ for different distances of radio signal sources (from 5 to 500 meters) and for different values of SNR at antenna array where signal source is outside the antenna array

$RMSE_{azimuth}$ was shown in Fig. 9 and it decreases as the distance increases. The estimation error is smaller for larger values of SNR at the antenna array. If the number of simulations is greater, the RMSE estimates are more accurate and converge to the real value.

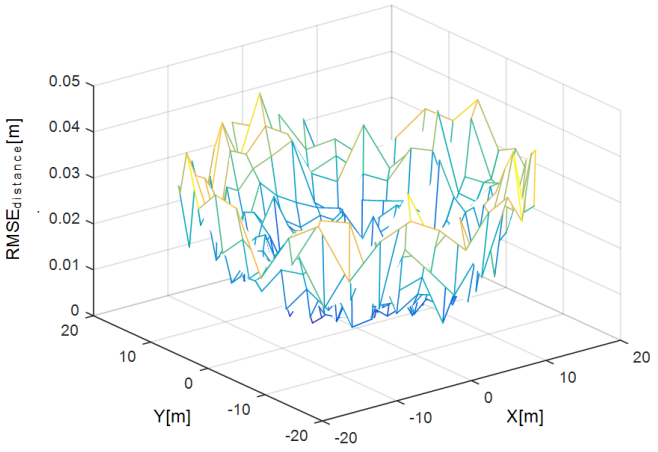

Fig. 10. $RMSE_{distance}$ for different distances of radio signal sources (from 1 to 20 meters) and for all azimuths where signal source is inside the antenna array

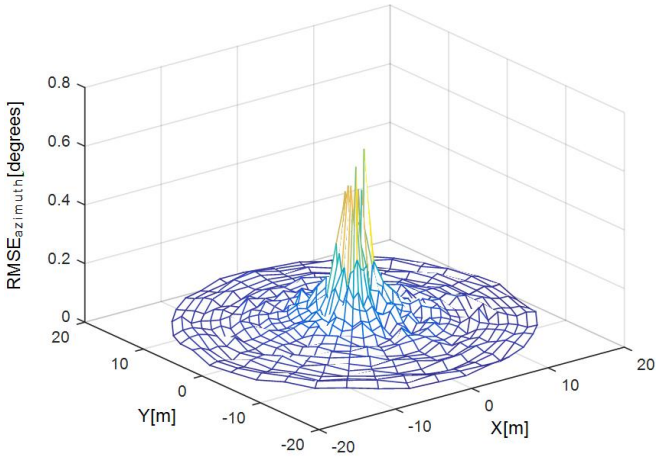

Fig. 11. $RMSE_{azimuth}$ for different distances of radio signal sources (from 1 to 20 meters) and for all azimuths where signal source is inside the antenna array

Fig. 10 and Fig. 11 show the $RMSE_{azimuth}$ and $RMSE_{distance}$ for all azimuths and for different distances of radio signal sources where radio signal source is inside the antenna array. As we can see, symmetry can be noticed and azimuth estimation is less accurate then it was in previous cases where signal source was outside the antenna array.

V. Conclusion

In this paper, we presented a localization algorithm where we simultaneously estimated the range and azimuth of the radio signal sources. A modified-version of the 2D MUSIC algorithm gives good results but the drawback is a heavy computational load. To solve this problem, we used an adaptive searching grid, where resolution is better for close locations, and rougher for distant locations. We have changed the size of the searching grid window and moved the window at the same time. It was shown that different SNR values at the antenna array directly affect the performance of the proposed algorithm. We also showed the RMSE of the range and azimuth for different scenarios, where signal source is inside the antenna array, where it is close to the antenna array and where it is far away from the antenna array. We showed and explained the results.

Implementation of algorithm for excision of point targets from distributed radar detections

Pavle Petrović, Nemanja Grbić, Nikola Stojković, *Member, IEEE*, Dejan Nikolić, *Member, IEEE*, Nikola Lekić, *Member, IEEE*

***Abstract*—With maximal range of 200 nmi HFSWR (High Frequency Surface Wave Radar) represents a very effective solution for remote sensing of wide maritime areas. Although HFSWR may be used for many purposes, in this paper the focus is on vessel detection. Since any vessel fits into one HFSWR resolution cell all of them are considered point-like targets. In some circumstances it was noticed that reflections from vessels are occupying multiple consecutive cells, thus forming falsely distributed targets. The paper proposes an algorithm which solves this anomaly by pinpointing vessels exact location within distributed area. The algorithm is tested on real data collected from HFSWR systems located in Gulf of Guinea.**

***Index Terms*—radar, HFSW radar, CFAR detector, Ship detection, marine systems.**

I. Introduction

IN recent years a demand for monitoring of the deep seas is rising. One of the solutions lies in the usage of HFSWR (High Frequency Surface Wave Radar). A general overview of HFSWR principles can be found in [1-3].

HFSWR being discussed in this paper is described in detail in [4] and only a brief overview of it will be presented here. Radar site geometry is presented in Fig 1.

HFSWR transmitter and receiver are separated, each with its own antenna array. Transmitters role is to generate a signal of desired strength and direct it towards a region the HFSWR is designed to monitor.

To accomplish this it is equipped with power amplifiers and planar antenna array consisting of 4 quarter wave monopole antennae [5]. Radiation pattern of such array is presented in Fig. 1. HFSWR receiver array contains 16 quarter-wave monopole linear array, each connected to a dedicated RF receiver. Signal received by each antenna is RF processed and digitalized separately. Further processing of digitalized signal is done on data from all 16 channels conjointly.

The rest of the paper is organized as follows: in section II a short description of signal processing techniques and challenges in which advances are made is presented. Section III presents the details of Excision Algorithm. Section IV consists of data collected from an HFWSR site and presents the advances achieved by the implementation of said algorithm. Conclusions and possible future research topics are given in section V.

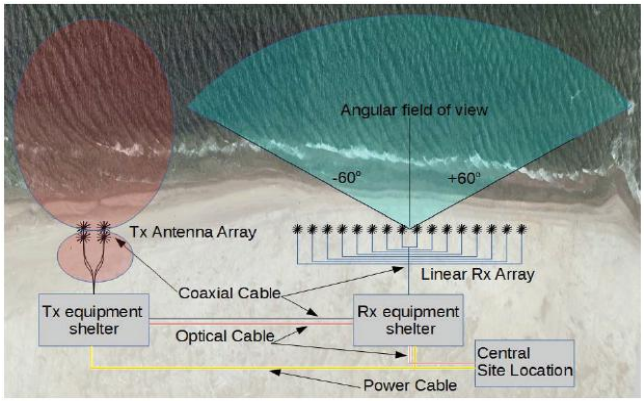

Fig. 1. HFSWR deployment zone.

II. Signal processing in HFSWR and challenges addressed in this paper

Block schematic of the digital signal processing (DSP) chain is presented in Fig 2. and its detailed description is given in [1], [6]. The focus of this paper is on the way how to improve design of CFAR (Constant False Alarm Rate) detection algorithms in a non-homogeneous clutter environment. Since CFAR algorithms perform the best when the environment contains only homogeneous noise any source of non-homogeneous clutter will degrade their performance. In HF band Bragg lines are a dominant source of non-homogeneous clutter. They form when wavelength of a reflected electromagnetic wave is equal to double the distance between peaks of sea waves [7]. Additionally, HF electromagnetic waves can interact strongly with ionosphere, causing hardly predictable behaviours resulting with localized, but non-homogeneous clutter. Both of these effects lead to increase of false detection, which requires specific algorithms in order to maintain reasonable false alarm rate. Some previous work regarding these problems may be found in [8], [9].

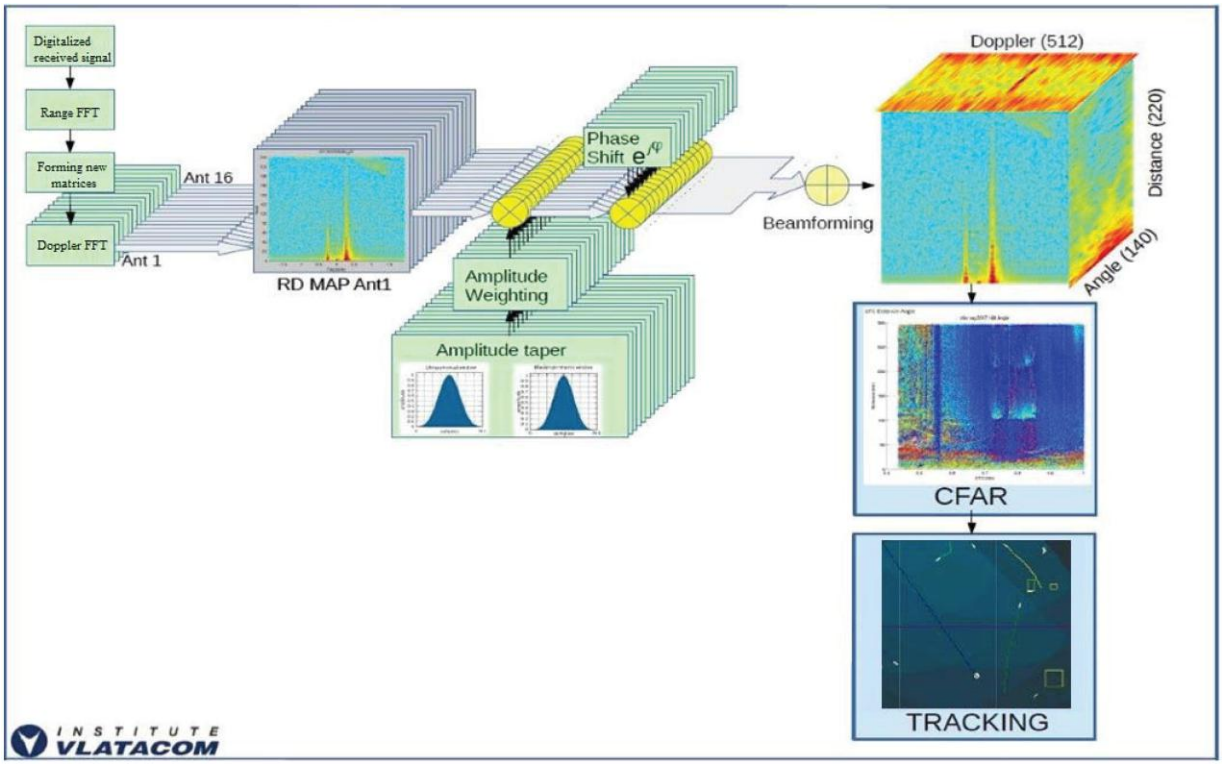

Fig. 2. HFSWR signal processing chain (taken from [4])

During regular operation of HFSWR a number of distributed targets were observed, which may be consequence of non-homogeneous clutter environment. A distributed target is characterized by a number of detections from CFAR that have one or two equal coordinates (coordinates being range from radar, azimuth angle relative to true north and radial speed relative to receiver array) while the rest of coordinates differ by a small amount, as little as one resolution cell. In other words, those targets occupy multiple adjacent resolution cells. When the positions of these distributed targets are compared with data received from AIS (Automatic identification system) [10] it becomes clear that this distribution originates from single vessel, not a group of vessels. An example is presented in Fig. 3.

Fig. 3. Falsely Distributed detection. Four red markers represent detections found by CFAR while a white marker under them represents position received from AIS.,

To the best of our knowledge little attention is paid to this occurrence and no adequate solution could be found. These detections will move with the ship so tracker will rarely be able to eliminate them, since they will form tracks parallel to the track of the true ship detection [11]. In this way a group of vessels are created in Command & Control system in place of a single vessel. For that reason an algorithm that can properly eliminate false targets, while simultaneously maintaining true targets is needed. Additionally, it should, as much as possible, be able to recognize and avoid discarding detections that originate from multiple vessels sailing closely to each other.

III. Description of the Proposed Excision Algorithm

Excision algorithm implemented here operates on 3-D data structures called RDA Cubes (Range Doppler Azimuth Cubes). They consist of 200 × 140 × 512 fields, each of which can be declared a detection by CFAR algorithm. Each of these fields is a result of previous signal processing, and contains information about signal level received from a particular resolution cell. Dimensions of the RDA cube are related to the resolution HFSWR. In this implementation they contain information about 200 range resolution cells, 140 azimuth resolution cells and 512 Doppler shift resolution cells. These parameters dictate the dimensions of cube axes [4]. Excision consists of four steps:

1. Chose one of CFAR detections.
2. Form a sub-window around picked detection such that none of its outer cells are designed as detections by CFAR.
3. Using cells contained inside a sub-window calculate the most probable position of the target.

4. Keep the most probable detection while discarding the rest.

These steps are repeated until there are no more detections to be processed. In this implementation detections are listed by azimuth angle and they are processed in that order. The list of detections needs to be refreshed after each iteration because excision can (and often will) discard some detections. Detections that are once declared excised are not processed again.

It is important to ensure that sub-window is large enough to encompass whole falsely distributed target, but small enough so it doesn't encompass multiple closely spaced point-like targets, whenever it is possible. It was concluded empirically that most of falsely distributed targets are multiplied along only one detection parameter (range, Doppler shift or azimuth). Because of that, and the fact that 3-D data structures that are structured like a cuboid (for example three dimensional matrices in Matlab) are convenient to work with, sub-window extending is done in six directions: in a positive and a negative way along each axis. If there exists a detection in one of six faces of a sub-window in the current iteration, sub-window is extended in those directions. A simplified, two dimensional sub-window forming is presented in Fig. 4.

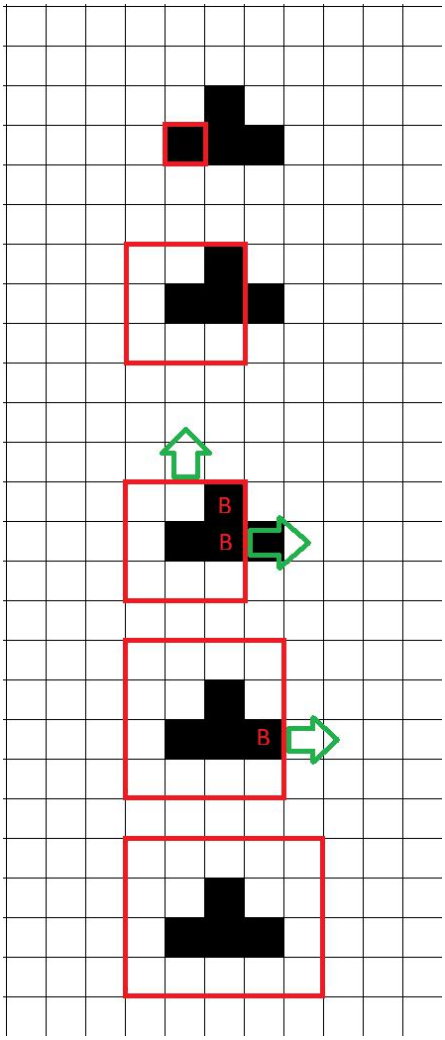

Fig. 4. Steps of sub-window forming for four connected detections in two dimensions, shown as black fields. Sub-window is presented as a red rectangle, directions of expansions as green arrows and detections found in outermost layer of a sub-window are marked with a red letter "B".

A single detection is chosen (marked with a red square, first from top in Fig. 4.) and first iteration of sub-window is formed from all the cells bordering it. Then all the cells contained in bordering layer of a sub-window are checked for detections. In the example from Fig. 4. two detections are found, existing in top and right face of a sub-window. Sub-window is expanded in those directions. These steps are repeated until there are no more detections in the outermost layer of a sub-windows (Fig. 4. bottom).

In the next step, a detection with the highest SNR (Signal to noise ratio) is picked. This will be used as a reference point. From that point all the other detections included in a sub-window are listed. Starting from them, position shift vector is calculated relative to reference cell using the weighting function. Cumulative position adjustment vector $\mathbf{P_{shift}}$ is calculated as shown in (1), while weighting function w in this implementation is shown in (2).

$$\vec{P}_{shift} = \sum_{i=0}^{n_{det}} \frac{\vec{P}_i - \vec{P}_{ref}}{\left\| \vec{P}_i - \vec{P}_{ref} \right\|} w_i; \tag{1}$$

$$w_i = \frac{10^{\frac{-(SNR_i^{dB} - SNR_{ref}^{dB})}{20}}}{2}; \tag{2}$$

Where n_{det} is the number of detections found inside the sub-window, $\mathbf{P_{ref}}$ represents the coordinates of a detection with the highest SNR, while $\mathbf{P_i}$ are coordinates of i-th detection listed in a sub-window. The unit of measurement of $\mathbf{P_{shift}}$ is resolution cell: a position adjustment vector of amplitude 1 will move the calculated position of the target in the given direction by one resolution cell. Separate coordinates of the target are calculated from amplitude and angle of $\mathbf{P_{shift}}$ and are converted to real units (km for range, degree for azimuth and Hz for Doppler shift).

The result of such a weighted method is that detections that are closer to the reference and have a SNR closer to it are going to have a greater influence on its position. This characteristic allows interpolation of a targets position based on several discreet measurements. A simple example would be two detections of very similar SNRs, detected at the same range and with a very similar radial speed, only differing by one azimuth resolution cell. To decide that the ship is exactly in one or the other resolution cell would not be accurate enough. Considering that the signal level in both cells is similar it is safe to assume that the target is somewhere between them. In this particular case excision algorithm is going to result in a position shift along the line connecting two detections, while the amplitude of this shift will be inversely proportional with the difference in SNR difference: theoretically, if the two detections have exactly equal SNRs final position of detection will be calculated as the middle of the line segment between the two detections.

Considering that this algorithm needs to perform in real time remote sensing system it is important to evaluate its complexity. For that purpose the worst case scenario will be discussed. A distributed target composed of n individual targets is used for that analysis. From the point of steps required for sub-window forming the worst case scenario is having all the distributed detections aligned in a single line. In that case full sub-window forming will take n-1 steps.

Every other configuration of bordering targets will be completely enclosed at least as fast as that because at least one step will have a chance of enclosing more than one detection at the same time. Complexity of this step is evaluated as O(n). Finding a detection with maximal SNR is a well known problem which has a complexity of O(n). Lastly, position shift vector for each detection except the reference one is calculated as shown in Eq. 1. Calculation time grows linearly with the number of detections inside sub-window, giving this step the complexity of O(n). These three steps combined give the entire algorithm a linear complexity, or O(n).

IV. Field tests

This algorithm was implemented in C++ programming language where it is applied on a preliminary detection list generated by CFAR. Test samples are samples of real data collected from two HFSWRs operating in Gulf of Guinea, Africa. A distributed target shown in Fig. 3. is the result of CFAR algorithm without excision algorithm applied. The same CFAR detection file is processed by excision algorithm and the same region shown in Fig. 3. is shown in Fig. 5.

Fig. 5. Detection excised from a distributed target (red marker). Informations about ship from AIS (white marker) are showed on the right.

From Fig. 5. it can be seen that the position of radar target is now unambiguous. Exact positions of falsely distributed targets (FDT rows) and resulting target after excision, along with distances from AIS position are given in Table I.

Table I
Positions of targets before and after excision

Marker	Latitude	Longitude	Distance from AIS
AIS	N 6.10009°	E 3.57250°	/
FDT1	N 6.09575°	E 3.58583°	1.55 km
FDT2	N 6.10222°	E 3.58000°	0.86 km
FDT3	N 6.11424°	E 3.56889°	1.64 km
FDT4	N 6.10816°	E 3.57389°	0.91 km
Excised	N 6.10863°	E 3.57232°	0.94 km

It is important to note that AIS is only used for confirming already detected targets, not for detection, but here it will be used as a reference for accurate position of the target. Even though excised detection is not the most accurate one, in comparison with position reported by AIS, mean value of distances from AIS of all falsely distributed targets is almost 35% higher than the distance of excised target form AIS. Additionally, total number of detections is decreased when excision is applied, thus false alarms are significantly reduced. Considering the whole system has to process all the data from one integration cycle before the next set of data arrives this reduction in number of targets that need processing is of great importance.

The time needed for the excision algorithm alone was not measured separately for it is eclipsed by the time needed to perform the CFAR algorithm. The time needed for the entire step of detection does not seem to vary more than several tens of milliseconds depending on whether excision is turned on or off. Considering that the duration of entire CFAR step of HFSWR is on the order of several seconds, a delay like that is negligible. Fig. 6. shows times needed to perform entire CFAR algorithm with and without excision algorithm applied.

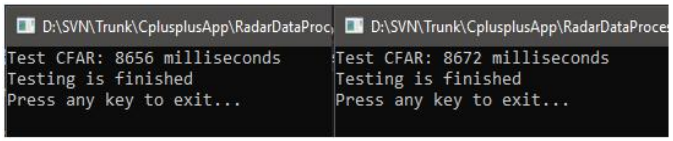

Fig. 6. Execution times for entire CFAR step without excision (left) and with excision enabled (right).

It is clearly shown that execution time difference is negligible, since it adds only around 16ms to the total CFAR execution time.

Significant reduction to the number of detections of CFAR output files allows for parameters of CFAR to be set so that the threshold will be lower, thus letting more detections, false and true, to be found. Most of the false detections resulting from waves, which are distributed by nature, will then largely be annulled by excision algorithm, leading to a smaller number of detections overall, while a lower threshold will allow for vessels that are further away to be detected. Tracker will then be responsible for discerning detections stemming from vessels from leftover detections stemming from waves. Fig. 7. shows one such situation, where light blue cone describes the zone in which HFSWR is projected to detect and track ships. Fig. 7. shows that in the main coverage area of the radar excision algorithm successfully filtered out most of the detections that were falsely distributed. It can be seen that calculated detection positions are closely related to positions received from AIS. Additionally, it can be seen that ships that are more than 200km away from HFSWR are successfully detected. Positions of those distant targets can be estimated with more precision by applying multi radar multi target fusion algorithms to data originating from multiple HFSWR systems covering the same area [12]. Targets detected outside its cone (left and right) are generally less accurate because of beam widening when receiver beam is steered so far off of bore-sight (more than 50° in either side).

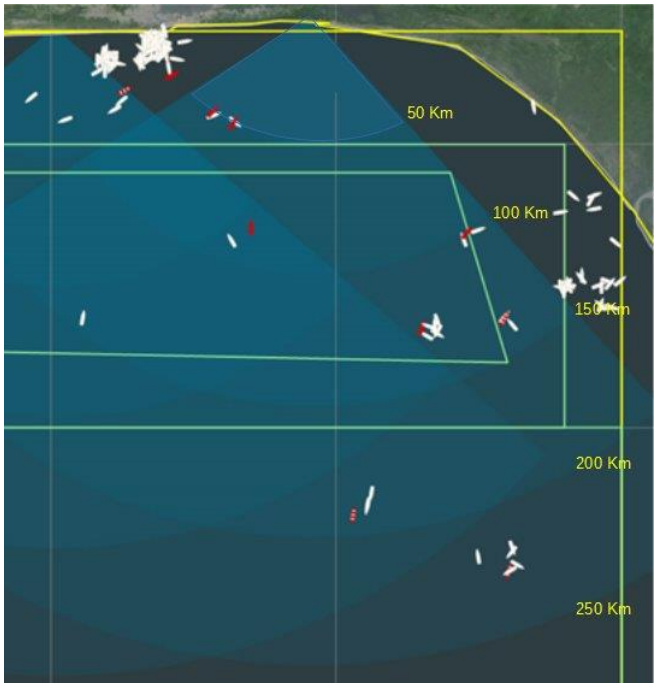

Fig. 7. Detections (red markers) correlated with AIS (white markers) after performing excision algorithm. Each arc represents 50km range away from radar.

Please note, two targets residing in the same range-angle cell, but having different Doppler shift can easily be differentiated by their radial speed. However, two targets that are in the same range and azimuth resolution cell can be merged into one in they have a very similar radial speed, if any of them is distributed. In practice such situation may be resolved by further signal processing, i.e. multi-radar fusion algorithm [12], [13]. However, a potentially better solution could be found during future research.

V. Conclusion

In this paper an example of how post-processing of CFAR detection data can be used to eliminate uncertainties related to target position. Algorithm for excising distributed targets is implemented and tested on real data collected from operating HFSWR systems located in the Gulf of Guinea. It was shown that, when applied, excision algorithm reduces the number of false targets while performing a type of interpolation to deduce where a real radar target is most probably located.

For the future work authors intend to continue optimisation of the weighting function in order to improve algorithm effectiveness.

Analysis of different window function effects on DBF in HFSWR signal processing

Nemanja Grbić, Pavle Petrović, Dejan Nikolić, *Member, IEEE*, Nikola Stojković, *Member, IEEE,* Vladimir Orlić, *Member, IEEE*

***Abstract*—In this paper a few implementations of Digital Beam-forming (DBF) technique used in High Frequency Surface Wave Radar (HFSWR) signal processing are examined. All of them are based on phase shifting principle, but differ in so called "window" functions used for preparation of the data during the beam-forming process. Three different sets of magnitudes of weights used to form Hamming, Blackman and modified Blackman, window functions will be evaluated in this paper. Although choosing an optimal window function is situational, in this paper it is shown that for HFSWR DBF algorithm, modified Blackman can be regarded as the window of choice. Data used for this evaluation is obtained from HFSWR sites located in the Gulf of Guinea.**

***Index Terms*—HFSWR, DBF, Window functions, main lobe, side lobes.**

I. Introduction

MARITIME criminal activities and political disputes of areas away from territorial waters are an increasing occurrence, dealing significant damage to economies and endangering lives in the process. In order to take any action at all, consistent surveillance of the maritime area is mandatory. Not only does this apply to territorial waters, but for the entirety of the Exclusive economic zone (EEZ) [1] as well. Since EEZ consists of a 200 nautical mile (370 km) strip of water from the shoreline, some nations have hundreds of thousands of square miles of area to cover. Adding further to difficulties is the curvature of the earth preventing direct line of sight. Even though this all seems quite difficult, there are ways to monitor the EEZ.

One approach utilizes optical and microwaves sensors. To bypass their limitation, which is their range and direct line of sight requirement, these sensors are mounted on mobile platforms, such as satellites, air planes, ships, etc. However, this introduces limitations of the mobile platforms. The need to resupply these platforms, them being manned or unmanned, presents a drawback to EEZ monitoring which needs to be done constantly. Poor weather conditions can completely prevent deployment of mobile platforms.

Another approach is to use a network of long range stationary sensors, specifically high frequency surface wave radars. These provide detection well beyond the horizon due to surface waves following the curvature of the earth, therefore, eliminating direct line of sight requirements [3]. Since these radars are stationary, data availability is much more consistent compared to mobile platforms approach. Another important advantage these radars have is their much lower annual upkeep cost.

However, HFSWR has its disadvantages. Most notable one being its size, specifically, the area of land needed to deploy an HFSWR site [3]. In some areas of the world, finding a suitable location to fit both tactical and technical needs can be quite difficult. In some cases, these are remote locations far from settled areas. This creates logistical challenges such us communication, power routing and travelling conditions for maintenance crews. In order to ensure both unmanned and constant operation, various control algorithms are mandatory [4], [5]. Finally, there are different environmental [6] and man-made [7] factors that need to be accounted for, further increasing the system's complexity.

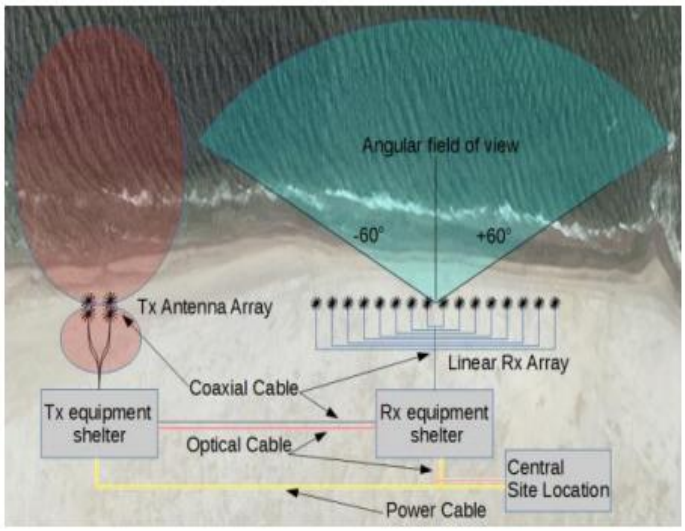

Fig. 1. Usual OTHR site deployment [3].

Vladimir Orlić is with VLATACOM Institute, Bulevar Milutina Milankovica 5, 11070 Belgrade, Serbia(e-mail: vladimir.orlic@vlatacom.com).

HFSWR consists of 2 antenna arrays, transmitter and receiver array. Additionally, some HFSWR sites are equipped with additional support equipment, power suppliers, communication equipment, and armed security. The Rx array consists of 16 quarter wave monopole antennae [8] with spacing between each element being 0.5 wavelengths. To ensure multiple HFSWR sites do not interfere with each other different operating frequencies are used.

II. DBF AND EXAMINED WINDOW FUNCTIONS

Complete signal processing is described in detail in [9]. In this paper main focus is on DBF. Input for DBF are so called Range Doppler (RD) maps. RD maps are matrices created using range and Doppler processing [9], done for each angle of incidence within the angular field of view. This is done for each antenna individually.

Each element of a single RD map for one antenna is multiplied by a complex weight coefficient, phase-shifting beam-forming [10]. A set of complex weight coefficients is formed by multiplying the steering vector for the angle of incidence of the current RD map by a set of real numbers.

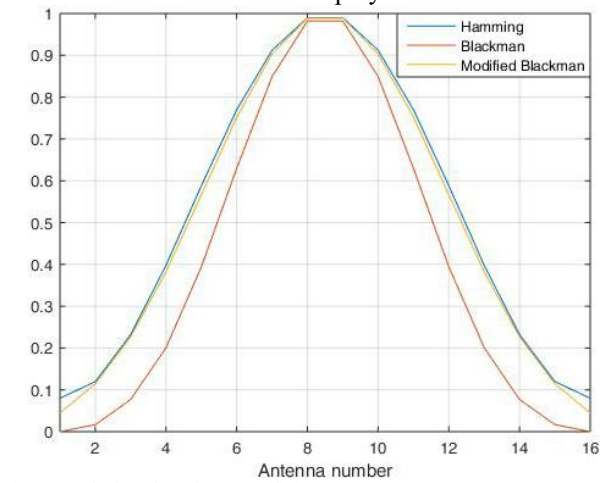

Fig. 3. Window functions coefficients.

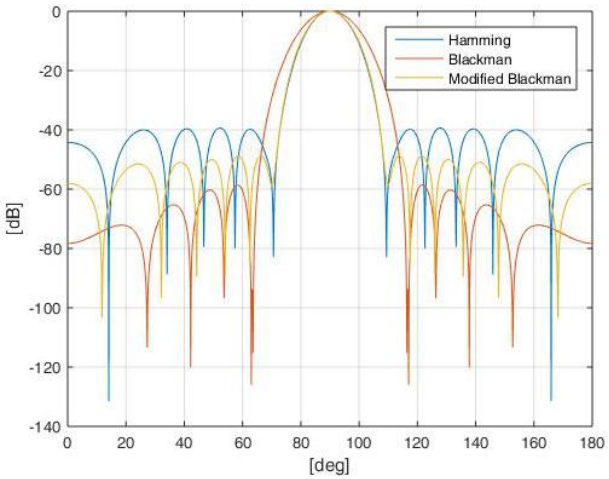

Fig. 4. AF generated using mentioned window functions.

This set of real numbers is the window function mentioned, and it affects array factor (AF), most notably main lobe width and side lobes intensity. Three window functions will be analyzed, Hamming [11], Blackman [11], and modified Blackman which will be explained in this paragraph. Figure 3. shows coefficients for all three window functions. Figure 4. shows array factors for those three windows. Both figures are generated using matlab. Equation (1) is the analytical form for Hamming window function, where $0 \le n \le M$ with M+1 being the window length,

$$w(n) = 0.54 - 0.46\cos(\frac{2\pi n}{M}) . \quad (1)$$

Equation (2) is the analytical form of Blackman window function, where $0 \le n \le M-1$, with N being the window length, while M is N/2 when N is even and (N+1)/2 when N is odd,

$$w(n) = 0.42 - 0.5\cos(\frac{2\pi n}{L-1}) + 0.08\cos(\frac{4\pi n}{L-1}) . \quad (2)$$

The other half of the window is obtained by flipping the first half around mid-point.

By comparing AF for Hamming and Blackman window functions it can be seen that Blackman window function gives a wider main lobe while drastically reducing side lobe levels. However, it can be seen from fig 3. that the weight coefficient amplitudes on the ends are practically zero. This means that antennae 1 and 16 have little influence on AF making them redundant. To avoid this, Blackman window was modified and tested. Modification is done by generating a set of Blackman coefficients for 20 members, but leaving the first two, and last two out of the window function. This solution is a compromise between Hamming window and default Blackman window function. The reason why rectangular window, which has the narrowest main lobe, is not mentioned is because of its pronounced side lobes. It was estimated that lower side lobe intensity is needed for HFSWR. Characteristics of all three AF are displayed in the following table.

TABLE I
ARRAY FACTOR CHARACTERISTICS

Window type	Main lobe 3 dB width [deg]	The first side lobe compression [dB]
Hamming	10.8939	39.2
Blackman	13.8923	58.62
Mod. Blackman	11.0983	48.83

III. TEST RESULTS

Range Doppler Angle (RDA) cubes, contain information about target radial speed and position (angle and distance). Using RDA cubes sampled from HFSWR in the gulf of Guinea, three beam-formers were tested

From an RDA cube itself, it is difficult to see the influence of beam-forming. However, taking an RA (Range Angle) map, from the RDA cube, for one specific Doppler frequency, allows for clear perception of beam-former influence. To confirm that results from RA maps are in fact targets, synchronization with Automatic identification system (AIS) was used. AIS and its synchronization with HFSWR are covered in detail in [12-14].

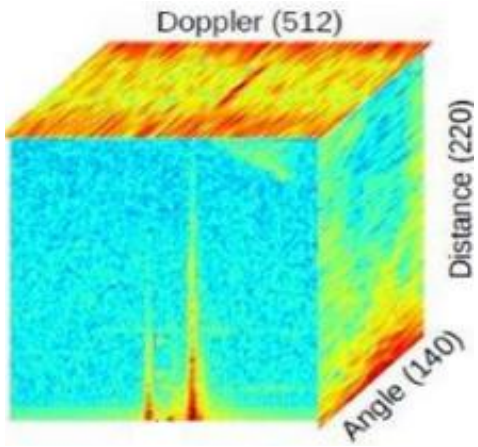

Fig. 5. RDA cube structure.

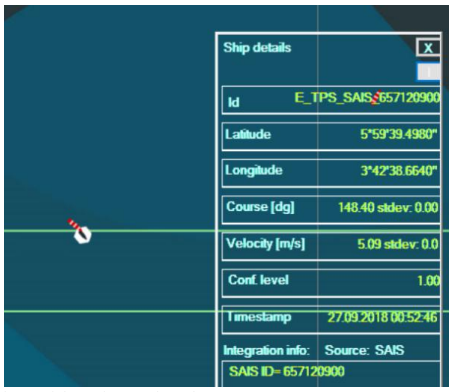

Fig. 6. Tracker with estimated and AIS targets.

The white ship symbol in the picture represents an AIS target. The red ship symbol represents HFSWR estimates after beam-forming and Constant False Alarm Rate (CFAR). From AIS, the target's exact position and velocity can be seen. This means that all RDA parameters for the target are known, and allows for an appropriate RA map to be chosen. The target is about 60 km from the site near the edge of HFSWR field of view.

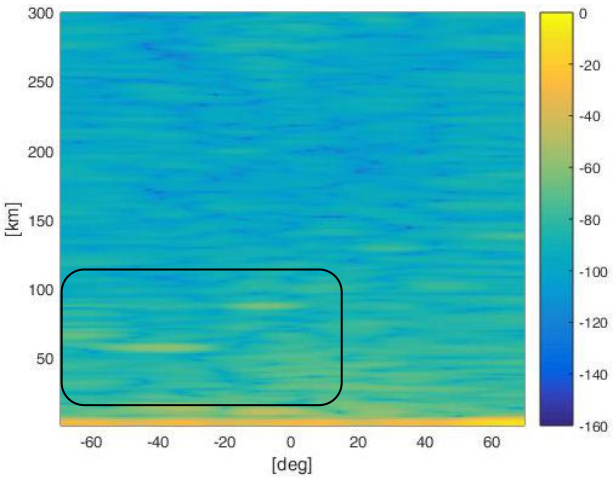

Fig. 7. Chosen RA map with highlighted target area.

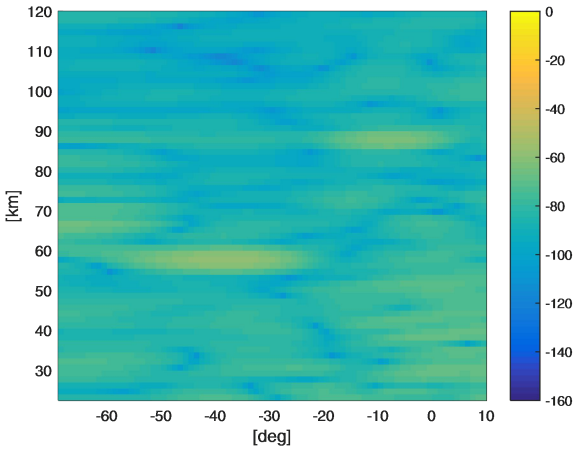

Fig. 8. Highlighted area displaying the target at 57 km range.

The RA maps on Fig 7. and 8. are made using Hamming window and their purpose is to demonstrate real data based on relevant parameters. Since "naked eye" cannot easily notice what difference different window functions have on target distribution in RA map, the maps are reduced to logarithmic amplitude versus angle plot at specific range. Since target is located at 57 km range, normalized logarithmic amplitude versus angle plot is given for that distance (Fig. 9).

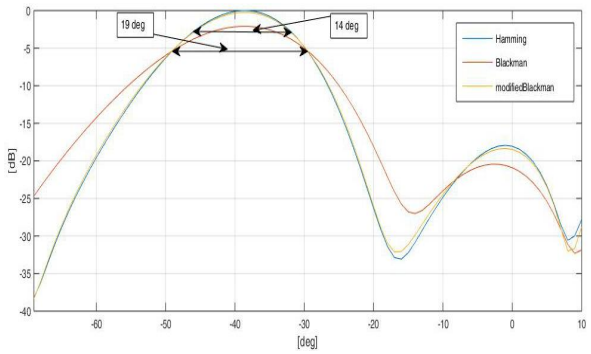

Fig. 9. Normalized logarithmic amplitude versus angle at 57 km range, with marked 3-dB main lobe width.

From Fig. 9. it can be seen that the target is distributed over arc nearly 20 degree wide. The reason for this is AF main lobe width. From table I it can be seen that all analysed window functions give at least 10 degrees of 3 dB main lobe width, which in turn gives a wide-angle displayed target. As mentioned, there are more steps in the signal processing after beam-forming that address this issue. However, a narrower main lobe is always desirable. From the presented plot it can be seen that Blackman window function displays the target over a wider area compared to the other two due to its AF having a wider main lobe. Although theoretical side lobe levels are at least 40 dB less than signal level (see Fig. 4.), in figure 9. it can be seen that are approx. 25 dB less than signal level. In RA the side lobes are manifested as constant range lines, which are interrupted due to AF shaping function influences. Their signal level is considerably lower than that of the real target and in most cases they will be eliminated during consecutive signal processing steps. However, sometimes this effect can cause appearance of false alarms.

IV. Conclusion

The advantage of DBF is that it is entirely done with software, so any changes to the beam-former can be immediately implemented. Henceforth, 3 window functions are described and evaluated here. It is worth noting that choosing an appropriate window function can be difficult and entirely situational, since it comes down to a compromise between main lobe width and side lobe intensity. In the case presented in this paper the modified Blackman window function shows the best performance since it provided the best of trade of between main-lobe width and side-lobes compression.

For the future work, more complex window functions will be implemented and tested at the various data sets in order to find the optimal function for the targeted application.

Implementacija tunelovanja Q-SIG preko SIP u privatnoj telefonskoj mreži sa integrisanim uslugama funkcionalnog korisnika

Slađan Svrzić, Zoran Čiča, Zoran Miličević i Zoran Perišić

***Apstrakt*— U radu se daje objašnjenje za novi način povezivanja ISDN PABX i IP orijentisanih PABX (PINX) u privatnoj automatskoj telefonskoj mreži integrisanih usluga funkcionalnog korisnika, primenom postupka tunelovanja mrežne Q signalizacije (Q-SIG) kroz privatnu IP mrežu (Intranet) sa SIP. Dat je kratak prikaz Standarda ECMA-355 za postupak tunelovanja Q-SIG kroz IP/SIP mreže i opisana je njegova praktična primena na delu automatske telefonske mreže integrisanih usluga, za međusobno povezivanje učesnika sa različitih krajnjih ISDN/Q-SIG PABX, preko tranzitnih IP/Q-SIG PINX, a pri čemu IP/SIP mreža ima ulogu Interventne mreže (*Intervening Network*, IVN).**

***Ključne reči*— Privatna automatska telefonska mreža integrisanih usluga; Q signalizacija; tunelovanje Q-SIG; IP orijentisane PABX.**

I. UVOD

Q-SIG je signalizacioni sistem koji je dizajniran za upotrebu u korporativnim telefonskim mrežama (*Corporate Telephony Network*, CTN). Standardizovan je na globalnom nivou i podržan od strane vodećih svetskih proizvođača Privatnih automatskih telefonskih centrala (*Private Automatic Branch Exchange*, PABX) [1]. Koristeći proverenu ISDN i IP tehnologiju, Q-SIG obezbeđuje opseg osnovnih i dopunskih usluga za poboljšanje poslovnih rezultata korisnika privatnih telekomunikaciono-informacionih sistema. Q-SIG je jedini sistem signalizacije za korporativne mreže koji obezbeđuje nezavisnost od proizvođača i garantovanu interoperabilnost na globalnom nivou [1].

Q-SIG protokol mrežne signalizacije funkcioniše između PINX (*Private Integrated services Network eXchange*) u okviru privatne mreže sa integrisanim uslugama - PISN (*Private Integrated Services Network*) [2]. U okviru PISN se putem režima komutacije kola korisnicima obezbeđuju kako osnovne, tako i dopunske usluge [3]. U okviru Standarda ECMA-143 (*Upravljanje pozivima u podršci osnovnim uslugama*) [4], zatim u Standardu ECMA-165 (*Generički funkcionalni protokol za podršku dopunskim uslugama*) [5], kao i u nizu drugih standarda koji određuju pojedinačne dopunske usluge, specificirana je uloga Q/SIG za podršku tim uslugama. Ime Q-SIG je izvedeno iz činjenice da se koristi za signalizaciju u "Q" referentnoj tački PINX. "Q" referentna tačka je logička tačka razgraničenja, tj. nalazi se na krajevima logičke veze dve PINX, koja se naziva inter-PINX linkom (IPL). Fizička veza sa svakom od PINX vrši se na referentnoj tački „C". U tom slučaju, ulogu IVN (*Intervening Network*) mogu preuzeti namenski kanali za komunikaciju (analogni ili digitalni) ili komutirane komunikacije (za virtuelne privatne mreže) [1].

U ostatku rada je u okviru drugog poglavlja predstavljena Q-SIG u okviru SIP IP. U trećem poglavlju opisana je primena tunelovanja Q-SIG preko SIP IP u okviru PISN funkcionalnog korisnika, kroz predloženi i testirani model mreže. Na kraju su data zaključna razmatranja.

II. Q-SIG U OKVIRU SIP IP

ECMA-355 je standard koji veoma uspešno produžava upotrebu Q-SIG i u IP orijentisanim privatnim telefonskim mrežama (*Private Telephony Network*, PTN) [6], tako što specificira tunelovanje Q-SIG preko *Session Initiation Protocol* (SIP) [7]. Tunelovanje Q-SIG preko SIP omogućava međusobno pozivanje između PABX, "ostrva" mreža sa komutacijom kola koje koriste Q-SIG, i u slučaju da su one međusobno povezane IP mrežom (koja koristi SIP) [8], i to bez gubitka Q-SIG funkcionalnosti. Ovaj standard olakšava uvođenje novih poboljšanih SIP i *Session Description Protocol* (SDP) funkcionalnosti [9], a koje su specificirane nakon objavljivanja ranijih izdanja ovog standarda. Ta poboljšanja uključuju mogućnost primene zaštite korisnog signala i mehanizme za funkcionalniju razmenu informacija preko SDP, kao i primenu novouvedenog indikatora za uočavanje promena u proceduri signalizacije.

Standard prvenstveno specificira tunelovanje Q-SIG preko SIP protokola u okviru korporativnih telefonskih mreža, a koji se obično odvija preko IP mreže, pri čemu se telefonski pozivi smatraju vrstom multimedijalne sesije u okviru koje se razmenjuju samo audio signali [8].

Često su velike CTN takve arhitekture da sadrže granične PISN koje koriste Q-SIG, kao i sopstvene centralne IP mreže koje koriste SIP. Tada postoje dva slučaja u scenariju pozivanja između učesnika. U prvom slučaju, Q-SIG poziv ili Signalna konekcija nezavisna od poziva (*Call Independent Signalling Connection*, CISC) mogu poticati od "A" učesnika

Sl. 1. Raspored entiteta kod realizacije poziva od Q-SIG, preko SIP, na Q-SIG [6].

spojenog na PISN i završiti kod "B" učesnika povezanog na IP mrežu, ili obrnuto. U takvim situacijama, gejtvej obezbeđuje međusobno povezivanje Q-SIG i SIP na granici između PISN i IP mreže. Realizacija osnovnog interaktivnog poziva preko gejtveja specificirana je u Standardu ECMA-339 [10].

Drugi slučaj je kada Q-SIG poziv ili CISC, koji potiču od "A" učesnika povezanog na PISN, u okviru koje se koristi Q-SIG, prolaze preko IP mreže koristeći SIP, i završavaju kod "B" učesnika povezanog sa drugom PISN (ili drugim delom iste PISN), u okviru koje se koristi Q-SIG.

Standard ECMA-355 tretira navedeni slučaj, jer se prilikom takvog načina povezivanja sačuvaju sve mogućnosti Q-SIG u toku prolaza kroz IP mrežu [6]. To se postiže tunelovanjem, tj. enkapsuliranjem Q-SIG poruka unutar SIP zahteva i SIP odgovora, koji se razmenjuju u kontekstu propisanog SIP dijaloga. Ovakva se veza smatra "*end-to-end*" povezivanjem, a arhitektura za to se može postići korišćenjem gejtveja na svakom prelazu između PISN, koja koristi Q-SIG, i IP mreže, koja koristi SIP [6], kao što je to prikazano na slici 1.

Svaki gejtvej može da obezbedi međusobno povezivanje PISN i IP mreže, na način kako je to opisano u ECMA-339, tj. samo za uslugu osnovnog poziva-BC (*Basic Call*), kako je to specificirano u Standardu ECMA-143 [4]. Mnoge druge mogućnosti Q-SIG (podrška za dopunske usluge i dodatne mrežne usluge) su, kao vlasničke, specificirane u drugim standardima i specifikacijama karakterističnim za konkretnog proizvođača. Neke od tih dodatnih mogućnosti Q-SIG su pogodne za međusobno povezivanje sa SIP, dok druge nisu, pošto u SIP za to ne postoje odgovarajući elementi ili se pak te karakteristike u okviru SIP ostvaruju na način, koji nije kompatibilan sa Q-SIG.

Rešenje za takve situacije nađeno je u tunelovanju Q-SIG poruka kroz IP mrežu, tj. u njihovoj enkapsulaciji u okviru SIP poruka, tako da ne postoji mogućnost gubljenja delova Q-SIG kod pomenutog "*end-to-end*" povezivanja. U tom slučaju, jedan od dva gejtveja kreira SIP dijalog sa drugim gejtvejom, a SIP poruke u okviru tog dijaloga koriste se za enkapsulaciju Q-SIG poruka. Kroz upotrebu SDP opisanu u RFC 3264 [9], dijalog takođe uspostavlja sesiju u kojoj medijski tokovi, nose korisničke informacije (npr. govor) između dva Q-SIG gejtveja. U stvari, tada ta dva gejtveja funkcionišu kao Q-SIG *Transit PINX*, prenoseći Q-SIG poruke sa malom ili nikakvom modifikacijom.

Sa razmatranim rešenjem za tunelovanje, IP mreža obezbeđuje inter-PINX konekciju (IPC) između dva gejtveja, koji onda funkcionišu kao tranzitne PINX. Tunel koji obezbeđuje SIP za Q-SIG poruke deluje kao kanal za signalizaciju D_Q, a medijski tokovi funkcionišu kao kanali za korisničke informacije U_Q [11]. Slika 2 ilustruje ovaj koncept.

Svaka PINX se fizički povezuje sa interventnom mrežom preko interfejsa na referentnoj tački "C". Interventna mreža obezbeđuje fizičku IPC između referentnih tačaka "C" krajnjih PINX. Funkcije mapiranja, unutar svake od PINX, vrše mapiranje D_Q-kanala i U_Q-kanala u "Q" referentnoj tački preko jedne, ili više IPC ostvarenih u referentnoj tački "C".

Standard ECMA-336 specificira upotrebu funkcija mapiranja za slučaj kada je interventna mreža zasnovana na IP [11] i kada se koristi za uspostavu sledećih tipova IPC:

- za TCP konekciju, za prenos signalnih informacija i informacija o kontroli resursa [12] i
- za par UDP tokova, po jedan tok u svakom smeru, za prenos korisničkih informacija preko RTP [13].

Jedan inter-PINX link zahteva jednu TCP konekciju, za podršku D_Q-kanalu, i jedan par UDP tokova po U_Q-kanalu. Pored prenosa Q-SIG protokola, TCP veza je takođe potrebna za prenos informacija o kontroli resursa za uspostavljanje UDP tokova.

Ovaj standard podržava dva načina interkonekcije između krajnjih PINX: "Na zahtev" (gde se jedna TCP veza i par UDP tokova uspostavljaju na početku svakog poziva i brišu na kraju tog poziva) i "Polu-stalnu" (gde jedna TCP veza sa neograničenim trajanjem prenosi Q-SIG u ime više poziva). U slučaju takve interkonekcije, TCP veza može podržati nula, jedan ili više poziva u isto vreme.

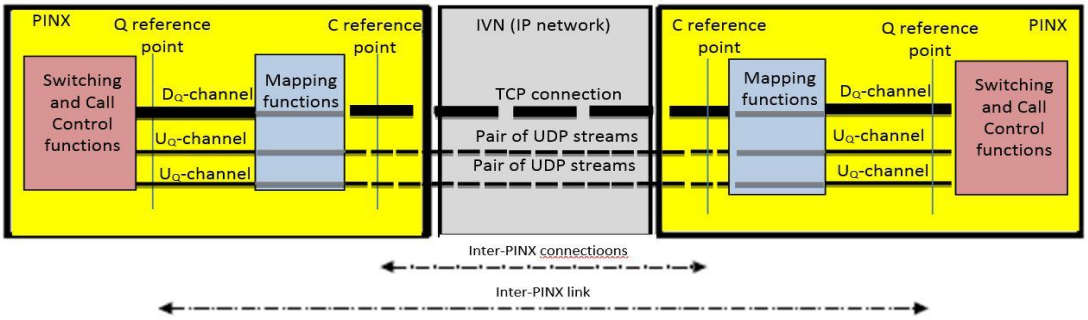
Par UDP tokova za korisničke informacije se uspostavlja na početku svakog poziva i briše se na kraju tog poziva [11].

III. PRIMENA TUNELOVANJA Q-SIG/SIP IP U OKVIRU PISN FUNKCIONALNOG KORISNIKA

Pod pojmom funkcionalni korisnik (FKo) podrazumeva se specifična organizacija koja, zbog svoje namene, ustrojstva, zadataka i teritorijalne razuđenosti, ima izuzetno velike zahteve u pogledu savremenih telekomunikacija, a pre svega za posedovanjem integrisanog sistema telekomunikacija za dovoljno brzu obradu i prenos tačnih i zaštićenih informacija.

Pri tome, odavno je postalo veoma važno da se kroz prenos i komutaciju informacija (govornih i negovornih) korisnicima u okviru takve organizacije ponudi široki spektar, najsavremenijih telekomunikacionih korisničkih usluga i mrežnih servisa, čiju tehničku podršku treba da pruži, ne samo na TDM već i na IP platformi, savremeno organizovana i funkcionalno orijentisana privatna telefonska mreža (PTN).

Kao takva, PTN razmatranog FKo treba da predstavlja jedinstvenu telekomunikaciono-informatičku platformu, te da po svojoj kompleksnosti, organizaciji, dostignutom stepenu tehničke integracije i geografskoj rasprostranjenosti koincidira ka performansama, odrednicama i standardima savremene



Sl. 2. IPC koncept (polu-stalna konekcija) [11].

korporativne telefonske mreže.

To onda znači, da nije potpuno zatvorena i okrenuta samoj sebi, već da se putem, različitih i geografski razuđenih, interkonekcija povezuje sa javnom fiksnom i mobilnim telekomunikacionim mrežama, kao i sa postojećom, funcionalnom, digitalnom, tranking, mobilnom radio-mrežom TETRA (*Terrestrial Trunked Radio*).

Treba reći da je Automatska telefonska mreža (AtlMr) razmatranog funkcionalnog korisnika kompleksna privatna mreža automatske telefonije, sa učešćem više desetina ISDN i IP orijentisanih PABX, povezanih po mešovitoj arhitekturi „zvezde“ i „petlje“ i višenivovski strukturiranih kao krajnje, čvorne, tranzitne i glavna tranzitna. Primenom Q-SIG, kao sistema CCS (*Common channel signalling*) orijentisane signalizacije, u toj AtlMr obezbeđena je interoperatibilnost između digitalnih automatskih telefonskih centrala (DATC) različitih proizvođača. To je postignuto u samoj fiksnoj telekomunikacionoj mreži funkcionalnog korisnika, zatim sa DATC iz drugih privatnih telekomunikacionih mreža (sa kojima je u interkonekciji), te i sa DATC javnih operatora fiksne i mobilne telefonije. Na taj način, obezbeđena je potpuna nezavisnost od različitih proizvođača ISDN DATC, kao i predviđeni obim osnovnih i dopunskih korisničkih usluga i mrežnih servisa, bez obzira na koji su komutacioni čvor priključeni. Pri tome, u vezi sa daljom primenom Q-SIG u ATlMr, za dotičnog funkcionalnog korisnika se nesumnjivo nameću prioriteti da se iste usluge i servisi realizuju, ne samo na njenim homogenim ISDN delovima, već i na delovima sa IP/SIP interventnim mrežama iz okvira Intraneta.

Odgovarajući na te obaveze, u poslednjih nekoliko godina osavremenjen je, ili potpuno zamenjen, određen broj čvornih i tranzitnih DATC, koje su postale interoperatibilne, na nivou IP/SIP, i sa izgrađenom IP mrežom za komutaciju paketa. Tu se prvenstveno misli na savremene komutacione sisteme, koji su posebno dizajnirani za rad u PISN uz interoperatibilnost sa IP/SIP okruženjem (PINX).

Praktično rešenje tunelovanja Q-SIG kroz IP proxy, primenom SIP/UDP, ostvareno je na delu ATlMr FKo na kome je povezivanje između učestvujućih tranzitnih PINX, realizovano snopom od 30 IP trankova preko LAN 10/100 Mb/s Etherneta. Učestvujuće krajnje ISDN PABX (DATC) povezane su na pripadajuće tranzitne PINX putem prenosničkih snopova od po 30 TDM trankova (sa E1/ISDN PRI) i sa primenom sistema mrežne signalizacije tipa Q-SIG.

Tranzitne PINX su izgrađene u arhitekturi Linijskih modula interfeja (LIM-ova) sa 7U magacinima, takozvanih *Media Gateway* LIM-ova, koji se sastoje od *Telephony Servera* i *Media Gateway*-a, bitnih za rad kako sa IP/SIP, tako i sa ISDN/Q-SIG okruženjem [15]. Ta verzija sistema komutacije pruža SIP ekstenzijama i SIP trankovima visok nivo funkcionalnosti, sa podrškom koja je u skladu sa više od 45 RFC standarda, kao osnovu za integraciju sa aplikacijama objedinjenih komunikacija trećih strana i organizaciju modernijih i efikasnijih poslovnih procesa, kao i za vezu sa spoljnim svetom putem SIP trankova (kao alternacija tradicionalnim PSTN mrežama) [15].

Primenjeni sistem je sertifikovan za veliki broj SIP mrežnih provajdera i odgovara SIP *Connect* 1.1 standardu. Njegov SIP tranking interfejs je takođe osnova za integraciju sa sistemima treće strane, kao što su *Microsoft Linc 2013/Skipe-for-Business, IBM Sametime SUT* i druge platforme za omogućavanje interoperatibilnosti između različitih komunikacionih platformi. Pored toga, sa ovim sistemom podržan je tip SIP tranka putem koga se vrši umrežvanje sa prenosom svih standardizovanih učesničkih i mrežnih usluga. To znači, da je na taj način omogućena i transparentnost funkcija između, njime povezanih, čvorova [15].

LIM se sastoji od jednog *Server*-a na koji, po potrebi, može biti povezano od jednog do petnaest *Media Gateway*-a, ali se u konkretnom slučaju radi o samo jednom *Media Gateway*-u po LIM-u. *Telephony Server*-i, kao osnovni delovi servera na obe tranzitne PINX, poseduju operativni sistem *Novells SUSE® Linux Enterprise Server (SLES)* verzije 11, sa 64-bitnom arhitekturom. Implementiran je server u obliku serverske ploče ASU-E (*Aastra Server Unit Ebedded*) sa poboljšanim performansama, koja je bazirana na *COMXpress* standardu u konfiguraciji sa: procesorom 2.26GHz Com2Duo, RAM 4GB (proširiva do 8GB), SATA HDD kapaciteta 160GB, podržanim SW RAID1 i 2 Eternet porta [16].

Media Gateway Unit je implementirana MGU2 ploča, koja u osnovnoj varijanti podržava do 4 interfejsa ISDN E1 (ili T1), mobilne lokale, IP lokale (H.323, SIP – uključujući IP DECT i WiFi), IP prenosnike i IP umrežavanje putem H.323 i SIP, te Q-SIG umrežavanje. Na svakoj učestvujućoj tranzitnoj PINX u LIM-u je implementirana po jedna MGU2 ploča, koja u

LIM kabinetima ima tačno određenu fizičku poziciju [17].

Osnovne komponente instaliranog *Media Gateway*-a su: TDM *Switch*, *Ethernet* (Layer 2) i *Media Stream Processor* (MSP).

TDM *Switch* na MGU2 ima centralnu funkciju za komutaciju svih medijskih veza između trankova, ekstenzija i pomoćnih funkcija, koje se prenose kroz njega. TDM *Switch* je neblokirajuće vremensko komutaciono polje (tipa: *Time-Space-Time*) za 2048 x 64kb/s vremenskih pozicija.

Na MGU2 ploči postoje dve standardne 10/100/1000 *Base-T* LAN veze označene sa LAN 0 i LAN 1. *Ethernet* paketi tipa "*Non-RTP*" za signalizaciju, se preko sviča Sloja 2 usmeravaju na procesor uređaja-DP (*Device Processor*), dok se "RTP" paketi koji prenose medije (VoIP), preusmeravaju na DSP u MSP.

MSP je sistem procesor za VoIP telefonske aplikacije i ujedno zajednička baza resursa koju dele sve DSP orijentisane funkcije vezane za MGU2, kao što su VoIP, T.38 i DTMF prijemnici [17].

RTP paketi [14], koji se šalju preko IP mreže, podložni su slučajnim varijacijama kašnjenja, dolasku van redosleda i riziku da budu odbačeni. Ovi negativni efekti smanjuju kvalitet prenošenog audio signala, pa se za ublažavanje tog efekta na MGU2 koristi kolo *Jitter Buffer*-a, koje tu aktivnost realizuje na račun povećanih kašnjenja kod prenosa govora. Duga kašnjenja kod prenosa govora, posebno u kombinaciji sa ehom na daljem kraju, čine da eho postane primetniji i uznemiravajući. Iako se za pokušaj minimizacije tog kašnjenja koristi ugrađeni poništavač eha, mora se imati u vidu, da na njegov rad može imati negativan uticaj situacija kada dođe do smanjenja kvaliteta govora (npr. zbog gubitka paketa) [17].

Ugrađeni poništavač eha EC (*Echo Canceler*) uklanja eventualno postojeći eho predajnog signala (povratni signal), iz prijemnog signala. Eho je obično uzrokovan refleksijama koje se javljaju kod 2/4-žičnog prenosa, ali i kao akustični eho u telefonskim aparatima. EC se koristi samo za pozive preko IP mreže, koja radi u režimu sa komutacijom paketa (VoIP).

Važno je napomenuti da je konfiguracija EC takva, da postoji samo jedan na MGU2 ploči, pa tako utiče na sve VoIP pozive u njoj, uključujući i inter-Media GW pozive preko IP-a. Prema tome, prilikom testiranja izbor podešavanja EC morali smo realizovati kao kompromis, u smislu izrečenog [17].

Za sve odlazne RTP (audio) media tokove, pri VoIP pozivu, MGU2 kreira slučajnu 32-bitnu vrednost SSRC (*Sinchronization Source*). Ova vrednost se koristi za sve RTP pakete u tom toku, sve vreme dok je on aktivan. Ako se uspostavljeni poziv stavi na čekanje, ili se izvrši bilo koja promena trenutno aktuelnog RTP media toka od strane sistema komutacije (npr. promena DTMF relejnog režima), aktuelni media tok se zatvara i zamenjuje novim, sa novom SSRC vrednošću.

Na odgovarajućem dolaznom RTP media toku, MGU2 potvrđuje sve primljene RTP pakete. Paketi sa bilo kojom SSRC vrednošću će biti prihvatani sve dok se primaju parovi paketa sa uzastopnim brojevima i istim SSRC [17].

Glavne funkcije implementirane MGU2 ploče su sledeće: posreduje u svim komunikacijama ka komutacionom sistemu; poseduje interfejse za digitalne trakove E1/T1; obezbeđuje RTP/SRTP, DTMF detekciju, DTMF i faksimil tonove preko RTP; otklanja eho i smanjuje džiter u VoIP komunikaciji [17].

Prilikom implementacije MGU2 ploče u sistem provodi se procedura inicijalizacije njegovih funkcija kao Media Interfejsa (važne su za RTP podatke u medija tokovima) i kao Signalizacionog GW-a (važan za manipulaciju sa Q-SIG porukama). U tom smislu, prijavljuju se njegova IP adresa *Default* GW-a, zatim IP adresa Media Interfejsa i IP adresa Signalizacionog GW-a [17].

Primenjeni Sistem komutacije podržava, kako IPv6, tako i IPv4 adresiranje, pa u konkretnom rešenju PINX rade kao izvorna IPv4 mreža za Menadžere poziva i komponente GW-a. Pri tome, platforma HV i OS softver rade koristeći IPv4 "*dual stack*" interfejse za IP mrežu. Softverske komponente elemenata (Menadžer poziva i GW) konfigurisani su za obavljanje i međusobno korišćenje standardnog IPv4 adresiranja, kako iz perspektive signalizacije, tako i iz perspektive medija. Instalirana je inter-Server komunikacija IPv4 "*dual stack*", tako da ceo sistem (svi serveri) koristi istu IP verziju. IPv4 adrese, iz 32-bitnog opsega izvorne IP mreže, podržane su za SIP terminale, SIP klijente i SIP trankove. *Media Server* podržava i IPv4 i IPv6 za medijske tokove (RTP i RTCP) i upravljanje odlaznim pozivima (SCTP). Pošto MGU2 i *Media Server* podržavaju IPv4, to onda ne ometa primenu mera bezbednosti (zaštitu signalizacije) u sistemu [17].

Interventna mreža je realizovana putem sopstvenog IP proxy, koji je izveden na bazi 26-to portnih 10/100 *Base-T Ethernet CISCO* svičeva tipa SQ200-26pp, na oba kraja, i sa spojnim putem kroz 10/100 *Base-T Ethernet* kapacitet Optičkog digitalnog sistema prenosa brzine 625 Mb/s, a po kojima se takođe koristi SIP.

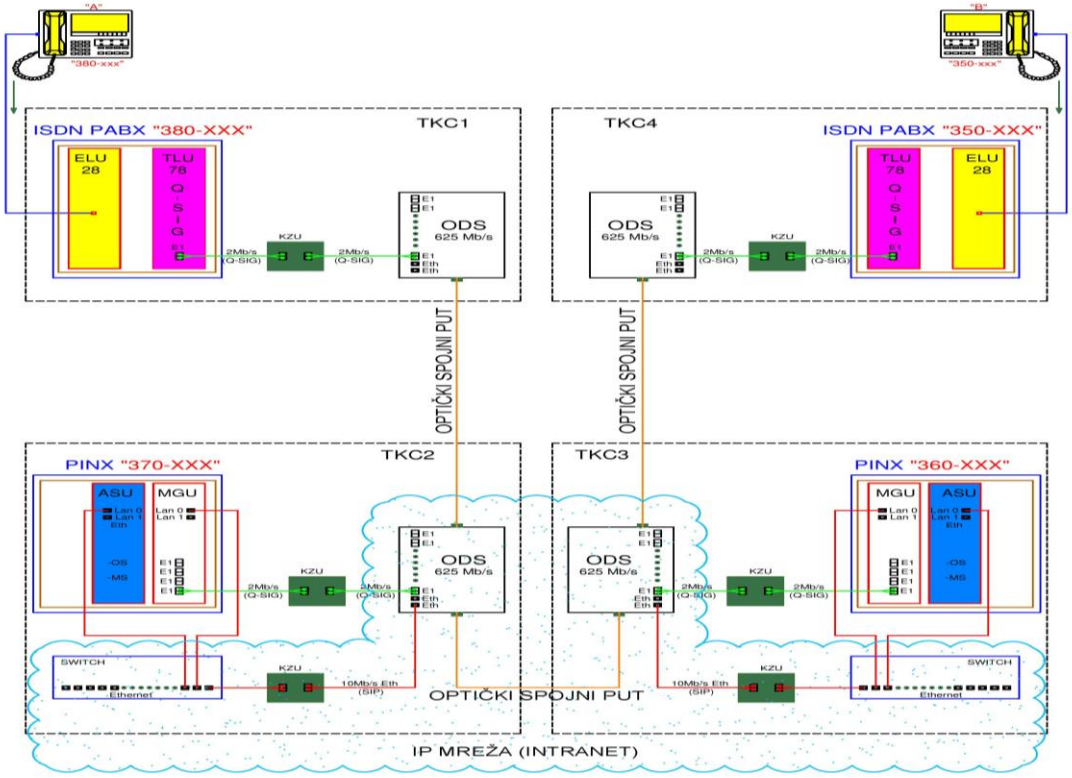
Tako izgrađena arhitekura dotičnog dela AtlMr FKo dala je hardversku i softversku mogućnost za realizaciju neophodne TCP konekcije i tunelovanje Q-SIG kroz IP proxy, između tranzitnih PINX (sa TKC2 i TKC3) u kojima su integrisani *MediaServeri* i *Media GW*-i, a u svrhu odvijanja mrežnog telefonskog saobraćaja kroz novoformirani SIP prenosnički snop od 30 trankova (vidi sliku 3).

Prvi korak, posle nabavki i instaliranja neophodnih softverskih licenci za SIP rutu i proračunati broj SIP trankova u njoj, manjih intervencija u Planu analize cifara i biranja-NADAP (*Number Analysis Dialing Plane*), te fizičkog ostvarenja svih potrebnih konekcija na testiranoj opremi, bio je da se na propisani način (na obe tranzitne PINX) definišu i iniciraju **nove SIP rute**. To je ostvareno preko postojećeg *Sistem Manager*-a i aplikativnog softverskog paketa PUTTY tako, što je softverski formiran i iniciran novi prenosnički snop, kapaciteta 30 SIP trankova (sa protokolima TCP za signalizaciju i UDP za media tokove), te na isti usmeren relevantni deo mrežnog telefonskog saobraćaja (odlazni pozivi iz lokalnog okruženja ili iz tranzita).

Za administriranje specifičnih podataka o **novoj ruti sa SIP trankovima** korištena je komanda "**sip_route**". Novi podaci korišćeni su, kao dopunski, uz već ranije korišćene podatke za

definisanje tradicionalnih ruta (ISDN, digitalnih, analognih...).

Kada se definiše **nova SIP ruta** i u okviru nje formira prenosnički snop potrebnog kapaciteta **SIP trankova**, prvo se koriste naredbe "**sip_route-set**", pa onda "**ROCAI**", "**RODAI**" i "**ROEQI**", te na kraju "**RODDI**". Način realizacije definisanja **nove rute** i podizanja **SIP trankova** u okviru nje, obavlja se u 5 osnovnih koraka i to:



Sl. 3. Realizacija tunelovanja Q-SIG/SIP IP na delu ATIMr funkcionalnog korisnika

1. sip_route -set [-**profile** <ime profila trunk-a] -**route I** -**uristring0** "**sip:? @** <SIPrekURI>", [ostali parametri sip_ route potrebni ili zahtevani profilom - Parametri koje uključuju -**Profile** -].

2. ROCAI: ROU = I, SEL= SIG = {D11 = **A** za SIP rutu}, ostali servisni parametri.

3. RODAI: ROU = I, TIPE = TL66, VARI = 00000000, VARC = 00000000, VARO = 00000000; Ako je **sip_route -profile** postavljen, onda VARI, VARC, VARO moraju imati nule. Ako nije tako, onda se ova konfiguracija postavlja iz profila navedenog kao -Profil parametri linijskog protokola-.

4. ROEQI: ROU = I, TRU = <lim> - <prvi redni broj> && <lim> - <poslednji redni broj>. TRU parametar definiše LIM-ove i kapacitet koji se koriste za SIP signaliziranje na ovoj ruti. (Napomena: Komanda "**sip_ rute**" mora biti izvršena pre "**ROEQI**" koja povezuje opremu sa rutom).

5. RODDI: ROU = I, DEST = <dest-number>. Definišu se pristupni, jednoznačni i dvoznačni kodovi, tzv. destinacije, koje se, prilikom odlaznih poziva, usmeravaju na ovu rutu.

Znači, uz administriranje podataka specifičnih za SIP trankove, tradicionalno se administriraju i "RO" podaci o ruti. U okviru naredbe "**sip_route-set**", na obe tranzitne PINX, definisane su i inicirane **nove rute sa SIP**, uz uvodenje sledećih parametara: **route**=25 (ruta je dobila svoj broj); **protocol** = udp (uveden je *Default*-ni UDP protokol); **profile** =*Default* (postavljen je difoltni profil, pošto se ruta uspostavlja između PINX istog tipa i proizvođača, a radi što bolje saradnje između njih); **service**=*PRIVATE* (parametar je uslovljen postojećom licencom za rad centrale u privatnoj mreži); **uristring0**=sip:?@192.168.X.X (definisane su IP adrese PINX na oba kraja veze komunikacije, a **uristring0** se koristi kod kreiranja poruke "*request URI*" u okviru SIP zahteva (recimo *INVITE*) po tipu: "nepoznati javni broj"); **remoteport**=*default* (radi se o "*Remote host port*-u" čiji se rang proteže od 0 do 65535; vrednost *default*=5060 definiše da je paketski protokol TCP/UDP); **accept**=ALL (Tip podudaranja koji treba da se izvrši prilikom upravljanja pozivima. Vrednost je definisana kao ALL= "prihvati sve pakete"); **priority**=255 (Prioritet prilikom uparivanja podataka dolaznih poziva rute je 0-255, najniži prioritet = 255. Obzirom da je parameter **accept**=ALL, to onda uslovljava da se prioritet mora postaviti na *Default*-nu vrednost 255); **register**=NO_REG (postavljena je takva vrednost, pošto relevantna PINX nema udaljene LIM-ove); **trusted**=*NO_TRUSTED* (Parametar je vezan sa parametrom **profile**=*Default*. SIP ruta prema pouzdanoj mreži, poverava odredište rute uz ograničenje strane porekla informacije.); **challenge**=no (Izazov za dolazni *INVITE* zahtev na ovom prenosničkom snopu. Definisano je "ne", pošto prenosnički snop na ovoj ruti ima prirodu *EMERGENCY*.);**supervise** =

NO_SUPERVISION (Definisano je da se ne vrši supervizija SIP poruka, t.j da opcije slanja paketa signalizacije ne čekaju na poruku "200ok", kao odgovor druge strane); **codecs**=G723,G729A,G729AB,PCMA,PCMU;**handleasexn** = no (Ova postavka se koristi da omogući korišćenje trank podataka za ekstenzije dolaznih poziva. Od broja polja pa na dalje treba da se podudara sa (pre) registrovanom ekstenzijom. Format je "da" ili "ne". Definisano je"ne".).

Testiranim rešenjem se kao prelazi, između delova PINS koje koriste ISDN/Q-SIG (krajnje PINX na TKC1 i TKC4), i IP mreže, koja radi po SIP (Intranet kao IVN), koriste GW-i (*Media GW*-i iz sastava tranzitnih PINX na TKC2 i TKC3).

Scenario realizovanog povezivanja krajnjih ISDN PINX, putem tunelovanja Q-SIG preko IP/SIP u privatnoj ATlMr funkcionalnog korisnika, prikazan je na slici 3. To je situacija, nastala na delu ATlMr FKo, koja se u potpunosti poklapa sa standardnom situacijom prikazanom na slici 1.

Na taj način, Q-SIG poziv koji je iniciran od "A" učesnika povezanog na PINX numeracije "380-xxx" sa TKC1, koja koristi Q-SIG na prenosničkom snopu prema tranzitnoj PINX sa TKC2, prolazi kroz tranzitnu PINX i njen *Media GW* (igra ulogu Ulaznog GW), koji po redu enkapsulira Q-SIG poruke u SIP (kroz TCP za signalizaciju i UDP za medija tokove), a zatim primenom tunelovanja Q-SIG prelazi preko IP mreže, koja koristi SIP, do druge tranzitne PINX sa TKC3, gde se na njenom *Media GW* vrši prevođenje SIP u Q-SIG (igra ulogu Izlaznog GW), te završava na učesniku "B", povezanom na krajnju PINX numeracije "350-xxx" sa TKC4, koja koristi ISDN/Q-SIG (na prenosničkom snopu za povezivanje sa tranzitnom PINX na TKC3).

Testiranim rešenjem je postignuto da, po pitanju prenosa osnovnih i dopunskih korisničkih usluga i svih mrežnih usluga (kao i posebnih *Mitel "proprietary"* usluga), ne postoje ograničenja kako u smislu kompatibilnosti Ulaznog i Izlaznog GW, tako i u smislu Q-SIG mogućnosti i ekvivalenata SIP IP mreže, te nema gubljenja delova Q-SIG na prikazanom "*end-to-end*" povezivanju.

Putem tunelovanja Q-SIG, IP mreža obezbeđuje inter-PINX TCP konekciju između dva *Media GW* iz sastava tranzitnih PINX, kada tunnel koji SIP obezbeđuje za prenos Q-SIG poruka deluje kao DQ-kanal za signalizaciju, dok uspostavljeni UDP media tokovi funkcionišu kao UQ-kanali za prenos korisničkih informacija (govora, modemskih informacija, podataka i sistemskih poruka).

Na uspostavljenom SIP prenosničkom snopu realizovana je i uspešna spoljna-vansistemska zaštita informacija, kako svih prenešenih signalizacionih kriterijuma iz okvira Q-SIG, tako i svih korisniških informacija koje se prenose kroz medija tokove. Za to su upotrebljeni uređaji za grupnu zaštitu IP/SIP paketskog prenosa, na nivou 10/100Mb/s *Base-T Etherneta*, koji su montirani sa obe strane prenosničkog SIP snopa, tj. na TKC2 i TKC3 (slika 3). Tako je postignuta neophodna neprekidnost zaštite informacija na celom spojnom putu od ISDN PABX "380-xxx" sa TKC1, preko tranzitnih PINX "370-xxx" i PINX "360-xxx" sa TKC2 i TKC3, do ISDN PABX "350-xxx" sa TKC4.

IV. ZAKLJUČAK

Realizovano rešenje za organizaciju telefonskog saobraćaja na delu ATlMr FKo povezivanjem dve tranzitne PINX putem organizacije **SIP prenosničkog snopa**, kroz **vlastitu IP mrežu** (*Intranet*), predstavlja novinu u organizaciji PTN razmatranog funkcionalnog korisnika. Korišćenje, od ranije primenjenog i u praksi dokazanog, sistema mrežne signalizacije tipa Q-SIG, putem njenog tunelovanja i prenosa bez degradacije kroz IP mrežu sa SIP protokolom, doprinelo je da se u ATlMr FKo ne naruši od ranije **izgrađeni status PINS**, i na delovima gde se njeni TDM/ISDN delovi povezuju sa IP proxy. Ovakvo rešenje je **uslovljeno** veličinom ATlMr i potrebnim finansijskim sredstvima, tj. nije bilo moguće realizovati jednovremenu tranziciju kompletne postojeće privatne telefonske mreže na bazi komutacije kola u mrežu sa komutacijom paketa, pri čemu su **zadržane** sve njene postojeće performanse.

Abstract

This paper explains a new way of connecting ISD and IP oriented PABX in a Private automatic telephone network (ATN) of integrated services for private users (PINX), by performing network Q Signalization (Q-SIG) tunneling through their private SIP oriented IP network (Intranet). It also shows as to how an ECMA-355 standard utilized Q-SIG tunneling through IP/SIP and describes a practical solution, realized within the ATN integrated services of the private integrated services network (PINS SM) for interconnecting users from differing end ISDN/Q-SIG PABX, through transit IP/Q-SIG PINX (the IP/SIP network performs the role of an Intervening network-IVN).

Q-SIG over SIP Tunneling in PISN with Integrated Services of Functional User

Роминг у 802.11 мрежама и његова експериментална карактеризација

Данило Лазовић, Зоран Станковић, Јован Бајчетић,

***Апстракт*— Главни циљ овог рада је приказ основних принципа експерименталне карактеризације бежичних рачунарских мрежа. Развој метода и поступака мерења и анализе мерених резултата који се односе на праћење роминг догађаја клијента мреже и његовог утицаја на пакетски пренос података у IEEE 802.11 мрежном окружењу. У складу са тим, полазећи од неких постојећих решења за мерење handoff интервала, комбинацијом, надоградњом и прилагођењем реалним условима у мрежи, развијен је и примењен поступак мерења и анализе резултата који се односи на идентификацију, основну карактеризацију роминг догађаја и праћење његовог утицаја на перформансе пакетског преноса у реалном окружењу IEEE 802.11 мреже што је и главни допринос овог рада.**

***Кључне речи*— 802.11 мреже, роминг процес, handoff интервал, мерење пакетског протока мреже.**

I. УВОД

Поступци за мерење handoff интервала су до сада представљени у разним саопштењима – у лабораторијским условима [1, 2], као и у реалним условима [3]. У експерименталној поставци [1, 2] су коришћена два AP (Access Point) уређаја, станица за надгледање саобраћаја и референтна станица која је вршила роминг (прелажење из одговорности једног у одгорворност другог AP-а) између та два уређаја, док се код реалне архитектуре једне 802.11 мреже [3] користило више AP уређаја, станица за надгледање саобраћаја и референтна станица која је вршила роминг између AP уређаја. Мерени резултати који су добијени у тим радовима су били у складу са очекиваним резултатима који су доступни у литератури.

Полазећи од метода мерења handoff интервала изложених у [1-3], њиховом комбинацијом, надоградњом и прилагођењем у односу на расположиву опрему и услове и ограничења која су евидентирана у једном реалном роминг окружењу попут 802.11n мреже Електронског факултета у Нишу, развијен је поступак намењен експерименталној карактеризацији роминг догађаја у Wi-Fi мрежи са већим бројем AP уређаја.

Предложени поступак има следеће особине:

1. Поступак је развијен са намером да се омогуће мерења у реалним (не-лабораторијским) условима Wi-Fi мреже са већим бројем AP уређаја;
2. Поступак омогућава добијање информација о времену и месту настанка роминг догађаја, трајању handoff интервала и нивоима сигнала AP уређаја у току роминг догађаја, затим праћење на ком каналу у 2.4 GHz ISM опсегу клијент комуницира пре, током и после роминг догађаја, идентификацију области у сервисној зони мреже у којој се приликом задате трасе кретања дешавају роминг догађаји (роминг области), као и мерење параметара пакетског преноса података пре, за време и након роминг догађаја.
3. Предложене мерне процедуре могу да се релативно лако прилагоде професионалној опреми као што су специјализовани мерачи нивоа EM поља, Wi-Fi тестери, сензори за позиционирање унутар просторије и слични уређаји, са циљем да се добију резултати високе тачности који би били од великој значаја за ефикасну анализу рада Wi-Fi мреже.

Рад је реализован кроз шест поглавља. Након увода, у другом поглављу је представљен handoff интервал. Треће поглавље даје начин на који су се реализовала мерења, четврто поглавље представља поступак експерименталне карактеризације роминга у IEEE 802.11 мрежама. У петом поглављу су представљене особине саобраћаја које су мерене на „Траси 1“. Закључак је дат у шестом поглављу.

II. HANDOFF ИНТЕРВАЛ

Ради реализације процедуре роминга (handoff процес), мобилна станица размењује са приступном тачком (AP) уређене секвенце порука. Физички слој два AP уређаја омогућава повезивање овог логичког механизма и шаље информације о стању пареметара уређаја са једне инстанце на другу. Пренос на нивоу битова који обављају најмање три учесника – мобилна станица, претходни AP уређај и наредни AP уређај у потпуности се реализује коришћењем функција физичког слоја (Сл. 1). Претходни AP уређај је AP уређај са којим је мобилна станица имала везу пре извршења handoff-a, а AP уређај са којим је мобилна станица остварила комуникацију након handoff-a назива се наредни AP уређај.

Процес handoff-a се спрводи у две фазе [3]**:**

1. Откривање AP уређаја у окружењу и
2. Поновно придруживање.

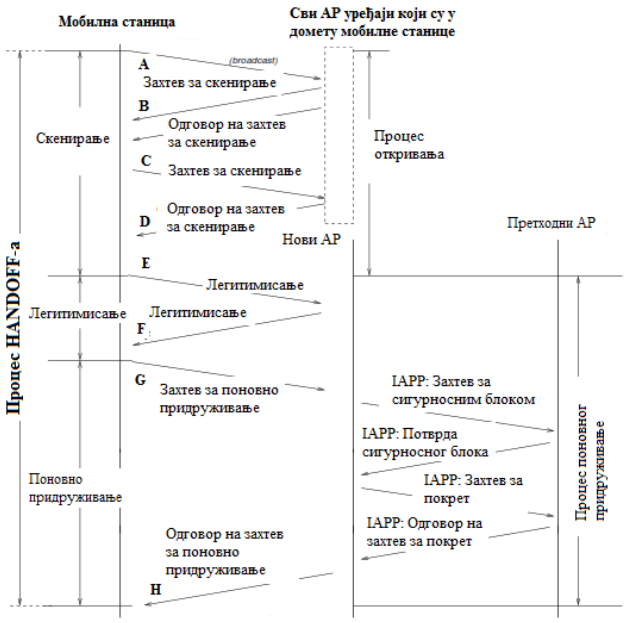
Јован Бајчетић, Војна академија, Универзитет одбране у Београду, Павла Јуришића Штурма 33, 11000 Београд, Србија (e-mail: bajce05@gmail.com).



Сл. 1. Процес HANDOFF-а

Од самог произвођача Wi-Fi опреме зависе разлози због којих мобилна станица мења АР уређај на који је тренутно повезана. Ови разлози могу да буду изазвани различитим променама каракетристика преноса и стања пријемног сигнала које открива мобилна-пријемна станица. Најчешћи разлози за handoff одлуку су следећи [4]:

1. Низак ниво сигнала са АР уређаја на који је повезана мобилна станица (најчешћи ниво сигнала после којег мобилна станица мења АР уређај и који може да се у литератури нађе за поједине мрежне уређаје износи око -70 dBm);
2. Мобилна станица детектује веома лош однос сигнал-шум што се тиче сигнала који се прима са АР уређаја на који је повезана мобилна станица;
3. Велики број изгубљених рамова података у комуникацији мобилне станице са АР уређајем. Рамови се шаљу, али за њих не стиже потврда о успешном пријему путем АСК рама;
4. Мобилна станица изгуби конекцију са тренутним АР уређајем због неког техничког проблема.

III. Експериментална карактеризација роминга у IEEE 802.11n мрежи Електронског факултета у Нишу

Експериментална карактеризација роминга у IEEE 802.11n мрежи Електронског факултета у Нишу обухватила је мерење особина пакетског саобраћаја између мобилне станице која врши роминг и АР уређаја који учествују у роминг процесу. У оквиру ове активности вршена су мерења брзине преноса сегмената транспортног слоја мреже (протока TCP сегмената) током кретања мобилне станице, као и мерење броја изгубљених сегмената које шаље мобилна станица.

У оквиру локације дефинисана је једна траса кретања мобилног корисника са таквим простирањем које обезбеђује појаву бар једног роминга. У нивоу приземља факултета дефинисана је траса под називом “Траса 1 - приземље.

A. IEEE 802.11n мрежа Електронског факултета у Нишу

У згради Електронског факултета у Нишу где је постављена архитектура IEEE 802.11 мреже која омогућава извршење роминга извршена су сва мерења која се односе на експерименталну карактеризацију роминга у IEEE 802.11n мрежи. Мрежа која се налази у згради назива се ELFAK-INTERNET и састоји се од више АР уређаја који су распоређени на тачно одређеним локацијама у згради (приземље, М1 и по спратовима). Распоред АР уређаја дат је на Сл. 2. Четири АР уређаја се налазе у приземљу факултета у холу, још четири АР уређаја се налазе у три амфитеатра (Сл. 2). Уређаји произвођача Ubiquity Networks модел UniFi Access Point (2.4 GHz) се користе у 802.11 мрежи у приземљу, осим АР уређаја у амфитеатру А1. У амфитеатру А1 су инсталирана 2 АР уређаја истог произвођача, али напреднијег модела – UniFi Access Point - AC (2.4 GHz и 5 GHz).

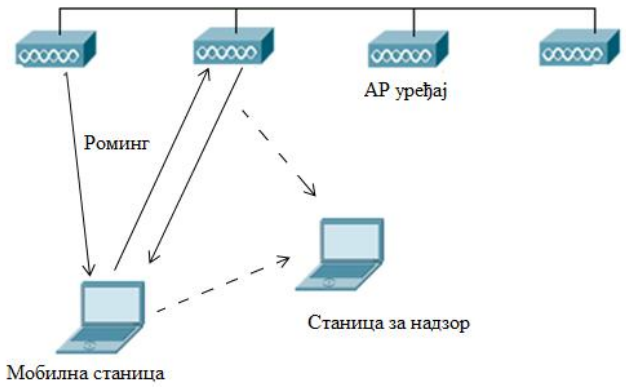
SSID који је идентичан називу целе мреже (ELFAK-INTERNET) имају сви АР уређаји. Приликом повезивања на факултетску мрежу клијент добија IP адресу коју задржава приликом вршења роминга, тако да се сви роминг процеси врше искључиво на слоју везе података (слој 2). Рамови из слоја везе података и информација о MAC (Media Access Control) адресама клијента и АР уређаја са којим клијент комуницира користили су се за идентификацију роминг догађаја приликом мерења која су се односила на експерименталну карактеризацију роминга.

Сл. 2. Распоред АР уређаја на приземљу факултета

IV. Мерни систем за експериментаљну карактеризацију роминга у IEEE 802.11n мрежи и поступак мерења

У циљу експерименталне карактеризације роминга у IEEE 802.11n мрежи Електронског факултета у Нишу користио се мерни систем који се састојао од два мобилна лаптоп рачунара који су у себи имали уграђене IEEE 802.11n мрежне адаптере и на којима су били инсталирани одговарајући софтвери за надгледање саобраћаја на слоју везе података и транспортном слоју (Сл. 3). Први рачунар је представљао клијента – мобилну

станицу, док је други коришћен за надгледање саобраћаја на мрежи и прикупљање података са исте (Станица за надзор, Сл. 3).



Сл. 3. Архитектура мерног система

A. *Мобилна станица*

Мобилна станица се након везивања на ELFAK-INTERNET мрежу кретала изабраним трасама, генерисала пакетски сабраћај ка Интернету и при томе улазила у процес роминга у одређеним областима трасе. Саобраћај мобилне станице се у току кретања надгледао и прикупљао од стране рачунара за надзор у циљу мерења handoff интервала и особина пакетског сабраћаја мреже приликом роминг догађаја. Као мобилна станица је коришћен лаптоп рачунар марке FUJITSU на којем је инсталиран Windows 8.1 Pro, 2,3 GHz са 6 GB RAM који у себи има интегрисану мрежну картицу.

Прикупљање и снимање размене пакета (пакетски саобраћај) између мобилне станице и AP уређаја је вршено уз помоћ програмског пакета WireShark, програмског пакета Acrylic WiFi Professional, и програмског пакета Matlab.

B. *Рачунар за надзор саобраћаја на мрежи*

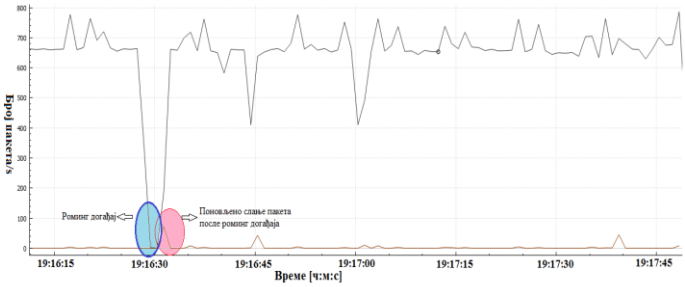
Основни задатак рачунара за надзор саобраћаја на мрежи (станица за надзор) је био да прикупи и сними целокупну размену рамова у слоју везе података између мобилне станице и AP уређаја на који је мобилна станица везана. Рачунар који је коришћен као мониторинг рачунар је био преносни рачунар марке Dell Vostro 1540 на којем је инсталиран Windows 7 Ultimate, 2,4 GHz и 4 GB RAM меморије који у себи има интегрисану мрежну картицу Broadcom 802.11n Network Adapter и Microsoft Virtual WiFi Miniport Adapter.

У свим сценаријима, рачунар за надзор је коришћен заједно са мобилном станицом која је вршила генерисање саобраћаја и снимање њеног пакетског саобраћаја према Интернету и при томе улазила у извршења роминг процеса. Овај рачунар се налазио непосредно поред мобилне станице и кретао се истом трасом и по истим условима као и мобилна станица. Апсолутно време на оба рачунара је постављено да буде идентично. На рачунару за надзор мреже је био активиран софтвер CommView for WiFi.

C. *Поступак мерења*

Поступак мерења на изабраној локацији у циљу експерименталне карактеризације роминга у IEEE 802.11n мрежи Електронског факултета у Нишу детаљно је описан у [5].

Анализом пакетског саобраћаја између мобилне станице и AP уређаја на транспортном нивоу који је снимљен приликом његовог кретања на траси одређује се зависност протока од временског положаја корисника на траси и уочава се повезаност временског тренутка роминг догађаја са временским интервалом у коме проток драстично пада. Типичан пример зависности броја пренетих пакета од временског положаја корисника на траси дат је на Сл. 4. На истој слици је браон бојом представљено поновно слање пакета (ретрансмисија) након што мобилна станица изврши процес роминга.



Сл. 4. Типичан пример зависности броја пренетих пакета и поново послатих пакета од временског положаја корисника на траси у условима интезивног саобраћаја

На Сл.4 се може уочити драстичан пад протока TCP сегмената непосредно пре него што мобилни клијент изврши роминг и нагло повећање броја пакета који су поново послати одмах након што мобилни клијент заврши роминг. Ово се објашњава тиме да је пре него што је клијент извршио роминг он дошао у просторну област (роминг област) где је сигнал AP уређаја на који је клијент везан веома слаб (ко што је већ претходно речено ниво сигнала AP уређаја пада испод -70 dBm). При тим вредностима сигнала долази до губитка рама у слоју везе података (рамови се шаљу, али се због лоше бежичне везе за њих не добијају ACK рамови потврде о њиховом успешном пријему). Пошто сваки изгубљени рам података носи у себи инкапсулиран IP пакет, а сваки пакет носи у себи TCP сегмент, тиме се проузрокују и губици у преносу TCP сегмената. Након што клијент изврши роминг и успостави стабилну конекцију са другим AP уређајем, поново се шаљу TCP сегменти који су изгубљени у преносу непосредно пре роминга.

V. Мерење особина саобраћаја током извршења роминга на траси "Траса 1 - Приземље"

У првом мерењу особина мреже, мобилни корисник се кретао од тачке А ка тачки Б (Сл. 5). Са Сл. 6. се може уочити да је број пренетих пакета у јединици времена стандардан у току целе трасе кретања са појединим пиковима када је сам број пренетих пакета био висок.

Сл. 5. Деоница на којој је вршено мерење особина мреже на „Траси 1- Приземље“

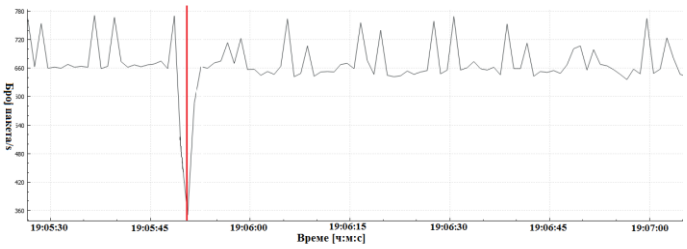
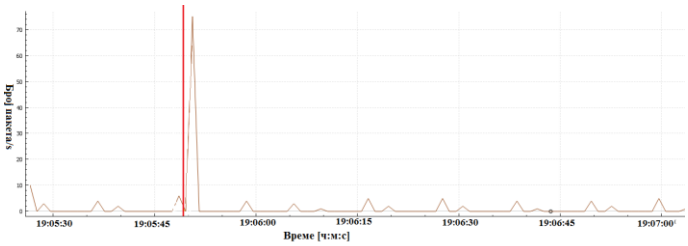
Сл. 6. Размена рамова између мобилне станице и АР уређаја који одговара роминг догађају T1_RD1, пролаз на траси AB1

На основу мерења реализованих у софтверском пакету CommView for WiFi који су приказани на Сл. 6. може се јасно видети да је у времену од 19:05:50,310420 до 19:05:50,748026 дошло до значајне деградације броја пренетих пакета. На ову деградацију броја пренетих пакета је утицало то што је мобилна станица ушла у процес извршења роминга, тј. мобилна станица је уместо сигнала са претходног АР уређаја почела да користи сигнал са другог АР уређаја (F0:9F:C2:2A:0A:7C). Тренутак у којем је дошло до преласка са једног на други АР уређај је обележен црвеном линијом, просечан број пренетих пакета у јединици времена је износио 685 пакета/s. (Сл. 7)



Сл. 7. Број пренетих TCP пакета у јединици времена приликом кретања на траси AB1, где је уочен роминг саидентификатором роминга T1_RD1 на „Траса 1- приземље“



Сл. 8. Број поново послатих пакета у јединици времена приликом проласка на траси AB1, где је уочен роминг са идентификатором роминга T1_RD1 на „Траса 1- приземље“

Током мерења карактеристика саобраћаја пажњу нам је привукао и податак који се односи на број поновно послатих рамова у току једног мерења од тачке А ка тачки Б и у супротном смеру (Сл. 8). Када се погледа број поновно послатих пакета, јасно се уочава чињеница да је овај број висок у тренуцима након што је укупан проток пакета саобраћаја јако низак. Другим речима, примећује се да у временском интервалу непосредно пре роминг догађаја укупан број пренетих пакета у јединици времена (проток пакета) непосредно нагло опао да би се одмах након роминга опоравио и вратио на просечну вредност од око 685 пакета/s. Са друге стране, одмах након роминга, број пакета који су поново послати у јединици времена нагло расте, што траје кратак временски период, а онда се поново враћа на малу вредност након роминга. Ово се објашњава губитком рамова података, а самим тим и TCP сегмената непосредно пре роминга (због ниског нивоа сигнала базног АР уређаја) и за време роминга (због прекида слања рама података у handoff интервалу).

У другом мерењу особина мреже кретали смо се од тачке Б ка тачки А (Сл. 5). Са Сл. 10 се може уочити да је број пренетих пакета константан из разлога што се тачка Б налази у амфитеатру А1, па је и сам ниво сигнала са АР врло висок. Током реализације другог мерења такође смо се кретали брзином од 3 km/h.

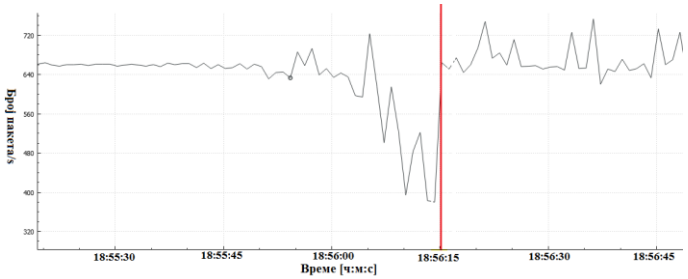
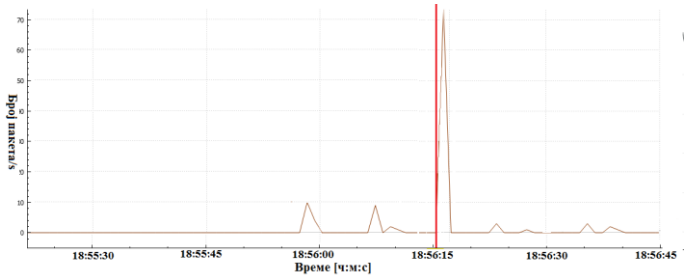
Сл. 9. Размена рамова између мобилне станице и АР уређаја који одговара роминг догађају T1_RD4, пролаз на траси BA2

Како се прилази тренутку роминга, број пренешених пакета је почиње да опада. На основу мерења реализованих у софтверском пакету CommView for WiFi који су приказани на Сл. 9 може се јасно видети да је у времену од 18:56:16,072077 до 18:56:16,163529 дошло до тога да је мобилна станица ушла у процес извршења роминга, тј. мобилна станица је уместо сигнала са АР уређаја (26:A4:3C:BB:D8:D3) почела да користи сигнал са

другог АР уређаја (F0:9F:C2:2A:09:2A). Временски тренутак у којем је дошло до преласка са једног на други АР уређај је обележен црвеном линијом, просечан број пренетих пакета у јединици времена (проток) у току мерења у условима интезивног саобраћаја је износио 615 пакета/s. (Сл. 10).



Сл. 10. Број пренетих TCP пакета у јединици времена приликом кретања на траси BA2, где је уочен роминг са идентификатором роминга T1_RD4 на „Траса 1- приземље“



Сл. 11. Број поново послатих пакета у јединици времена приликом проласка на траси BA2, где је уочен роминг са идентификатором роминга T1_RD4 на „Траса 1- приземље“

Број поново послатих пакета у току мерења од тачке Б ка тачки А је значајан у тренутку након извршења роминга (Сл. 11). У складу са пртходном дискусијом, овакав податак је очекиван због тога што у периоду непосредно пре одлуке о вршењу роминга мобилна станица због лошег сигнала почиње да губи рамове података (нема потврде за послате рамове), а самим тим и TCP сегменте. Када мобилна станица успостави сигурну комуникацију са новим АР уређајем и изврши се оговарајућа размена порука између претходног и новог АР уређаја, тада се тек може поновити слање пакета који су изгубљени.

VI. ЗАКЉУЧАК

Мерењем карактеристика пакетског саобраћаја у транспортном слоју уочен је драстичан пад протока TCP сегмената непосредно пре него што мобилна станица изврши роминг и нагло повећање броја пакета који су поново послати одмах након што мобилна станица заврши роминг процедуру. Ово се објашњава тиме да је пре него што је мобилна станица извршила роминг, мобилна станица дошла у просторну област (роминг област) где је сигнал АР уређаја на који је клијент везан веома слаб (ко што је већ претходно речено ниво сигнала АР уређаја пада испод -70 dBm). При тим вредностима сигнала долази до губитка рамова у слоју везе података. Пошто сваки изгубљени рам података носи у себи енкапсулиран IP пакет, а сваки пакет носи у себи TCP сегмент, тиме се проузрокују и губици у преносу TCP пакета. Након што мобилна станица изврши роминг и успостави стабилну конекцију са другим АР уређајем, поново се шаљу TCP пакети који су изгубљени у преносу непосредно пре роминга. Ова директна повезаност драстичног пада протока TCP пакета непосредно пре извршења роминга и ретрансмисије пакета одмах након завршетка роминга указује на то да праћење процента губитка рама података у слоју везе података може бити један од битних елемената алгоритма о доношењу одлуке о извршењу роминга. Посебан изазов у наредним истраживањима биће анализа саобраћаја у Wi-Fi мрежама са напредним управљањем роминг процесима где се разменом података и дирекном координацијом АР уређаја и клијента, АР уређаји неспоредно укључују у доношењу одлуке о оптималном тренутку извршења роминга.

ABSTRACT

The main goal of this paper is to present the basic principles of the experimental characterization of wireless computer networks, as well as the development of methods and procedures for measuring and analyzing measured results related to the monitoring of client roaming events and their impact on packet data transmission in the IEEE 802.11 network environment. Accordingly, starting from some existing solutions for measuring the handoff interval, combining, upgrading and adapting to the real conditions in the network, the process of measuring and analyzing results related to identification, basic roaming event characterization and monitoring of its impact on the network performance was developed and applied in the real environment of the IEEE 802.11 network, which might be considered as the main contribution of this experiment.

Roaming in 802.11 networks and its experimental characterization

Analiza uticaja arhitekture mreže na kvalitet signala u okviru LTE tehnologije

Ivana Stojanović, Mladen Koprivica, *Senior Member, IEEE*, Nenad Stojanović, Aleksandar Nešković, *Senior Member, IEEE*

***Apstrakt*—U radu je analiziran uticaj arhitekture mreže na kvalitet signala u okviru četvrte generacije javne mobilne mreže. Analiza je izvršena pomoću parametara RSRP *(Reference Signal Received Power)*, RSRQ (*Reference Signal Received Quality*) i realno ostvarivog protoka podataka. Parametri kvaliteta signala su prikupljeni merenjem pomoću TEMS *Investigation* i TEMS *Pocket* softvera. Merenja su sprovedena na Elektrotehničkom fakultetu u prizemlju zgrade Tehničkih fakulteta za scenario makro i mikro ćelije. Ustanovljeno je da se bolji kvalitet signala obezbeđuje u mikro ćelijama. Kvalitet signala je razmatran i po različitim servisima koji se obezbeđuju korisniku.**

***Ključne reči*—LTE, makro ćelija, mikro ćelija, kvalitet servisa.**

I. Uvod

Mobilne komunikacije su postale deo svakodnevnice. U poslednje dve decenije su evoluirale od skupe tehnologije koju su sebi mogli da priušte samo pojedinci, do danas kada su postale sveprisutni sistemi koje koristi većina svetske populacije. Tehnologija LTE (*Long Term Evolution*), predstavlja evoluciju postojećih sistema i nudi nekoliko prednosti za korisnike i operatere, u poređenju sa tehnologijama prethodnih generacija. Ova tehnologija dovela je do poboljšanja performansi i kapaciteta sistema, bolje iskorišćenosti radio resursa i smanjenja potrošnje energije.

Operateri planiraju radio mrežu raspoređivanjem baznih stanica. Nakon toga se najčešće vrši optimizacija mreže, za šta je neophodno izvršiti testiranje karakteristika na aktivnoj mobilnoj mreži. Iz tog razloga proizvođači telekomunikacione merne opreme imaju zadatak da nađu najjednostavniji način za merenje parametara potrebnih za analizu.

U ovom radu je izvršena eksperimentalna analiza performansi LTE tehnologije na aktivnoj mobilnoj mreži u prizemlju zgrade Elektrotehničkog fakulteta. Testirani su sledeći servisi: *web browsing* statičke stanice, *ping* veličine paketa 32 B, *video streaming*, *ping* veličine paketa 800 B, *file download* i *file upload*. Ovi servisi predstavljaju tipične servise LTE tehnologije. Takođe, posmatrani servisi su najčešće korišćeni servisi od strane studenata koji provode vreme u zgradi Elektrotehničkog fakulteta. Parametri koji su razmatrani su: *Reference Signal Received Power* (RSRP), *Reference Signal Received Quality* (RSRQ) i realno ostvariv protok prenosa podataka (*Throughput*). Prilikom merenja razmatrana su dva scenarija, kada se analizirani servis izvršavao preko makro i mikro ćelije. Makro scenario predstavlja slučaj kada mobilni terminal opslužuje makro ćelija bazne stanice, a mikro scenario kada to čini mikro ćelija bazne stanice. Izvršena je uporedna analiza rezultata dobijenih prilikom makro i mikro scenarija.

Slična istraživanja vršena su i u okviru UMTS (*Universal Mobile Telecommunication Systems*) tehnologije (treća generacija javne mobilne mreže). U [1] je pokazano da je uvođenjem mikro ćelija na odgovarajućim rastojanjima od makro ćelija, moguće poboljšanje funkcionisanja mreže. Poboljšanje mreže je prikazano kroz ostvaren protok prenosa podataka, odnos signal-šum (*Signal to Noise Ratio*, SNR) i nivo prijemnog signala kao parametara kvaliteta signala u UMTS mreži.

Ostatak rada organizovan je na sledeći način. U drugom poglavlju se govori o LTE tehnologiji, njenom nastanku i karakteristikama. Treće poglavlje sadrži opis korišćenog mernog postupka. U četvrtom poglavlju predstavljeni su rezultati prikupljenih podataka i uporedna analiza dobijenih rezultata. Konačno, u petom poglavlju dati su zaključci sa pravcima daljeg istraživanja.

II. Osnove LTE tehnologije i njenih parametara

A. Osnove LTE tehnologije

LTE je označena kao radio tehnologija četvrte generacije. Pojava LTE tehnologije je dovela do nekoliko tehnoloških rešenja koja su do tada bila nepoznata. Ciljevi prelaska na LTE mrežnu tehnologiju su: obezbeđenje većeg protoka podataka korisnicima, poboljšanje spektralne efikasnosti, realizacija znatno efikasnije paketske komutacije, poboljšanje i povećanje broja servisa i njihova implementacija, prevođenje mobilne mreže na isključivo paketsku mrežu i bolja integracija sa postojećim standardima prenosa i obrade signala [2].

Na *downlink* strani komunikacije LTE koristi OFDMA (*Orthogonal Frequency Division Multiple Access*) sistem višestrukog pristupa, što za rezultat ima robusniji sistem sa povećanim kapacitetom. Povećanje kapaciteta telekomunikacionog kanala se postiže multipleksiranjem

Ivana Stojanović – Telekom Srbija a.d., Bulevar umetnosti 16a, 11000 Beograd, Srbija i Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar kralja Aleksandra 73, 11120 Beograd, Srbija (e-mail: ivnvukanic@gmail.com).

Mladen Koprivica – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar kralja Aleksandra 73, 11120 Beograd, Srbija (e-mail: kopra@etf.rs).

Nenad Stojanović – Vojna akademija, Univerzitet odbrane u Beogradu, Generala Pavla Jurišića Šturma 33, 11000 Beograd, Srbija (e-mail: nivzvk@hotmail.com).

Aleksandar Nešković – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar kralja Aleksandra 73, 11120 Beograd, Srbija (e-mail: neshko@etf.rs).

korisničkih podataka malog protoka na širem kanalu, dok se robusnost postiže raspoređivanjem korisničkog saobraćaja po učestanostima kako bi se izbegla uskopojasna interferencija i feding usled višestruke propagacije. *Uplink* strana komunikacije koristi SC-FDMA (*Single Carrier-Frequency Division Multiple Access*) sistem višestrukog pristupa, čiji je najznačajniji faktor energetska efikasnost, kako bi se povećala pokrivenost i smanjili troškovi terminala i potrošnja energije. SC-FDMA ima nizak odnos vršne i srednje snage signala (*Peak to Average Power Ratio*, PAPR) što predstavlja glavni razlog korišćenja ove tehnike na *uplink* strani komunikacije [3].

Ovakav pristup kada se koriste dva različita sistema na *downlink* i *uplink* strani obezbeđuje ortogonalnost između korisnika, smanjenje interferencije i poboljšanje kapaciteta mreže [3]. Propusni opseg se može izabrati u intervalu od 1.4 MHz do 20 MHz u zavisnosti od raspoloživog spektra. Propusni opseg od 20 MHz obezbeđuje do 150 Mbps protoka na *downlink* strani komunikacije kada je u upotrebi 2x2 MIMO (*Multiple Input Multiple Output*) i 300 Mbps kada je u upotrebi 4x4 MIMO sistem. Protok na *uplink* strani može dostići i do 75 Mbps.

B. Opis korišćenih parametara LTE tehnologije

Radi procene kvaliteta performansi jednog digitalnog telekomunikacionog sistema najčešće se koristi verovatnoća bitske greške (*Bit Error Rate*, BER). U konkretnim telekomunikacionim sistemima koriste se i neki drugi načini procene kvaliteta signala kako bi se korisnicima obezbedila što bolja usluga. RSRP i RSRQ su pokazatelji kvaliteta signala koji se često koriste u optimizacji javne mobilne mreže LTE tehnologije.

RSRP predstavlja nivo snage signala na prijemu, ali ne govori o njegovom kvalitetu, već predstavlja indikator pokrivenosti ćelije [4]. Vrednost RSRP se izražava u dBm i služi kao metrika za odluku o reselekciji i *handover*–u.

RSRQ predstavlja parametar koji ukazuje na kvalitet primljenog signala [4]. Najpre se izmeri ukupni signal (i interferencija i šum) koji se prima u jednom OFDM (*Orthogonal Frequency Division Multiplex*) simbolu, čime se dobija vrednost RSSI (*Received Strength Signal Indicator*). Uporedo se meri i ukupna vrednost snage signala RSRP. Odnos ova dva parametra pomnožen sa brojem resurnih blokova daje konačnu vrednost RSRQ što se može predstaviti izrazom:

$$RSRQ = \frac{RSRP}{RSSI} N_{RB}, \qquad (1)$$

gde N_{RB} predstavlja broj resursnih blokova koji zavisi od propusnog opsega koji se koristi u LTE tehnologiji.

Ukoliko se korisnik nalazi u ruralnom području, posmatra se samo nivo RSRP zbog malog broja baznih stanica koje pokrivaju tu oblast. Međutim, ukoliko se korisnik nalazi u urbanom području sa zadovoljavajućim nivoom RSRP, ali se javlja velika interferencija zbog postojanja više baznih stanica u toj oblasti, na osnovu nivoa RSRQ se donosi zaključak kada je potrebno da mobilni terminal opslužuje druga bazna stanica (*handover*), a kada mobilni terminal može ostati na onoj koja ga trenutno opslužuje [5].

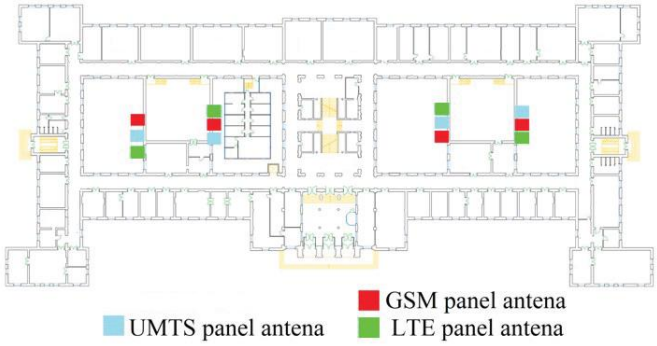
Binarni protok (*Throughput*), predstavlja brzinu prenosa bita u jedinici vremena u digitalnom telekomunikacionom sistemu. Realno ostvariv protok na liniji veze direktno utiče na performanse javne mobilne mreže, a posebno na kvalitet servisa baziranih na komutaciji paketa [6].

III. OPIS MERNOG POSTUPKA

Za potrebe merenja korišćen je TEMS *Investigation* softver i mobilni uređaj *Sony Xperia Z3 D6603* koji služi za prikupljanje podataka. TEMS *Investigation* je softverski alat za optimizaciju, verifikaciju, rešavanje problema i održavanje javne mobilne mreže. On prikuplja i obrađuje podatke, a zatim daje analizu u realnom vremenu. Tehnnologije koje podržava su: LTE (FDD (*Frequency Division Duplex*), TDD (*Time Division Duplex*)), WCDMA (*Wideband Code Division Multiple Access*) / HSPA (*High Speed Packet Access*) / HSPA+, GSM (*Global System for Mobile Communication*) / GPRS (*General Packet Radio Servis*), Wi-Fi (*Wireless-Fidelity*)…

Postupak merenja je obavljen na Elektrotehničkom fakultetu u prizemlju zgrade Tehničkih fakulteta Univerziteta u Beogradu za scenario makro i mikro ćelija. Merenja su vršena tokom radnog dana zbog najveće opterećenosti mreže u tom periodu. Za testiranje servisa LTE tehnologije korišćena je mobilna mreža Telekoma Srbije. Merenja su vršena u *indoor* okruženju, sprovedena je analiza za slučaj kada mobilni terminal opslužuje makro ćelija bazne stanice i za slučaj kada to čini mikro ćelija bazne stanice.

Tokom merenja član mernog tima se kretao prizemljem noseći sa sobom prenosivi računar i mobilni terminal na kojima su instalirani TEMS *Investigation* i TEMS *Pocket*, respektivno. Na računaru je u okviru korišćenog softvera pokretan skript koji se sastojao od niza servisa od interesa. Član mernog tima je jednom prošao kroz prizemlje i tom prilikom je celokupan skript ponovljen tri puta.



Sl. 1. Mapa prizemlja Elektrotehničkog fakulteta sa rasporedom antena baznih stanica GSM, UMTS i LTE tehnologija.

Položaj baznih stanica i izgled prizemlja u kome je vršeno merenje prikazan je na Sl. 1. Crvenom bojom su predstavljene pozicije GSM (*Global System for Mobile Communication*)

panel antena, plavom bojom UMTS (*Universal Mobile Telecommunication System*) pozicije panel antena i zelenom bojom su predstavljene pozicije LTE panel antena.

Merna procedura sastojala se u testiranju različitih servisa za scenario makro i mikro ćelije. Prikupljeni podaci su unošeni u *Matlab* i *Microsoft Office Excel* softverske alate pomoću kojih je potom vršena obrada merenih rezultata.

IV. REZULTATI

Na osnovu sprovedenih merenja grafički su prikazani dobijeni rezultati računanjem kumulativne funkcije raspodele verovatnoće (*Cumulative Distribution Function*, CDF) [7].

U Tabeli I [3] su prikazane referentne vrednosti opsega nivoa RSRP i RSRQ parametara LTE tehnologije, na osnovu kojih se utvrđuje stepen kvaliteta signala, odnosno kvalitet pružene usluge korisniku.

Na Sl. 2 predstavljen je nivo RSRP za makro i mikro scenario. Vrednosti nivoa RSRP se kreću u opsegu od -120 dBm do -95 dBm za scenario makro ćelije, tako da signal ulazi u tri opsega prikazana u Tabeli I. Oko 25% izmerenih vrednosti signala je nezadovoljavajućeg kvaliteta, 5% je signal dobrog kvaliteta, dok preostalih 70% čini signal zadovoljavajućeg kvaliteta. Vrednosti nivoa RSRP za scenario mikro ćelije se kreću u opsegu od -90 dBm do -55 dBm, što predstavlja odličan nivo signala na osnovu pokazatelja iz Tabele I. Dolazi se do zaključka da je značajno bolji nivo signala u slučaju mikro ćelije, što je i očekivano, jer se mikro bazna stanica nalazi na zidu zgrade Elektrotehničkog fakulteta, pa pruža bolju pokrivenost signalom.

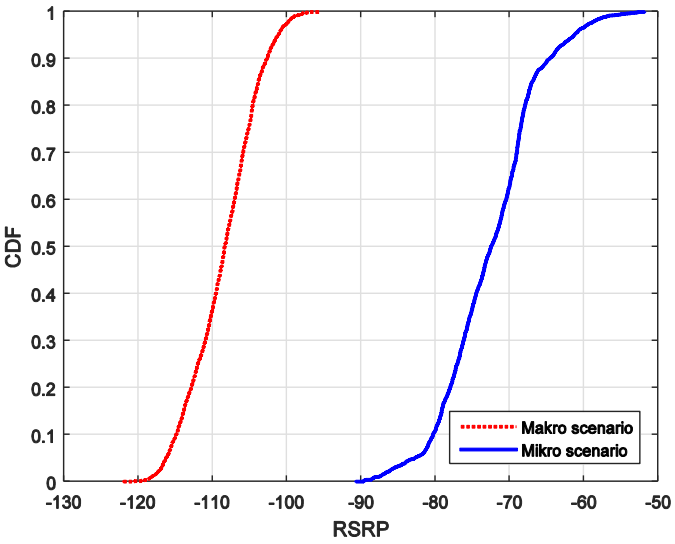
Tabela I
Vrednosti nivoa signala u odnosu na kvalitet

	Parametri	RSRP (dBm)	RSRQ (dB)
Kvalitet signala	Odličan	> -84	> -5
	Dobar	-102 do -85	-11 do -6
	Zadovoljavajući	-111 do -103	
	Nezadovoljavajući	< -112	< -12

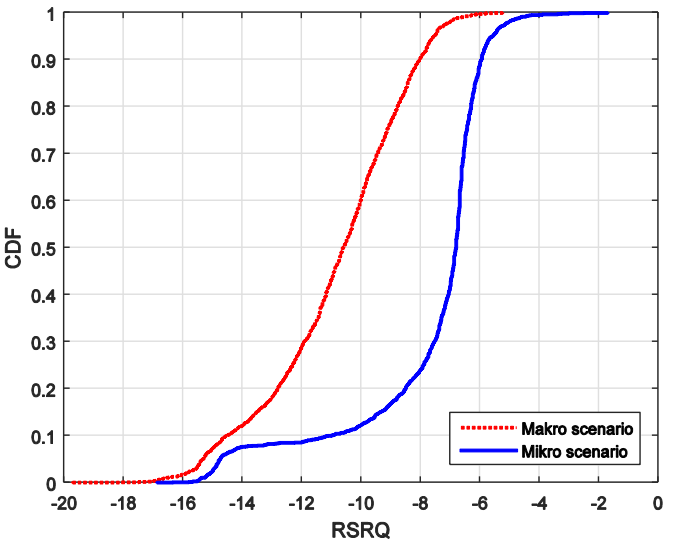
Za nivo RSRQ se može reći da je dobar ako se nalazi u opsegu od -11 dB do -6 dB. Za scenario makro ćelije nivo RSRQ se kreće u opsegu od -20 dB do -5 dB, dok se za mikro scenario nivo RSRQ kreće u opsegu od -16 dB do -2 dB, što je ilustrovano na Sl. 3. Vidi se da je nivo RSRQ bolji u mikro scenariju što je i očekivano zbog blizine mikro bazne stanice korisniku, ali i da u oba scenarija signal obuhvata sva tri nivoa kvaliteta signala predstavljena u Tabeli I.

Poređenje protoka za dva scenarija, kada se analizirano merenje izvršavalo preko makro i mikro ćelije, izvršeno je pomoću Sl. 4 i Sl. 5, gde su prikazani protoci u *downlink* i *uplink* smeru komunikacije. Na Sl. 4 predstavljene su normalizovane vrednosti protoka na *downlink* smeru komunikacije, za servis *download* u trajanju od 10 s. Vrednosti su normalizovane tako što je svaka od njih podeljena sa najvećom izmerenom vrednošću za servis *download* u trajanju od 10 s u okviru mikro ćelije. Viši protoci se ostvaruju u slučaju mikro scenarija i to više od dvostruke vrednosti brzine prenosa podataka u odnosu na makro scenario.

U slučaju brzine prenosa podataka na *uplink* smeru komunikacije za servis *upload* podataka u trajanju od 10 s takođe se viši protoci podataka dostižu u okviru mikro scenarija. Razlika u brzini prenosa podataka između makro i mikro scenarija je nešto manja nego u slučaju *downlink* smera komunikacije. I u ovom slučaju su vrednosti protoka podataka normalizovani maksimalnom vrednošću protoka kod servisa *upload* u intervalu od 10 s, na *uplink* smeru komunikacije. Navedeni protoci podataka na *upload* smeru komunikacije prikazani su na Sl. 5.



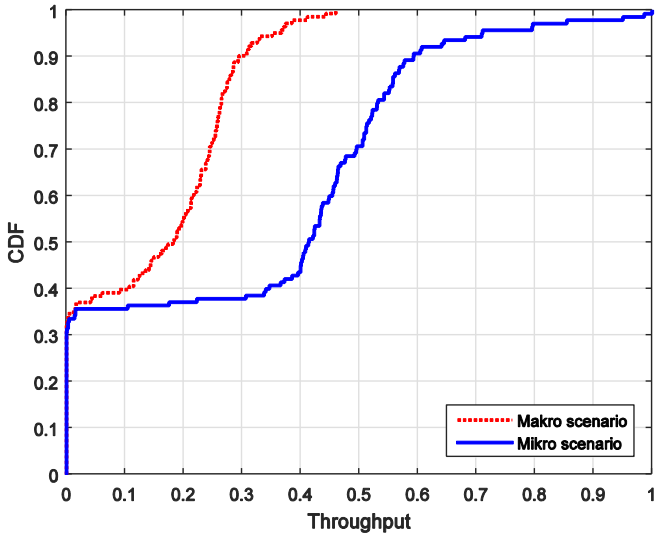
Sl. 2. Poređenje vrednosti RSRP za scenario makro i mikro ćelije.



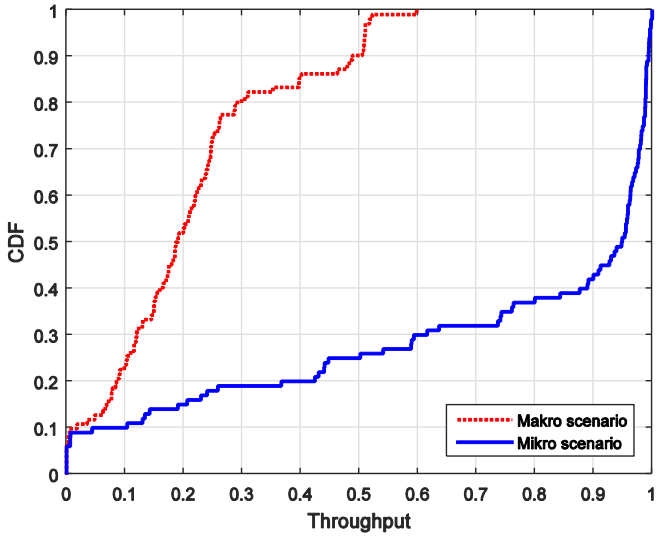
Sl. 3. Poređenje vrednosti RSRQ za scenario makro i mikro ćelije.

Na Sl. 6 i Sl. 7 prikazan je kvalitet signala u vidu RSRP i RSRQ u odnosu na najčešće servise koji se obezbeđuju

korisnicima. Prikazane vrednosti dobijene su tako što je najpre vršeno usrednjavanje nivoa signala nakon svakog od tri ponavljanja skripta tokom merenja, a zatim su usrednjene i tri novodobijene vrednosti. Za prikaz i analizu izabrani su *download* u trajanju od 10 s, *upload* u trajanju od 10 s, *download* 3 MB, *upload* 1 MB, učitavanje *web* stranice *youtube* i pregled videa sa *web* stranice *youtube*. Navedeni servisi su izabrani, jer se najčešće koriste od svih servisa koji su mereni tokom istraživanja. S obzirom na visoke protoke prenosa podataka koje nam omogućava LTE tehnologija, vreme potrebno za *download* 3 MB podataka je značajno kraće u odnosu na samo testiranje servisa *download* u trajanju od 10 s. Isto važi i za *upload* servis.



Sl. 4. Protok za servis *download* u trajanju od 10 sekundi na *downlink* smeru komunikacije za scenario makro i mikro ćelije.

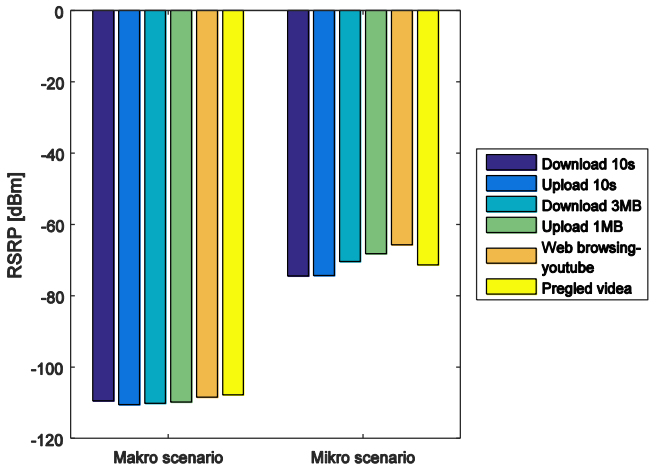


Sl. 5. Protok za servis *upload* u trajanju od 10 sekundi na *uplink* strani komunikacije za scenario makro i mikro ćelije.

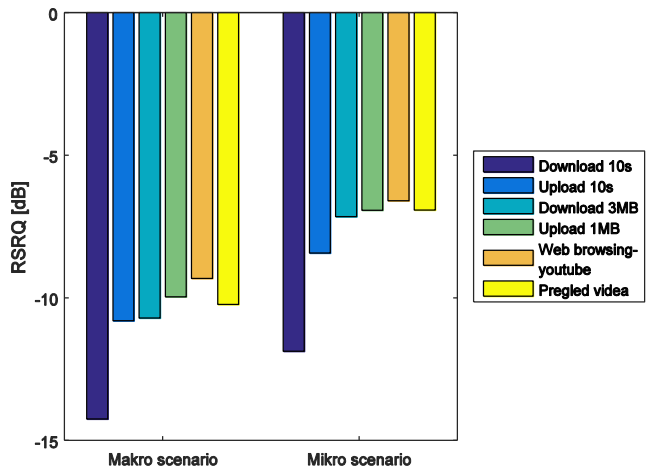
Vrednosti RSRP za makro scenario pokazuju da je za sve servise kvalitet signala na granici zadovoljavajućeg što značajno utiče na obavljanje komunikacije. Takođe, parametar RSRQ kod makro scenarija, za većinu testiranih servisa ima vrednosti oko granice između zadovoljavajućeg i nezadovoljavajućeg. Lošiji kvalitet signala javlja se prilikom *download* smera komunikacije u intervalu od 10 s, dok je prilikom učitavanja stranice *youtube* signal bio nešto boljeg kvaliteta u odnosu na signale kod ostalih servisa.

Kod mikro scenarija su dobijeni drugačiji rezultati. Posmatranjem parametra RSRP uočen je veoma visok stepen kvaliteta signala za sve testirane servise. Sve vrednosti RSRP su pokazale da se ostvaruje odličan nivo signala kada bazna stanica mikro ćelije opslužuje mobilni terminal na bliskom rastojanju. Parametar RSRQ i u ovom slučaju daje nešto drugačije rezultate. Servis *download* podataka u trajanju od 10 s i u ovom slučaju ima nezadovoljavajući nivo signala, dok se svi ostali servisi mogu svrstati u kategoriju signala sa dobrim kvalitetom kada se vrednosti dobijene merenjem uporede sa vrednostima iz Tabele I.

Sve prikazane vrednosti za parametre RSRP i RSRQ dobijene su usrednjavanjem svih izmerenih vrednosti, prilikom čega nije bilo značajnijih varijacija od srednje vrednosti merenih veličina.



Sl. 6. Vrednosti RSRP za scenario makro i mikro ćelije za različite servise.



Sl. 7. Vrednosti RSRQ za scenario makro i mikro ćelije za različite servise.

V. ZAKLJUČAK

U ovom radu je prikazan uticaj arhitekture mreže na kvalitet signala LTE sistema prenosa. Kroz izmerene vrednosti RSRP i RSRQ pokazano je da se bolji kvalitet dobija za mikro scenario. Kada se posmatra ostvareni protok podataka, pokazano je da se i prilikom *download* i *upload* komunikacije postižu viši protoci u okviru mikro scenarija, gde su postignute dvostruko veće brzine prenosa podataka nego u slučaju makro scenarija. Što se tiče posmatranih servisa najlošiji kvalitet signala se javlja kod *download* smera komunikacije u trajanju od 10 s, dok je najbolji kvalitet uočen prilikom učitavanja *web* stranice *youtube*.

U daljem radu moguće je posmatrati druge servise kao i druge lokacije na kojima bi se vršilo merenje. Takođe, merenje se može obavljati više dana kako bi se uočile neke pravilnosti u skladu sa brojem korisnika koji se nalaze na posmatranoj lokaciji. Na teritoriji Republike Srbije se očekuje povećanje saobraćaja u okviru LTE tehnologije, jer je implementacija ove tehnologije i dalje u toku, pa se očekuje da se eventualno dobiju i drugačiji rezultati. Na kraju, treba napomenuti da su u toku pripreme za uvođenje VoLTE (*Voice over LTE*) tehnologije koja će obezbediti servis govora, pa bi se i taj servis, najmanje otporan na bilo kakve smetnje u bežičnom telekomunikacionom kanalu, nekom narednom analizom trebao razmatrati.

ABSTRACT

In this paper the impact of the network arhitecture on signal quality in the fourth generation of the public mobile network is analyzed. The analysis was performed using RSRP (Reference Signal Received Power), RSRQ (Reference Signal Received Quality) and throughput parameters. The signal quality parameters were collected by measurement using TEMS Investigation and TEMS Pocket software. The measurements were carried out at the School of Electrical Engineering on the ground floor of the Technical Faculty building for the macro and micro cell scenario. It has been found that better signal quality is ensured in micro cells. The quality of the signal is also considered by the various services provided to the user.

Analysis of the impact of network architecture on signal quality in LTE technology

Uporedna analiza klasa *range-free* postupaka za lokalizaciju u bežičnim senzorskim mrežama

Kristina Josifović, Marko Matić, Gorana Crnobrnja, Dragana Lemaić, Goran Marković, *Member IEEE*

***Apstrakt* — Lokalizacija u bežičnim senzorskim mrežama (WSN, *Wireless Sensor Network*) predstavlja proces određivanja prostornih koordinata senzorskih čvorova (SN, *Sensor Nodes*), kao stvarnih, relativnih ili apsolutnih, pozicija u prostoru. Potreba za lokalizacijom SN u WSN javlja se u cilju proširenja funkcionalnosti na različite aspekte otkrivanja, praćenja, predikcije ili sprečavanja pojave određenih događaja u različitim primenama WSN. Predložene su mnoge tehnike za sprovođenje postupaka za lokalizaciju i definisane mere kvaliteta lokalizacije u vidu tačnosti i preciznosti lokalizacije. U radu je predstavljena numerička analiza performansi referentnih predstavnika klasa postupaka za *range-free* lokalizaciju, koja je izvršena krišćenjem razvijenog simulacionog modela u MatLab okruženju, za potrebe određivanja greške lokalizacije posmatranog skupa postupaka za različite scenarije primene. Na osnovu dobijenih rezultata, izvedeni su osnovni zaključci o mogućnosti primene posmatranog skupa *range-free* postupaka za lokalizaciju u WSN.**

***Ključne reči* — Bežične senzorske mreže, lokalizacija čvorova, centralizovani i distribuirani postupci, *range-free* lokalizacija.**

I. Uvod

LOKALIZACIJA predstavlja specifičan proces u okviru bežičnih senzorskih mreža (WSN, *Wireless Sensor Networks*) čija je svrha određivanje pozicije (lokacije) senzorskih nodova (SN, *Sensor Nodes*) u prostoru. Poznavanje pozicije SN u prostoru neophodno je u cilju ostvarivanja osnovne senzorske funkcije SN u WSN, i to onda kada je od interesa informacija o lokaciji na kojoj je izvršeno merenje posmatranog fizičkog fenomena. Dodatno, lokacija SN je bitna i za potrebe rutiranja senzorskih podataka kroz mrežu, njihove agregacije, kao i za izvođenje ostalih mrežnih protokola. Dodatno, poznavanje lokacije SN značajno je i za potrebe obavljanja detekcije, praćenja, lokalizacije, kontrole i prevencije pojave događaja (*event*) ili objekata u određenim primenama WSN. Proces lokalizacije podrazumeva estimaciju vrednosti prostornih koordinata svakog SN u mreži, ali se kao rezultat lokalizacije može definisati i prostorna oblast, kao deo fizičkog prostora, okarakterisana skupom koordinatnih tačaka. Ukoliko SN sam sprovodi proces svoje lokalizacije, često se koristi naziv samo-lokalizacija (eng. *self-localization*). Kao osnovne mere kvaliteta sprovedenog postupka za lokalizaciju SN najčešće se posmatraju procenat lokalizovanih SN, tačnost i preciznost lokalizacije. Kvalitet lokalizacije zavisi od različitih uticaja okruženja, topologije mreže, gustine prostornog rasporeda SN, kao i od degradirajućih efekata koji utiču na propagaciju signala koje mogu uneti greške pri merenjima parametara na osnovu kojih se obavlja postupak za lokalizaciju [1, 2]. Stoga, od interesa je da se različiti postupci za lokalizaciju analiziraju pri različitim scenarijima primene i uticaja okruženja, što je i bio jedan od osnovnih motiva istraživanja čiji su rezultati prikazani u okviru ovog rada.

Do sada je predložen veliki broj postupaka putem kojih se na različite načine određuju prostorne pozicije (lokacije) SN u WSN. Proces lokalizacije SN može se izvesti putem primene centralizovanog postupka, kada se na jednom mestu, najčešće pristupnom uređaju WSN, tj. *sink*-u, prikupljaju sve potrebne informacije (parametri) od svih SN, i na osnovu njih obavlja lokalizacija svih SN u mreži. Osim toga, postupak za lokalizaciju može biti distribuiran, kada svaki SN prikuplja potrebne informacije i sam određuje svoju lokaciju, a zatim o tome obaveštava ostatak mreže. U ovom slučaju, proces za lokalizaciju se često može podeliti u dve faze: prvu, u kojoj svaki SN određuje rastojanje ili konektivnost do svojih suseda i/ili referentnih čvorova (za koje je lokacija unapred poznata sa zadatom tačnošću), i drugu, kada svaki SN koristi te informacije kao i istovetne informacije dobijene od svojih suseda kako bi izvršio estimaciju svoje lokacije.

U postupku lokalizacije SN u okviru WSN, veoma često se koristi određeni broj referetnih čvorova (čije su koordinate *a priori* poznate), a koji znatno olakšavaju i povećavaju kvalitet procesa lokalizacije. Ovi referentni čvorovi imaju iste funkcije kao i ostali SN u mreži, ali mogu imati složeniji hardver, npr. opremljeni su GPS (*Global Positioning System*) prijemnicima za potrebe pozicioniranja, ili se planski postavljaju na tačno određenim, unapred poznatim, pozicijama u prostoru. Ovakvi čvorovi nazivaju se *beacon* čvorovi (BN, *Beacon Nodes*), pri čemu je dokazano da njihovo prisustvo u WSN omogućava velika poboljšanja kvaliteta lokalizacije ostalih SN, kao i da je neretko njihovo prisustvo u WSN čak i neophodno kako bi se lokalizacija SN u mreži uspešno obavila, [1-5].

U ovom radu, najpre je data osnovna klasifikacija i pregled postupaka za lokalizaciju, sa posebnim osvrtom na veoma jednostavnu grupu postupaka, tzv. *range-free* postupaka, koja za svoj rad ne zahteva poseban hardver kao ni određivanje međusobnih rastojanja SN u mreži. Nakon toga, prikazani su

rezultati uporedne analize tipičnih predstavnika klasa *range-free* postupaka za lokalizaciju SN za određen skup scenarija primene, uz navođenje osnovnih izvedenih zaključaka analize.

II. KLASIFIKACIJA I PREGLED POSTUPAKA ZA LOKALIZACIJU

Osnovna podela postupaka za lokalizaciju može se izvršiti na *range-based* i *range-free* postupke, [1-3]. U prvu grupu, *range-based*, spadaju oni postupci za lokalizaciju zasnovani na određivanju međusobnog rastojanja SN, u kojima se potom putem primene trilateracije, triangulacije ili multilateracije određuje lokacija za sve SN u mreži. Druga grupa, *range-free* postupaka za lokalizaciju, [3], zasniva se najčešće na primeni informacija o međusobnoj konektivnosti SN, tj. povezanosti SN u okviru mreže, a lokacija SN određuje se bez direktnog merenja rastojanja između SN ili posrednog određivanja na osnovu nivoa snage signala na prijemu (RSSI, *Received Signal Strength Idicative*). Kod *range-free* postupaka za lokalizaciju, BN imaju izuzetno bitnu ulogu, kao referentne tačke za potrebe procene pozicije SN.

Merenje međusobnog rastojanja između SN može se vršiti na osnovu više različitih parametara [1, 2]. Najjednostavniji postupak je merenje vremena propagacije signala (ToA , *Time of Arrival*), sa pretpostavkom da je rastojanje između SN proporcionalno vremenu za koje radio signal stigne od jednog SN do drugog. Sa druge strane, može se meriti razlika vremena propagacije signala između dva čvora (TDoA, *Time Difference of Arrival*), gde se posmatraju trenuci prispeća dva signala koja se prenose različitim brzinama, pri čemu se ne zahteva sinhronizacija početnog i krajnjeg čvora. Dodatno, primena RSSI zasnovanih postupaka podrazumeva merenje nivoa snage signala na predaji i prijemu kod SN, kao i poznavanje modela slabljenja radio signala usled propagacije, pri čemu se ne zahteva dodatni hardver jer SN poseduju radio prijemnike. Konačno, merenje upadnog ugla pri prijemu radio signala (AoA, *Angle of Arrival*), gde se posmatra ugao prispeća signala u SN u odnosu na referentni pravac, može koristiti kao parametar za lokalizaciju SN. Određivanjem prethodno navedenih parametara, uz poznavanje koordinata BN, u okviru *range-based* postupaka lokalizacije obavljaju se proračuni lokacije SN uz primenu tehnika triangulacije, trilateracije ili multilateracije, [2].

U okviru *range-free* postupaka lokalizacije takođe se koriste BN, a mogu se koristiti i RSSI vrednosti koje se, za razliku od *range-based* pristupa, koriste samo za indikaciju relativnog odnosa, ali ne i samu estimaciju rastojanja između čvorova. Rad *range-free* postupaka za lokalizaciju znatno se više oslanja na međusobnu komunikaciju SN i BN, i razmenu potrebnih informacija, čime SN jedni drugima pomažu u postupku lokalizacije. Važno je napomenuti da se *range-free* postupci za lokalizaciju mogu realizovati i kao centralizovani, i kao distribuirani postupci. Pri tome, kod centralizovanih postupaka podrazumeva se da u mreži postoji centralni uređaj, najčešće *sink*, kojem se šalju podaci svih SN, a koji te podatke obrađuje, i obavlja procenu lokacije za svaki SN. Prednost centralizovanog pristupa je to da *sink* dobija potpun skup informacija potrebnih za lokalizaciju, te ima znatno više podataka za potrebe donošenja preciznih odluka o lokaciji svih SN u datoj mreži. Nedostaci centralizovanog postupka lokalizacije su jako složena implementacija, visoki zahtevi u smislu procesorske snage uređaja koji obavlja lokalizaciju (usled obrade velike količine podataka i složenog postupka optimizacije), i veoma velika potrošnja energije za potrebe dostavljanja potrebnih informacija od svih SN u mreži. Sa druge strane, distribuirani postupci za lokalizaciju rade na principu samo-lokalizacije, u kome svaki SN sam određuje svoju lokaciju na osnovu razmene podataka sa susednim SN i BN. Distribuirani postupci za lokalizaciju su jednostavniji za implementaciju, za njihov rad se zahteva znatno manji nivo komunikacije u mreži, a posledično se troši i značajno manja količina energije. Ipak, ove pogodnosti se postižu po cenu slabije tačnosti i preciznosti lokalizacije, [1, 2].

U radu su, kao posebno interesantni, analizirani *range-free* postupci za lokalizaciju. Pri tome, najpre su opisani neki tipični predstavnici centralizovanih i distribuiranih postupaka za lokalizaciju, a potom su ovi postupci razmatrani u okviru procesa analize čiji su rezultati prikazani u ovom radu.

Approximate Point in Triangulation (APIT) postupak za lokalizaciju, [4, 5], je tipičan predstavnik distribuiranih postupaka, i on zahteva primenu manjeg broja BN u mreži. BN periodično šalju *beacon* signale ka susednim SN u mreži, pa su u cilju ostvarivanja većeg dometa radio-komunikacije, opremljeni predajnicima veće snage. Kako bi se obavila lokalizacija posmatranog SN, on mora biti u dometu barem tri BN koji emituju *beacon* signale ka svim susednim čvorovima u mreži. Svaki SN, ili drugi BN, prima *beacon* signale koji nose informaciju o koordinatama predajnika (BN), zapisuje tu informaciju, kao i vrednost RSSI parametra signala, i razmenjuje ih lokalnom komunikacijom sa susednim SN. Formiraju se sve moguće kombinacije trouglova, čija temena čine po tri BN, od svih dostupnih BN u mreži. Za svaki posmatrani SN, izdvajaju se trouglovi u kojima se on nalazi, tako što se upoređuju nivoi snage primljenih *beacon* signala za taj SN i za sve njegove susede koji su primili signale istog skupa BN, a težište preseka svih takvih trouglova predstavlja koordinate datog SN. Opisani postupak se obavlja posebno za svaki SN u mreži i naziva se APIT test, [4, 5].

Drugi predstavnik distribuiranih postupaka lokalizacije je *Distance Vector – Hop* (DV-Hop) postupak, [6], koji se realizuje u tri faze, i koji funkcioniše na osnovu korišćenja multilateracije. U prvoj fazi se obavlja plavljenje mreže tzv. *beacon* paketima, pri čemu se kao parametri koriste broj *hop*-ova (koraka) pri prosleđivanju paketa kroz mrežu i koordinate BN koji su izvor paketa. Brojač koraka je inicijalno postavljen na nulu i inkrementira se svaki put kad dođe do drugog čvora, pri čemu se svaki novi paket prosleđuje sa inkrementiranim brojem koraka. Druga faza postupka, podrazumeva da BN određuju prosečnu dužinu *hop*-a do svakog drugog BN proračunom srednje vrednosti rastojanja, d_i, [6],

$$d_i = \frac{\sum_{i \neq j}^{N} \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2}}{\sum_{i \neq j}^{N} h_{ij}}, \quad (1)$$

gde je h_{ij} broj koraka između i-tog i j-tog BN od N BN, a (x_i, y_i) i (x_j, y_j) su koordinate i-tog i j-tog BN, respektivno. U trećoj fazi, svaki SN sam određuje svoju lokaciju korišćenjem metode najmanjih kvadrata (LS, *Least Square*). Pri tome, SN pamti minimalnu vrednost koraka do BN, tj. bira se optimalna putanja do onog BN za dati SN sa najmanjim brojem posredničkih čvorova. Procenjuje se prosečna dužina koraka kroz optimalne putanje, uz proračun korekcionog faktora koji se propagira kroz mrežu i koristi kao dodatni parametar za proračun lokacije SN, [6].

Centroid Localization Algorithm (CLA), [7], je distribuiran postupak za lokalizaciju koji se zasniva na poznavanju konektivnosti posmatranog SN i skupa dostupnih BN. Pri tome, koristi se *broadcast* princip slanja *beacon* signala od BN koji sadrže koordinate BN, a procena pozicije SN obavlja se prostim usrednjavanjem koordinata skupa BN u čijem se dometu nalazi posmatrani k-ti SN, odnosno imamo da je lokacija određena sa, [7],

$$(x_k, y_k) = \left(\frac{\sum_{j=1}^{N_k} x_j}{N_k}, \frac{\sum_{j=1}^{N_k} y_j}{N_k}\right), \quad (2)$$

gde su (x_k, y_k) koordinate posmatranog SN, a (x_j, y_j) koordinate BN, dok je N_k broj BN sa kojima je dati SN konektivan. CLA predstavlja jedan od najjednostavnijih *range-free* postupaka za lokalizaciju, pri čemu je *Weighted* CLA (W-CLA) [8, 9] verovatno najznačajnija varijanta ovog postupka. Naime, CLA postupak ne uzima u obzir uticaj udaljenosti pojedinačnih dostupnih BN od posmatranog SN, dok W-CLA postupak koristi i informacije o težinskim koeficijentima koji označavaju procenat učešća koordinata svakog od BN pri lokalizaciji SN. Kao težinski koeficijent najčešće se koriste RSSI parametri, a koji direktno zavise od rastojanja, na osnovu sledećih izraza, [8, 9],

$$w_{jk} = \left(d_{jk}\right)^{-g} = \left(P_{ref} \times 10^{(RSSI_{jk}/20)}\right)^{g}, \quad (3)$$

$$(x_k, y_k) = \left(\frac{\sum_{j=1}^{N_k} w_{jk} \times x_j}{\sum_{j=1}^{N_k} w_{jk}}, \frac{\sum_{j=1}^{N_i} w_{jk} \times y_j}{\sum_{j=1}^{N_k} w_{jk}}\right) \quad (4)$$

gde je w_{jk} težinski koeficijent k-tog SN i j-tog BN, d_{jk} je njihovo međusobno rastojanje, P_{ref} referentna snaga BN, g je usvojena vrednost propagacionog slabljenja, dok je $RSSI_{jk}$ nivo snage signala j-tog BN na prijemu u k-tom SN, pri čemu je N_k broj BN sa kojima je dati SN konektivan.

Još jedna predložena izmena CLA postupka za lokalizaciju je *Compensated* CLA (C-CLA), [9], zasnovana na poznavanju konektivnosti posmatranog SN i skupa BN u dometu, kao u osnovnom CLA postupku i W-CLA modifikaciji. Kod C-CLA postupka uvodi se određena razlika u načinu procene težinskih koeficijenata, odnosno posmatra se broj dostupnih BN za posmatrani SN kao dodatni parametar, i uvodi se pravilo da težinski koeficijenti dostupnih BN imaju veću vrednost ukoliko njih ima više, a na osnovu toga što se očekuje da je u tom slučaju rastojanje između njih i posmatranog SN manje. U okviru C-CLA postupka koristi se izraz (3) za procenu ovih koeficijenata isto kao i W-CLA, dok se izraz, [9],

$$w'_{jk} = w_{jk} \times {N_k}^{2 \times w_{jk}}, \quad (5)$$

koristi za procenu novog težinskog koeficijenta w'_{kj} na osnovu vrednosti osnovnog koeficijenta w_{jk} iz izraza (4), pri čemu je N_k ukupan broj dostupnih BN za posmatrani SN.

Mnoge implementacije WSN ne zahtevaju veliku tačnost i preciznost, već samo grubu procenu pozicije svih SN. Jedno rešenje, koje koristi centralizovani pristup za lokalizaciju je *Convex Position Estimation* (CPE) postupak, [10]. CPE postupak se zasniva na primeni *beacon* signala koje šalju BN i SN, putem kojih SN dobijaju informacije o konektivnosti svih čvorova u mreži. Svaku WSN posmatramo kao graf sa n čvorova. Prvih m čvorova su BN čije su koordinate poznate, a preostalih $n - m$ su SN koje treba lokalizovati. Pri tome, proces optimizacije koji se koristi u okviru CPE postupka zahteva određivanje takvih vrednosti skupa koordinata $(x_i, y_i), i = 1, \cdots, n$, da rastojanje čvorova koji su konektivni bude manje ili jednako maksimalnom dometu svakog SN pri komunikaicji između SN, ili dometu BN pri komunikaciji BN i SN. Svaki SN mora da popuni tabelu povezanosti sa drugim SN/BN u mreži, tj. upisuje podatke o rastojanju između njega i ostalih čvorova sa kojima komunicira. Svaki čvor zatim šalje ovakvu tabelu ka *sink*-u koji procesira prikupljene informacije na osnovu kojih donosi odluku o lokacijama SN. CPE postupak koristi *semidefinite* programiranje za određivanje optimalnog rešenja, a u ovom radu korišćen je dostupni alat mosek za optimizaciju, [11].

Recursive Position Estimation (RPE), [12, 13], predstavlja rekurzivan postupak za estimaciju lokacije SN, koji se može primeniti na lokalizaciju SN u WSN velikih dimenzija. RPE postupak se zasniva na korišćenju informacije o međusobnoj konektivnosti SN, ali se za razliku od CPE koriste samo lokalne informacije (distribuiran postupak). Prva faza RPE postupka podrazumeva određivanje skupa lokalno dostupnih BN, dok se u drugoj fazi se primenom postupka sličnim sa CPE postupkom, ali ovog puta u samom SN sprovodi samo-lokalizacija datog SN. U četvrtoj, završnoj fazi, SN koji su imali dovoljno lokalnih informacija za samo-lokalizaciju, pridružuju se skupu referentnih čvorova, pa se oblast u kojoj je moguća lokalizacija iterativno povećava. RPE postupak omogućava visoku fleksibilnost pri realizaciji lokalizacije u WSN, ali po cenu manje tačnosti pošto greška određivanja lokacije SN iz prethodnih iteracija RPE postupka, koji ulaze u skup referentnih za naredne iteracije, negativno utiče na kvalitet lokalizacije SN u narednim iteracijama, [12, 13].

III. SIMULACIONI MODEL I REZULTATI SPROVEDENE ANALIZE

Za potrebe uporedne analize prethodno navedenih tipičnih predstavnika pojedinih klasa *range-free* postupaka razvijen je poseban simulacioni model u MatLAB okruženju. Posmatrana je WSN dimenzija senzorskog polja 250 m×250 m, koju čine 5×5 kvadratne ćelije, sa $N_{BC} \in \{1,2,4\}$ pravilno raspoređenih BN i 8 SN slučajnog rasporeda po ćeliji (ukupno 200 u WSN).

Posmatrani su scenariji rada WSN u kojima je domet BN u komunikaciji sa SN bio vrednosti $R_{BC} \in \{35\,m, 50\,m, 100\,m\}$, dok je domet između SN $R_{SN} \in \{25\,m, 35\,m, 50\,m\}$. Posmatran je idealan slučaj propagacije, u kojoj su svi SN u dometu BN/SN međusobno konektivni, kao i to da su potrebni podaci o konektivnosti čvorova u mreži i vrednosti RSSI (koja se koristi kod nekih postupaka, npr. APIT, W-CLA, C-CLA) bile dostupne u svim SN, pri čemu je za W-CLA i C-CLA postupke predpostavljena vrednost parametra $g = 1.5$.

Generisan je skup od 100 nezavisnih postavki WSN za svaki scenario (*Monte-Carlo* eksperimenata), uz primenu skupa postupaka za lokalizaciju (APIT, CLA, C-CLA, W-CLA, CPE, RPE i DV-Hop) realizovanih u skladu sa opisom iz literature. Poređenjem sa tačnim vrednostima, određena je srednja vrednost i varijansa greške lokalizacije za svaki scenario i postupak, pri čemu su rezultati u pogledu srednje greške lokalizacije prikazani u **TABELA 1**, odnosno varijanse greške u **TABELA 2** (prikazana je najveća vrednost varijanse zabeležena na skupu svih eksperimenata - postavki WSN). Pri tome, u cilju preglednosti nisu dati rezultati za CLA i C-CLA postupke, kojima su dobijani nešto lošiji rezultati u odnosu na W-CLA postupak, uz vrlo slično ponašanje sa promenom parametara scenarija. Dodatno nisu dati rezultati za domet BN od 100 m za koji je za sve postupke i domete SN ostvaren lošiji kvalitet lokalizacije u odnosu na manje domete.

TABELA 1 - SREDNJA GREŠKA LOKALIZACIJE [M] U ZAVISNOSTI OD BROJA BN PO ĆELIJI (1, 2 ILI 4), DOMETA BN (35, 50) I DOMETA SN (25, 35, 50)

N_{BC} = 1	**APIT**	**W-CLA**	**CPE**	**RPE**	**DV-Hop**

R_{BC}=50,R_{SN}=25	21.7050	3.9173	9.0742	11.0431	27.4979
R_{BC}=50,R_{SN}=35	17.9319	3.9461	9.7577	11.8677	26.1945
R_{BC}=50,R_{SN}=50	17.1553	3.9343	11.3036	14.0260	24.5250

Analizom dobijenih rezultata, može se uočiti da za većinu postupaka srednja greška lokalizacije opada sa povećanjem broja BN u mreži (tj. porasta gustine prostornog rasporeda BN u mreži), osim za APIT za manje domete BN i DV-Hop za veće vrednosti dometa SN i/ili izuzetno veliki broj BN kada se smanji prosečan broj *hop*-ova između BN, odnosno kada je veći broj BN direktno konektivan. Može se zaključiti da APIT postupak lokalizacije karakterišu znatno lošije performanse u odnosu na sve ostale razmatrane postupke. Za distribuirane RPE i DV-Hop postupke, porast dometa SN kao i povećanje broja BN, generalno dovodi do opadanja vrednosti srednje greške lokalizacije (osim za suviše veliki broj BN u mreži kod DV-Hop postupka), dok povećanje dometa BN, kada ih ima manji broj u okviru WSN, pozitivno utiče na tačnost lokalizacije. Kod DV-Hop postupka se može zapaziti i to da se najbolji rezultati ostvaruju za slične iste vrednosti dometa SN i BN (tj. za iste vrednosti za manje domete BN odnosno nešto manje vrednosti dometa SN za veće domete BN). Ovo je posledica principa rada DV-Hop protokola, kod koga se procenjuje srednja dužina *hop*-a u mreži pa suviše različiti dometi SN i BN mogu usloviti porast greške procene (ne vodi se računa o tome da li se radi o vezi SN sa SN ili SN sa BN). Sa druge strane, u slučaju centralizovanog CPE postupka, kao i distribuirane postupke CLA, W-CLA i C-CLA, povećanje broja BN uvek uslovljava opadanje srednje vrednosti greške lokalizacije. Kod ovih postupaka, povećanjem dometa BN osim za izuzetno veliku gustinu prostornog rasporeda BN (tj. $N_{BC} = 4$), ostvaruju se veća tačnost i preciznost lokalizacije. Pri tome, smanjivanje dometa SN za datu grupu postupaka doprinosi povećanju tačnosti i preciznosti lokalizacije. Ovu grupu postupaka, kao što vidi u **TABELA 2** karakteriše i znatno veća preciznost lokalizacije (manja varijansa greške) u odnosu na ostale postupke na čiji rad u ovom pogledu značajno utiče raspored SN u okviru senzorskog polja date WSN, odnosno u odnosu na skup BN koji se koristi za lokalizaciju datog SN.

TABELA 2 - VARIJANSA LOKALIZACIJE [M] U ZAVISNOSTI OD BROJA BN PO ĆELIJI (1, 2 ILI 4), DOMETA BN (35, 50) I DOMETA SN (25, 35, 50)

R_{BC}=50,R_{SN}=50	85.97	21.41	100.03	680.73	336.59

Sprovedena je i analiza u cilju određivanja osetljivosti datih postupaka na grešku poznavanja lokacije BN sa varijansom greške reda 0.25 m, čiji su rezultati dati u **TABELA 3**. Uočava se da *range-free* postupci imaju veoma malu osetljivost (u smislu povećanja srednje greške lokalizacije) na grešku poznavanja lokacija BN (radi preglednosti nisu dati rezultati

za 4 BN po ćeliji – dobijaju se slične vrednosti kao u **TABELA 1** za iste parametre scenarija), dok se kod CPE postupka javlja velika osetljivost kada imamo veći broj BN u mreži uz manje vrednosti dometa BN i veće vrednosti dometa SN.

TABELA 2 - SREDNJA GREŠKA LOKALIZACIJE [m] U ZAVISNOSTI OD BROJA BN PO ĆELIJI (1, 2 ILI 4), DOMETA BN (35, 50) I DOMETA SN (25, 35, 50), U SLUČAJU POSTOJANJA GREŠKE POZNAVANJA LOKACIJE BN

IV. ZAKLJUČAK

Na osnovu rezultata sprovedene analize, zaključuje se da se dobar kvalitet lokalizacije SN, za određene uslove (parametre scenarija primene WSN) može ostvariti kako korišćenjem distribuiranih (npr. W-CLA), tako i centralizovanih postupaka (npr. CPE) za lokalizaciju. Pri tome, pri projektovanju WSN treba odrediti pogodan izvor u smislu dometa BN i broja BN (tj. gustine rasporeda), kao i dometa SN u skladu sa izabranim postupkom za lokalizaciju (ili obrnuto), kako bi se postigla prihvatljiva greška lokalizacije SN sa što manjim brojem BN.

Centralizovani postupci za lokalizaciju zahtevaju znatno veću potrošnju energije, pa imajući u vidu da se sličan kvalitet lokalizacije može ostvariti i distribuiranim postupcima, za WSN većih dimenzija treba razmotriti primenu distribuiranih postupaka. Naime, u WSN ovog tipa javljaju se znatno veća rastojanja između SN, kao i veća prosečna rastojanja SN do pristupnog uređaja (*sink*) u kome se prikupljaju informacije. Posledično, primenu centralizovanih postupaka zato odlikuju znatno veći zahtevi po pitanju količine bežične komunikacije i potrošnje energije neophodne za potrebe lokalizacije.

Može se očekivati da se daljom analizom može odrediti povoljna kombinacija postupaka za lokalizaciju čijom bi se sekvencijalnom primenom u više koraka, ili u sklopu nekog iterativnog kooperativnog postupka u kome SN sarađuju u cilju poboljšanja kvaliteta lokalizacije, obezbedilo optimalno ponašanje u smislu uspešnosti lokalizacije, potrošnje energije pri komunikaciji za potebe lokalizacije i optimizaciju (uz minimizaciju) broja i dometa BN koji bi se koristio u tako dobijenom postupku lokalizacije.

ZAHVALNICA

Rad je delimično finansiran od Ministarstva prosvete, nauke i tehnološkog razvoja RS, kroz projekte tehnološkog razvoja 32028 i 32037.

ABSTRACT

Localization in Wireless Sensor Networks (WSN) is the process of determining the spatial coordinates of Sensor Nodes (SN), in order to determine their actual position, relative or absolute. The requisite for SN localization arises to extend the WSN functionality to the aspects of detection, tracking, prediction and prevention of the occurrence of certain events in various WSN applications. Many localization techniques have been proposed and the measures of quality of localization in the form of accuracy and precision have been defined. In this paper, we present the numerical analysis of referent *range-free* localization procedures performance, executed by using simulation model developed in the MatLAB program package, which we used to calculate the localization error in different application scenarios for here considered localization procedures. Based on the obtained results, we drawn the conclusions on the application of these localization procedures in the WSN.

Comparative analysis of several classes of range-free localization algorithms in wireless sensor network

Unapređenje postupaka za lokalizaciju u WSN sa kombinovanjem DV-Hop i Centroid rešenja

Gorana Crnobrnja, Kristina Josifović i Goran Marković, *Member, IEEE*

***Apstrakt* — Lokalizacija, kao postupak određivanja pozicije senzorskih čvorova u okviru bežičnih senzorskih mreža (WSN, *Wireless Sensor Network*), karakteriše se tačnošću i preciznošću estimacije prostornih koordinata (lokacija) na kojima se čvorovi nalaze. Predložen je veliki broj rešenja za potrebe lokalizacije u WSN, na osnovu različitih pristupa, u cilju poboljšanja kvaliteta lokalizacije. Jedno od predloženih rešenja je *Distance Vector – Hop* (DV-Hop) postupak lokalizacije. U ovom radu posmatran je originalan DV-Hop postupak, kao i modifikacije ovog postupka zasnovane na kombinovanju DV-Hop postupka i jednostavnog *Centroid* postupka. Predložena je dodatna modifikacija postupka ovog tipa u cilju daljeg unapređenja performansi ove klase postupaka za lokalizaciju, odnosno izvršena je uporedna analiza performansi DV-Hop zasnovanih postupaka, *Centroid* postupka, i skupa modifikovanih postupaka zasnovanih na kombinovanju ova dva osnovna postupka za lokalizaciju. Za potrebe analize performansi postupaka lokalizacije za različite scenarije primene u WSN samostalno je razvijen specifičan simulacioni model, čijom primenom su dobijeni rezultati na osnovu kojih je izvršena analiza mogućnosti primene skupa postupaka namenjenih za lokalizaciju u okviru WSN u slučaju mreža većih dimenzija.**

***Ključne reči* — Bežične senzorske mreže, postupci za lokalizaciju, DV-Hop lokalizacija, *Centroid* postupak.**

I. Uvod

BRZI razvoj bežičnih komunikacionih tehnologija, kao i razvoj tehnologija za izradu senzora doveli su do pojave bežičnih senzorskih mreža (WSN, *Wireless Sensor Networks*). U okviru ovih mreža koriste se uređaji malih dimenzija i ograničenih mogućnosti (ograničeno napajanje električnom energijom, mala procesorska snaga i raspoloživa memorija,..), senzorski nodovi (SN, *Sensor Nodes*), koji omogućavaju prikupljanje informacija o okruženju (primenom senzora) i njihovo dostavljanje (primenom bežične komunikacije) kroz mrežu. WSN imaju brojne i značajne primene u životnom i radnom okruženju, industriji, ekologiji i mnogim drugim sferama, [1, 2]. Pri tome, ove mreže predstavljaju pogodno rešenje za primene u kojima postoji potreba za prikupljanjem podataka iz fizičkog okruženja za potrebe kontrole, nadzora i upravljanja sredinom. Za praktičnu primenu WSN često je neophodno da se, uz prikupljene senzorske podatke, da i tačna lokacija na kojima je obavljeno merenje, ali zbog zahteva za malom cenom, potrošnjom energije i veličinom, SN najčešće nisu opremljeni GPS (*Global Positioning System*) modulima za potrebe određivanja pozicije u prostoru (lokacije SN).

Pod lokalizacijom SN podrazumeva se proces određivanja njihove nepoznate pozicije u prostoru (lokacije). Za potrebe lokalizacije SN u WSN do sada je predložena primena velikog broja različitih postupaka posebno razvijenih za ove potrebe, [1, 2]. Za potrebe lokalizacije u WSN, ali i drugim bežičnim mrežama, često se koriste referentni (*beacon*) čvorovi (BN, *Beacon Node*) za koje je poznata tačna lokacija, a koji kroz komunikaciju sa ostalim SN omogućavaju lokalizaciju ovih SN sa većom tačnošću i preciznošću. Pri tome, tačna lokacija referentnih čvorova određuje se primenom ugrađenih GPS modula ili postavljanjem na unapred definisane pozicije.

Postupci za lokalizaciju SN u WSN mogu se klasifikovati na više načina. Jedan način klasifikacije je na distribuirane i centralizovane postupke. Distribuirani postupci su oni kod kojih se procena lokacije odvija zasebno u svakom SN mreže, tj. svaki SN određuje svoju lokaciju na osnovu podataka koje dobija od susenih čvorova ili referentnihh čvorova. Nasuprot tome, kod centralizovanih postupaka definiše se glavni čvor, najčešće *sink,* koji sakuplja sve informacije na nivou mreže i obavlja procenu lokacija svih SN. Generalno, centralizovani postupci omogućavaju bolje rezultate u pogledu tačnosti i preciznosti lokalizacije na račun povećane potrošnje energije i složenosti postupka, [1]. Distribuirani postupci predstavljaju znatno jednostavnija rešenja sa stanovišta implementacije, a koje odlikuju znatno manji zahtevi u smislu razmene podataka (komunikacije) i potrošnje energije, ali po cenu nešto lošijih performansi lokalizacije, [1, 2]. Sa druge strane, klasifikacija postupaka za lokalizaciju može se izvršiti na *range-based* i *range-free* postupke za lokalizaciju. U *range-based* postupke ubrajamo one u kojima se primenom dodatnih hardverskih komponenti i/ili posebnih postupaka merenja, pod određenim pretpostavkama, određuje međusobno rastojanje SN, a nakon toga, primenom trilateracije ili multilateracije, i pozicija SN. Postupci za lokalizaciju u kojima se ne koriste dodatne hardverske komponente, niti se obavlja merenje međusobnih rastojanja SN za potrebe lokalizacije nazivamo *range-free* postupcima. Kod *range-based* postupaka za lokalizaciju, [1], procena rastojanja između SN i BN, odnosno međusobnog rastojanja SN obavlja se na osnovu merenja vremena prispeća signala (TOA, *Time of Arrival*), razlike vremena prispeća signala između SN (DTOA, *Difference Time of Arrival*), merenja ugla nailaska signala (AOA, *Angle of Arrival*) ili merenja snage signala na prijemu (RSSI, *Received Signal Strength Indicator*). U slučaju *range-free* postupaka, [1, 2] ne

koriste se navedeni parametri, već se kao osnovna informacija koriste podaci o konektivnosti SN sa drugim čvorovima mreže, pri čemu se svi podaci upisuju u tabelu rutiranja u svakom SN. Ovakvi postupci ne zahtevaju primenu dodatnog hardvera, što ih čini pogodnijim za implementaciju u WSN. Iako ova grupa postupaka za lokalizaciju ne obezbeđuje podjednako dobar kvalitet lokalizacije SN kao *range-based* postupci, oni zbog jednostavnosti i cene implementacije ipak predstavljaju dobar izbor u slučaju mreža u kojima se zahteva samo gruba procena pozicije SN. U najpoznatije *range-free* postupke mogu se svrstati sledeći postupci za lokalizaciju: *Centroid Localization Algorithm* (CLA), *Convex Position Estimation* (CPE), *Approximate Point in Triangulation* (APIT)*, Distance Vector – Hop* (DV-Hop), [1, 3-11].

Centroid Localization Algorithm (CLA), [3], predstavlja jedan od najjednostavnijih *range-free* postupaka. U CLA se koriste podaci o konektivnosti posmatranog SN i dostupnih BN. Prostorne koordinate SN određuju se kao centar oblasti formirane od BN, u čijem dometu se nalazi posmatrani SN, i to prostim usrednjavanjem prostornih koordinata ovih BN. Osim osnovnog CLA postupka predloženi su i unapređeni postupci zasnovani na CLA. *Weighted* CLA (WCLA) pripada ovom skupu unapređenih algoritama, ali kod njega se, za razliku od osnovnog CLA postupka, uvode dodatni težinski koeficijenti za određivanje procenta učešća dostupnih BN u proceni lokacije SN u zavisnosti od rastojanja BN i posmatranog SN, [12, 13]. Ipak, u WCLA postupku se obavlja merenje rastojanja BN i SN, odnosno procena rastojanja na osnovu vrednosti RSSI i predpostavljenog modela propagacije radio signala (tzv. *path-loss* model), te on spada u *range-based* postupke lokalizacije.

Osnovni DV-Hop (DVH) postupak, [6, 7], zasniva se na pristupu distribuirane lokalizacije SN. Osim osnovnog DVH postupka, predložene su različite modifikacije bazirane na ovom osnovnom DV-Hop postupku, a koje odlikuju neke prednosti u pogledu performansi lokalizacije, [7-9]. Osim toga, predložena je i posebna grupa postupaka za lokalizaciju koja je bazirana na kombinaciji jednostavnog CLA postupka i DVH postupka. Motiv za razvoj ove grupe postupaka je da se kombinovanjem prevaziđu nedostaci i istaknu prednosti DVH i CLA postupaka. Naime, CLA postupak ne uzima u obzir uticaj udaljenosti između BN i SN, odnosno činjenicu da što je BN bliži SN, to njegov uticaj na procenu lokacije SN treba da bude relativno veći, odnosno da takve BN treba smatrati prikladnijim za estimaciju lokalizacije datog SN, kao što je to slučaj u pomenutom WCLA postupku. Osim toga, za uspešnu primenu CLA postupka, kao i za prethodno navedene *range-based* postupke zasnovane na CLA postupku (npr. WCLA), [12, 13], neophodna je relativno velika gustina prostornog rasporeda BN kao i/ili njihov veliki domet, kako bi za svaki SN u mreži postojao dovoljno veliki skup BN u čijem se dometu dati SN nalazi, kako bi lokalizacija mogla da se izvrši. U slučaju WSN velikih dimenzija sa malom gustinom BN u senzorskom polju WSN, odnosno kada je domet BN relativno mali u odnosu na dimenzije mreže (što je slučaj posmatran u ovom radu) CLA i na njemu zasnovane postuke odlikuju relativno loše performanse lokalizacije pri čemu se javlja veliki procenat SN koje nije moguće lokalizovati.

Kako bi se pravazišao problem nedovolje konektivnosti SN sa dostupnim skupom BN, odnosno da bi se omogućilo da se pri primeni osnovnog principa lokalizacije na bazi CLA postupka u obzir uračuna uticaj rastojanja između BN i SN, predloženo je kombinovanje DVH i CLA postupaka. Tipični postupci ovog tipa su WCA (*Weighted Centroid Algorithm*) postupak, [10, 11], i *Improved* WCA (IWCA) postupak, [11]. U ovim modifikovanim postupcima procena rastojanja između BN i SN određuje se korišćenjem mehanizma DVH postupka, i proširuje mogući skup BN koji se mogu koristiti za potrebe lokalizacije na osnovu konektivnosti posmatranog SN kome se određuje lokacija i BN ostvarene *multi-hop* komunikacijom preko drugih SN u mreži.

Analizom prethodno navedenih WCA i IWCA postupaka za lokalizaciju uočeno je da oni ne obavljaju na najbolji mogući način procenu rastojanja SN i BN primenom DVH mehanizma, i stoga ne postižu očekivana poboljšanja kvaliteta lokalizacije. Daljom modifikacijom IWCA postupka, koja je predložena u ovom radu kao modifikovani IWCA (MIWCA) postupak, ostvarene su nešto bolje performanse lokalizacije SN u WSN većih dimenzija u scenarijima primene u kojima ne postoji dovoljna konektivnost SN sa BN neophodna za primenu CLA postupka. Komparativna analiza performansi svih ovde razmatranih *range-free* postupaka za lokalizaciju obavljena je korišćenjem numeričke analize izvedene putem specijalno razvijenog simulacionog modela WSN u okruženju programskog paketa MatLab, koja je izvršena za različite scenarije primene u pogledu broja BN (tj. gustine rasporeda BN u senzorskom polju), dometa BN i dometa SN. Rezultati sprovedene analize pokazali su da za analizirani slučaj niske konektivnosti postoje određene prednosti ovde predloženog MIWCA postupka u odnosu na druge posmatrane postupke.

U drugom poglavlju rada, dat je sažeti opis osnovnog (originalnog) DVH postupka i IDVH postupka za lokalizaciju, dok su u trećem opisani WCA, IWCA i MIWCA postupci na bazi kombinovanja CLA i DVH pristupa za potrebe *range-free* lokalizacije. Opis simulacionog modela, razvijenog i korišćenog za analizu performansi razmatranih postupaka za lokalizaciju za različite scenarije primene u WSN i osnovni rezultati analize, prikazani su u četvrtom poglavlju, dok su u poslednjem, petom poglavlju data zaključna razmatranja.

II. OSNOVNI I UNAPREĐENI DV-HOP POSTUPAK

A. Osnovni DV-Hop postupak

Osnovni DV-Hop postupak za lokalizaciju sadrži tri faze rada kroz koje vrši estimaciju lokacija svih SN u mreži. U prvoj fazi svaki BN obavlja plavljenje (*flooding*) mreže *beacon* paketima koji sadrže podatak o poznatim i tačnim lokacijama tog BN. Svaki čvor u mreži, BN ili SN, proverava koji od primljenih paketa od istog BN sadrži najmanji broj *hop*-ova, tj. koraka, od datog BN i taj paket zadržava, dok ostale odbacuje. Čvor inkrementira broj *hop*-ova iz izabranog paketa za 1 i prosleđuje paket dalje kroz mrežu. Cilj ove faze je da svaki čvor mreže formira tabelu rutiranja sa najmanjim brojem koraka (*hop*-ova) ka svim ostalim čvorovima mreže.

Sledeća, druga, faza služi za proračun prosečne dužine *hop*-a između BN u mreži, kao aritmetičke sredine svih *hop*-ova zabeleženih u tabeli rutiranja koji čine najkraću putanju između svaka dva BN. Svi BN šalju podatak o prosečnoj dužini *hop*-a ka svim SN u mreži, dok SN čuva i prosleđuje podatak o paketu koji je prvi primio, što osigurava da je sačuvao informaciju onog BN koji mu je najbliži. Nakon toga, svaki, k-ti SN određuje rastojanje od svih BN u mreži, d_{ik}, na osnovu relacije (2), koristeći kao parametre prosečnu dužinu *hop*-a za najbliži BN (koju je sačuvao), Hop_size_i, i broj hopova do ostalih BN u mreži, [6, 7],

$$Hop\_size_i = \frac{\sum_{j \neq i} \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2}}{\sum_{j \neq i} h_{ji}}, \quad (1)$$

$$d_{ik} = Hop\_size_i \times h_{ik}, \quad (2)$$

gde je h_{ik} broj hop-*ova* (koraka) između i-tog BN i k-tog SN, a (x_i, y_i) i (x_j, y_j) su koordinate i-tog i j-tog BN, respektivno.

U trećoj fazi koristi se *Least Square* (LS) metod za potrebe određivanja lokacije, koju svaki SN sprovodi za sebe, a na osnovu izabranog skupa BN, i procene rastojanja do tih BN.

Iako poseduje određene kvalitete, DV-Hop algoritam ima i bitne nedostatke, a koji se ogledaju u tome da stvarni razmak između čvorova mreže bitno odstupa od procenjenih vrednosti u izrazima (1) i (2). Naime, procene rastojanja SN i BN iz izraza (2), i međusobnih rastojanja BN na osnovu izraza (1), predstavljaju samo grube procene, odnosno greška u proceni rastojanja nastaje usled toga što se koristi srednja dužina *hop*-samo za najbliži BN datom SN, dok je realna dužina svakog *hop*-a u mreži različita i zavisi od lokacija BN i SN.

Kako bi se smanjio uticaj navedene greške, razvijeni su modifikovani DV-Hop postupci. Jedan takav postupak opisan je u nastavku ovog poglavlja, dok su oni koji predstavljaju kombinaciju DVH i CLA postupaka opisani u sledećem poglavlju, u kome je definisan i MIWCA postupak.

B. Improved DV-Hop (IDVH) postupak

Improved DV-Hop (IDVH) postupak, [8], razvijen je u cilju poboljšanja tačnosti određivanja lokacije u odnosu na osnovni DVH postupak uz minimalne izmene koje su jednostavne za implementaciju. U odnosu na osnovni DVH postupak, izmene se kod IDVH postupka uvode u drugoj i trećoj fazi. U drugoj fazi, SN, ne određuje samo srednju dužinu *hop*-a do najbližeg BN, već usrednjava srednje dužine *hop*-a za sve BN, odnosno određuje se prosečna dužina *hop*-a $Hop\_size_{average}$, na nivou cele WSN, kao, [8],

$$Hop\_size_{average} = \frac{\sum_{i=1}^{N} Hop\_size_i}{N}, \quad (3)$$

gde N predstavlja ukupan broj BN, a Hop_size_i prosečnu dužinu *hop*-a za svaki BN iz izraza (1). Dodatno, u izrazu (2) za proračun rastojanja do svih BN u mreži koristi se samo prosečna dužina *hop*-a dobijena korišćenjem izraza (3). Treća faza se razlikuje po tome što se ne koristi LS metod, već se za lokalizaciju primenjuje 2-D *Hyperbolic* algoritam, [9].

III. MODIFIKOVANI POSTUPCI ZASNOVANI NA KOMBINACIJI DVH I CLA POSTUPAKA I PREDLOG NOVOG MIWCA POSTUPKA

A. WCA i IWCA postupci bazirani na DV-Hop postupku

WCA postupak uveden je u cilju prevazilaženja nedostatka CLA postupka vezanog za to da se pri estimaciji lokacije SN koriste lokacije svih BN sa kojima je konektivan bez obzira na rastojanje BN i datog SN. U slučaju WCA postupka uvode se težinski koeficijenati, koji uzimaju u obzir udaljenost BN od SN. Odnosno, procena lokacije k-tog SN u slučaju WCA postupka data je na osnovu izraza, [10],

$$x_k = \frac{\sum_{i=1}^{N_k} w_{ik} \times x_i}{\sum_{i=1}^{N_k} w_{ik}}, \quad y_k = \frac{\sum_{i=1}^{N_k} w_{ik} \times y_i}{\sum_{i=1}^{N_k} w_{ik}}, \quad (4)$$

gde su (x_i, y_i) koordinate i-tog BN, w_{ik} težinski koeficijenti, dok je N_k je ukupan broj BN sa kojima je dati k-ti SN konektivan. Postupak se može primeniti kada u WSN postoji manji broj BN, jednostavan je za implementaciju i može se primeniti za svaki SN u mreži. Pri tome, težinski koeficijenti w_{ik} se određuju na osnovu primene prve faze DVH postupka, tj. nakon što svaki k-ti SN prikupi podatak o minimalnom broju *hop*-ova h_{ik} do i-tog BN, na osnovu izraza, [10, 11],

$$w_{ik} = \frac{1}{h_{ik}}, \quad (5)$$

Na osnovu opisa WCA postupka, očigledno je da što je veći broj *hop*-ova, to je BN udaljeniji od SN i tada je njegov relativan uticaj na procenu lokacije SN manji.

U slučaju kada je broj *hop*-ova između SN i BN u proseku znatno veći, a stvarno rastojanje između njih manje, dolazi do povećanja greške određivanja lokacije u slučaju primene WCA, [11]. Ovo se događa u slučaju kada u mreži postoji veći broj SN (tj. kada se poveća gustina prostornog rasporeda SN), ili kada se smanji broj BN u odnosu na broj SN u mreži. Stoga je predložen IWCA postupak koji treba da u navedenim uslovima da bolje rezultate lokalizacije u odnosu na WCA postupak. U slučaju IWCA postupka, u trenutku kada SN dobije podatak o minimalnom broju *hop*-ova do svakog BN, obavlja se sortiranje u rastućem poretku i bira se nekoliko BN sa najmanjim brojem koraka. Prosečna dužina *hop*-ova se računa na osnovu tih nekoliko izabranih BN, kao, [11],

$$Hop\_size_{k,IWCA} = \frac{\sum_{j=1}^{N_k} Hop\_size_j}{N_k}, \quad (6)$$

gde je N_k broj prethodno izabranih BN, a Hop_size_j je prosečna dužina *hop*-a za j-ti BN iz izraza (1). Težinski koeficijenti za k-ti SN i i-ti BN definisani su izrazom, [11],

$$w_{ik,IWCA} = \left(\frac{1}{h_{ik}}\right)^{1/n_k} \quad (7)$$

pri čemu je $n_k = Hop\_size_{k,IWCA}/r$, a r je domet SN. Sama estimacija prostornih koordinata SN obavlja se korišćenjem izraza (4) samo uz primenu $w_{ik,IWCA}$ umesto w_{ik}.

B. Predlog dodatne modifikacije IWCA postupka (MIWCA)

Ovde je predložena dodatna modifikacija IWCA postupka, označena kao MIWCA postupak, za potrebe lokalizacije SN u WSN velikih dimenzija. Na osnovu rezultata sprovedene numeričke analize za prethodno opisane DVH, IDVH, CLA, WCA i IWCA postupke, a koji su dati u narednom poglavlju, uočeno je da srednja greška lokalizacije pri primeni težinskih koeficijenata definisanih u WCA i IWCA postupcima ne opada na očekivani način u odnosu na CLA i DVH postupke. Dodatno, zapaženo je da jednostavan CLA postupak ostvaruje znatno bolje performanse u odnosu na DVH i IDVH postupke, u slučaju velike gustine i većeg dometa BN u mreži, dok se za mreže sa malim brojem (gustinom prostornog rasporeda) BN najbolji rezultati postižu primenom IDVH postupka, pri čemu CLA postupak za malu gustinu prostornog rasporeda i manje domete BN ne omogućava klasifikaciju značajnog procenta SN u mreži (SN nisu konektivni sa dovoljnim brojem BN). Pri tome, na osnovu detaljnije analize ponašanja CLA, DVH i IWCA postupaka uvedene su određene izmene.

U MIWCA postupku se na kraju prve faze DVH postupka, nakon što SN dobije informaciju o minimalnom broju *hop*-ova do svakog BN, obavlja sortiranje po rastućem broju *hop*-ova, i za dalji postupak lokalizacije odabira skup BN koj sadrži N_k članova. Pri tome, definisan je maksimalan broj BN u skupu, N_{max}, uz maksimalni broj od 3 *hop*-a do datog SN. Dodatno je postavljen uslov da se skup BN sa 2 ili 3 *hop*-a koristi samo ukoliko je njihov broj veći od broja BN na rastojanju od 1 *hop*-a (skup BN koji se koristi u okviru CLA postupka) pošto se zapaža da je ovaj uslov pretežno ispunjen samo ako je SN udaljen od ivice senzorskog polja (za SN bliske obodu senzorskog polja se pri korišćenju većeg broja udaljenih BN javlja porast greške lokalizacije – estimirana lokacija se pomera ka centru senzorskog polja). Nakon toga, umesto da se usrednjeva prosečne dužine hopova za N_k odabranih BN, izraz (6) iz IWCA postupka, usrednjava se broj *hop*-ova između N_i odabranih BN i posmatranog SN. U tom slučaju, težinski koeficijenti za k-ti SN i i-ti BN određuju kao,

$$n_{k,MIWCA} = Hop_{k,average} = \frac{\sum_{j=1}^{N_k} h_{kj}}{N_k}, \quad (8)$$

$$w_{ik,MIWCA} = \left(\frac{1}{h_{ik}}\right)^{1/n_{k,IMWCA}} \quad (9)$$

Nakon toga, proces estimacije lokacija SN sprovodi se na isti način kao i kod IWCA postupka.

IV. SIMULACIONI MODEL I REZULTATI NUMERIČKE ANALIZE

Za potrebe analize performansi navedenih postupaka za lokalizaciju razvijen je poseban simulacioni model u MatLab okruženju. Posmatrana je WSN dimenzija senzorskog polja 250 m×250 m, koju čine 5×5 kvadratne ćelije, sa $N_{BC} = 1, 2$ ili 4 pravilno raspoređenih BN i 8 SN slučajnog rasporeda po ćeliji (ukupno 200 u okviru WSN). Posmatrani su scenariji rada WSN u kojima je domet BN u komunikaciji sa SN bio vrednosti $R_{BC} \in \{35\text{ m}, 50\text{ m}, 100\text{ m}\}$, odnosno skup dometa komunikacije između SN $R_{SN} \in \{25\text{ m}, 35\text{ m}, 50\text{ m}\}$. Posmatran je model sa idealnom propagacijom, u kome su svi BN/SN na rastojanju manjem od dometa bežične komunikacije (dometa BN ili SN) konektivni, odnosno smatrano je da su svi potrebni podaci o konektivnosti čvorova dostupni svim SN.

Generisan je skup od 200 međusobno nezavisnih postavki WSN (*Monte-Carlo* eksperimenata) za svaki od scenarija, uz primenu skupa algoritama za lokalizaciju (DVH, IDVH, CLA, WCA, IWCA i MIWCA) realizovanih u potpunosti u skladu sa opisom u literaturi, odnosno opisom MIWCA datim u poglavlju III.B. Poređenjem estimiranih lokacija SN sa tačnim lokacijama, za sve analizirane postupke za lokalizaciju određena je srednja vrednost i varijansa greške lokalizacije za svaki scenario, pri čemu su rezultati u pogledu srednje greške lokalizacije prikazani u **TABELA 1**. U cilju preglednosti nisu dati rezultati za IWCA postupak, kojim su za sve scenarije dobijani nešto lošiji rezultati u odnosu na WCA postupak, uz slično ponašanje sa promenom parametara scenarija. Dodatno nisu dati rezultati za domet BN od 100 m za koji je za sve postupke za lokalizaciju i domete SN ostvaren lošiji kvalitet lokalizacije u odnosu na manje vrednosti dometa.

TABELA 1 - SREDNJA GREŠKA LOKALIZACIJE [m] U ZAVISNOSTI OD BROJA BN PO ĆELIJI (1, 2 ILI 4), DOMETA BN (35, 50) I DOMETA SN (25, 35, 50)

N_{BC} = 1	DVH	IDVH	CLA	WCA	MIWCA

Na osnovu dobijenih rezultata utvrđeno je da kod DVH, IDVH, IWCA postupaka vrednost srednje greške lokalizacije povećava ako se povećava broj BN u mreži, a što je posledica smanjenja prosečnog broja *hop*-ova između BN, odnosno između SN i skupa bliskih BN, što izaziva povećanje greške estimacije srednje dužine *hop*-a. Nasuprot tome, za CLA i MIWCA postupke srednja greška lokalizacije se smanjuje pri povećanju broja BN u WSN, zato što se javlja veći broj BN na malom rastojanju do svakog SN. Osim toga, u slučaju CLA postupka porast vrednosti dometa BN za isti broj BN u WSN omogućava poboljšanje kvaliteta lokalizacije samo kada

imamo manji broj BN u mreži (usled povećanja broja BN koji su konektivni sa SN), dok za veći broj BN (gustinu BN u mreži) srednja greška lokalizacije počinje da se povećava sa porastom dometa BN. U slučaju MIWCA postupka povećanje dometa BN i SN uglavnom izaziva pogoršanje uspešnosti lokalizacije (osim za slučaj srednje gustine i malog dometa BN - $N_{BC} = 2$ i $R_{BC} = 35m$ u **TABELA 1** kada se najbolji rezultati ostvaruju za srednji domet SN). Kada domet BN postane suviše veliki (100 m) broj *hop*-ova između BN drastično opada ili su oni direktno konektivni, dok broj BN koji je direktno konektivan sa posmatranim SN drastično raste, pa se ostvaruju izuzetno loši rezultati lokalizacije za sve razmatrane postupke. Analizaran je i uticaj dometa SN. Pokazuje se da povećanje dometa SN nema značajan uticaj na grešku lokalizacije kod CLA posupka, što je posledica toga što se u okviru ovog postupka ne ostvaruje komunikacija između SN, dok se kod DVH i IDVH postupaka uočava da su srednje vrednosti dometa (35 m) pogodne za mali broj BN u mreži ($N_{BC} = 1$) ili veće domete BN (npr. 50 m), dok se za manje vrednosti dometa BN (25 m) bolji rezultati ostvaruju kada imamo veći broj BN u mreži. Kao što je već navedeno, kod MIWCA postupka, povećanje dometa SN generalno izaziva pad kvaliteta lokalizacije, zbog pojave većih rastojanja do skupa BN koji se koriste za lokalizaciju datog SN.

Treba naglasiti da se u slučaju CLA postupka, ako se posmatra samo srednja greška lokalizacije ostvaruju veoma dobri rezultati, osim u slučaju kada je gustina rasporeda BN u mreži mala ($N_{BC} = 1$), a kada se za manje domete BN ($R_{BC} = 35m$) javlja slučaj da određen procenat SN ne može da bude lokalizovan (u **TABELA 1** je data srednja greška samo za one SN koji su uspešno lokalizovani). Dodatno, zapaža se da se za SN bliske središtu senzorskog polja ostvaruje mnogo bolji kvalitet lokalizacije, dok se za SN bliske ivicama senzorskog polja greška lokalizacije drastično povećava. Slično ponašanje se može zapaziti i u slučaju MIWCA postupka.

Procenjena vrednost srednje varijanse greške lokalizacije za posmatrani skup postupaka i parametre simulacionog modela prikazan je u **TABELA 2.** Uočava se da CLA i MIWCA postupci u pogledu uticaja parametara scenarija imaju slično ponašanje u pogledu varijanse greške, a koje je usklađeno sa onim koje se javlja za srednju grešku lokalizacije. Ostali posmatrani postupci imaju značajno veću (za neke scenarije i drastično veću) varijansu greške lokalizacije u odnosu na onu zabeleženu kod CLA i MIWCA postupaka.

Dodatno, sprovedena je i analiza performansi u pogledu osetljivosti na grešku poznavanja lokacije BN sa definisanom varijansom greške reda 0.25 m, čiji su rezultati dati u **TABELA 3**. Poređenjem rezultata u **TABELA 1** i **TABELA 3** za iste parametre scenarija (broj BN, domet BN i domet SN), ukazuje na to da posmatrani *range-free* algoritmi, imaju veoma malu osetljivost (u smislu povećanja greške) na grešku lokacija BN.

Ukupno gledano, za scenarije primene sa malim i srednjim brojem BN (mala i srednja gustina prostornog rasporeda BN), a pogotovu u slučaju manjih vrednosti dometa BN, MIWCA postupak za lokalizaciju predstavlja najbolje rešenje od ovde posmatranih postupaka, pri čemu se za veće domete BN ostvaruju slične ili malo lošije karakteristike u poređenju sa CLA postupkom. Sa druge strane, za veliku gustinu BN u mreži, CLA postupak predstavlja najbolje rešenje, sa nešto lošijim performansama u slučaju većih vrednosti dometa BN kada postaje poredIv po kvalitetu sa MIWCA postupkom, odnosno obezbeđuje najbolji kvalitet lokalizacije SN u odnosu na ostale ovde posmatrane *range-free* postupke.

TABELA 2 - VARIJANSA GREŠKE LOKALIZACIJE [m^2] U ZAVISNOSTI OD BROJA BN PO ĆELIJI (1, 2 ILI 4), DOMETA BN (35, 50) I DOMETA SN (25, 35, 50)

V. ZAKLJUČAK

Na osnovu rezultata izvršene numeričke analize zaključuje se da nije moguće dati istovetan opšti zaključak o uticaju parametara scenarija primene za sve analizirane postupke za lokalizaciju, prvenstveno zato što određene grupe postupaka rade na različitim principima. Iako je očekivano (na osnovu literature) da ranije predloženi modifikovani postupci (IDVH,

WCA, IWCA) ostvaruju bolje rezultate od originalnog DVH postupka, tokom same numeričke analize pokazalo se da za određene scenarije primene (prevashodno u funkciji gustine prostornog rasporeda BN i dometa BN) postoje značajna odstupanja. Delimično i usled specifičnog pravilnog rasporeda BN u modelu mreže korišćenog za potrebe analize, predloženi MIWCA postupak ostvaruje bolje rezultate u pogledu srednje greške lokalizacije u odnosu na sve posmatrane postupke, osim u odnosu na CLA postupak. Pri tome, MIWCA postupak ima nešto bolje performanse za mreže sa manjim brojem i dometom BN, dok se u slučaju velike gustine BN u mreži najbolje performanse ostvaruju primenom CLA postupka. Kod oba ova postupka za lokalizaciju javlja se znatno manja greška lokalizacije za SN bliže centru a znatno veća za SN bliže ivicama senzorskog polja. MIWCA/CLA postupci za lokalizaciju za posmatrane scenarije primene poseduju znatno bolje performanse u odnosu na WCA/IWCA postupke, i vidno nadmašuju DVH i IDVH postupke.

Treba imati u vidu, da je CLA postupak najjednostavniji od ovde razmatranih postupaka, kao i to da ne zahteva dodatnu komunikaciju između SN, a samim tim ni potrošnju energije za potrebe razmene podataka koji se koriste za lokalizaciju. U tom smislu, on predstavlja izuzetno pogodno rešenje za WSN u kojima čvorovi imaju ograničenu raspoloživu energiju, ali se pri tome mora voditi računa da je njegova uspešna primena moguća samo ukoliko postoji veći broj gusto raspoređenih BN sa relativno velikim dometom. Svi navedeni postupci spadaju u klasu *range-free* postupaka i stoga za svoj rad ne zahtevaju dodatni hardver, što je takođe pogodno za primenu u WSN.

Pokazano je da je moguće izvršiti dodatne modifikacije ranije predloženih rešenja na bazi kombinovanja jednostavnog CLA postupka i originalnog DVH postupka, kojim se može generisati rešenje za potrebe lokalizacije pogodno za scenarije primene u kojima nije moguće na zadovoljavajući način primeniti originalne postupke. Ipak, treba naglasiti da je ovde prikazano rešenje (MIWCA postupak), iako omogućava uspešnu lokalizaciju u određenim uslovima primene u WSN, sa nešto boljim kvalitetom lokalizacije od drugih razmatranih protokola, prvenstveno razvijeno kako bi se ispitalo da li je moguće uspešno kombinovati pristupe na bazi CLA i DVH postupaka tako da se dobije rešenje pogodno za primenu u različitim uslovima rada. Konačno, može se zaključiti da je nophodno dalje istraživanje u cilju razvoja jednostavnog rešenja za lokalizaciju u WSN, kojim bi se između ostalog rešio problem lokalizacije SN bliskih ivicama senzorskog polja a koji postoji kod svih postupaka zasnovanih na primeni CLA i DVH koncepata lokalizacije.

ZAHVALNICA

Rad je delimično finansiran od Ministarstva prosvete, nauke i tehnološkog razvoja RS, kroz projekte tehnološkog razvoja 32028 i 32037.

ABSTRACT

Localization, as a process that determine the positions of sensor nodes (SN) within wireless sensor networks (WSN), is characterized by the SN coordinates (locations) estimation accuracy and precision. Various solutions for SN localization have been proposed, with the aim of improving quality measures in different ways. One of them is Distance Vector-Hop (DV-Hop) localization procedure. In this paper we give an overview of the original DV-Hop procedure, some modifications based on combining original DV-Hop procedure and a simple Centroid localization. We also propose a modified solution that should introduce further performance improvement. The detailed performance analysis for the observed localization procedures was performed. A specific simulation model is developed, in order to perform the performance analysis for the different WSN application scenarios. Based on the numerical analysis results the applicability of here considered *range-free* localization procedures in large-scale wireless sensor networks was examined.

The Improvement of Localization Procedures for WSN based on Combining of DV-Hop and Centroid Algorithms

Srednja verovatnoća greške po bitu pri prenosu modulisanog signala u FSO sistemu

Jelena Todorović, Branimir Jakšić, Petar Spalević, Mile Petrović i Ana Tošković

***Apstrakt*—U radu je izračunata i analizirana srednja verovatnoća greške po bitu (Average Bit Error Rate) signala u Free Space Optical sistemu modulisanim sa Differential Phase Shift Keying i Binary Phase Shift Keying šemom. Srednja verovatnoća greške po bitu je određena za slučaj atmosferskog kanala modelovanim sa Gamma-Gamma raspodelom u funkciji od intenziteta signala. Rezultati su osim u analitičkoj formi, predstavljeni i grafički, u zavisnosti od odnosa srednje optičke snage na prijemu i varijanse kanalnog šuma, a za različite dužine Free Space Optical linka i jačine atmosferske turbulencije. Analiziran je kvalitet signala na osnovu srednje verovatnoće greške po bitu za slabu, umerenu i jaku atmosfersku turbulenciju.**

***Ključne reči*— ABER - Average Bit Error Rate; BPSK - Binary Phase Shift Keying; DPSK - Differential Phase Shift Keying; FSO - Free space optical; Gamma-Gamma.**

I. UVOD

Neprekidan razvoj različitih servisa bežičnih telekomunikacionih sistema, dovodi do potrebe za proučavanjem i unapređenjem njihovih performansi. Osnovni zahtevi koji su prisutni u procesu unapređenja performansi bežičnih telekomunikacionih sistema su: obezbeđivanje velikih brzina prenosa, veliki kapacitet kanala i što veći domet veze sa što manjom verovatnoćom greške.

Free Space Optical (FSO) je komunikaciona tehnologija koja omogućuje bežični full-duplex gigabitni prenos podataka u okruženju [1,2]. FSO sistemi omogućuju prenos signala sa protokom od nekoliko Gb/s, dok mikrotalasne veze omogućuju protok od nekoliko Mb/s. FSO koristi širok frekvencijski spektar, otporan je na elektromagnetne smetnje i interferenciju sa susednim kanalima (zbog dobrog definisanog uskog snopa signala bez slabljenja snage), a pruža i visok stepen bezbednosti [1,3]. FSO linkovi su kratki i kreću se do 2.5 km. Na kvalitet prenosa signala u FSO sistemima najveći uticaj imaju atmosferske prilike. Sneg i kiša znatno imaju manji uticaj na kvaltet prenosa u odnosu na atmosferske turbulencije i maglu. Atmosferski efekti na FSO sistem mogu uzrokovati pojave kao što su širenje snopa, fluktuacije intenziteta i faze signala, scintilacija [4].

Postoji više modela za opisivanje prostiranja signala u FSO sistemima sa atmosferskom turbulencijom, među kojima se izdvajaju: Gamma-Gamma, Lognormal, K-raspodela, Rician, Rayleigh i Nakagami-m koje se modeluju u funkciji od intenziteta signala ili odnosa signal-šum (SNR - Signal Noise Ratio) [5]. Model Gamma-Gamma raspodele je predložen kao pogodan matematički model za slabu i jaku turbulenciju i pruža dobre rezultate u poređenju sa eksperimentalnim [6].

Za opisivanje kvaliteta prenosa signala u FSO sistemima koriste se mnoge performanse među kojima se izdvajaju odnos signal šum (SNR), verovatnoća otkaza (OP - Outage Probability), kapacitet kanala (CC - Channel Capacity) i srednja verovatnoća greške po bitu (ABER - Average Bit Error Rate). Da bi se odredio ABER potrebno je poznavati funkciju gustine verovatnoće (PDF - Probability Density Function). PDF primljenog signala je po prirodi nestacionarna i zavisi od parametara atmosferske turbulencije, tako da ABER pruža dobru sliku o kvalitetu prenosa signala u FSO sistemima.

Za prenos signala u FSO sistemima se koristi više modulacionih formata, među kojima su najpopularniji On-Off keying (OOK), Binary Phase Shift Keying (BPSK), Differential Phase Shift Keying (DPSK) i Frequency Shift Keying (FSK) [7]. OOK format je relativno jednostavan, ali ne daje superiorne performanse. BPSK format zahteva složenu implementaciju u demodulatoru, ali daje veoma dobre performanse. DPSK format zahteva manje složeniju implementaciju od BPSK, performanse su lošije od BPSK ali znatno bolje od OOK [8]. U literaturi [3, 5-9] su predstavljene mnogobrojne statističke karakteristike signala opisanih različitim modelima raspodele i različitim modulacionim šemama u FSO sistemima. U radu [7] izračunat je ABER signala modelovanog Gamma-Gamma raspodelom u funkciji od SNR-a za više modulacionih formata.

U ovom radu određeni su analitički izrazi za ABER za Gamma-Gamma model kanala u funkciji od intenziteta signala, a pri prenosu u FSO sistemima korišćenjem DPSK i BPSK modulacione šeme. U drugom poglavlju dat je model sistema koji se razmatra i polazni izrazi za računanje ABER-a. U trećem poglavlju su predstavljeni izračunati izrazi za ABER u zatvorenom obliku za oba modela modulacionih šema. U četvrtom poglavlju dati su i komentarisani numerički rezultati dobijeni za ABER za signale modulisanim DPSK i BPSK šemama, a za različite stepene atmosferske turbulencije i dužine FSO linka. Peto poglavlje je Zaključak.

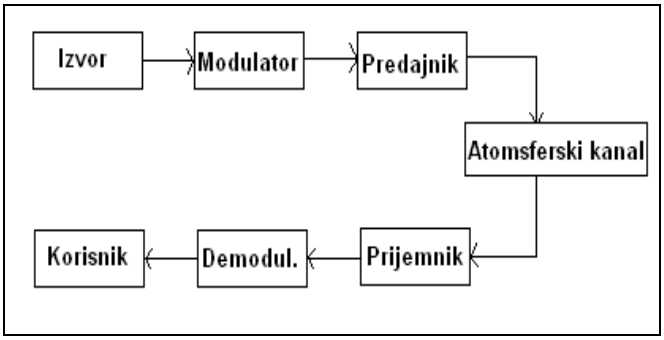
II. MODEL SISTEMA

Razmatran je tipičan FSO sistem koji se sastoji od modulatora, predajnika, atmosferskog kanala, prijemnika i demodulatora, kao što je prikazano na Sl. 1.

Signal se iz izvora dovodi na modulator u kome se primenjuje jedan obilk digitalne modulacione šeme. U ovom slučaju su razmatrane dve modulacione šeme: DPSK i BPSK. Predajnik šalje modulisani signal koji se prenosi kroz atmosferski kanal modelovan sa Gamma-Gamma raspodelom. Za oba slučaja modulacije na prijemnoj strani sistema određuje se srednja verovatnoća greške po bitu – ABER.



Sl. 1. Model FSO sistema.

Gustina verovatnoće - PDF za Gamma-Gamma model u funkciji od intenziteta je data izrazom [9]:

$$f(I)=\frac{2(\alpha\beta)^{\frac{\alpha+\beta}{2}}}{\Gamma(\alpha)\Gamma(\beta)}I^{\frac{\alpha+\beta}{2}-1}K_{\alpha-\beta}\left(2\sqrt{\alpha\beta I}\right), \quad (1)$$

gde $\Gamma(\cdot)$ predstavlja Gamma funkciju [10, Eq. 8.310.1], a $K\upsilon(\cdot)$ je modifikovana Beselova funkcija druge vrste υ-tog reda [10, Eq. 8.407]. Parametri α i β predstavljaju efektivan broj vrtloga velikih i malih razmera, respektivno. To su parametri atmosferske turbulencije koji se za propagaciju ravanskih talasa i "zero inner scale" mogu izraziti kao [9]:

$$\alpha=\left[e^{\frac{0.49\sigma_R^2}{\left(1+1.11\sigma_R^{12/5}\right)^{7/6}}}-1\right]^{-1}, \quad \beta=\left[e^{\frac{0.51\sigma_R^2}{\left(1+0.69\sigma_R^{12/5}\right)^{5/6}}}-1\right]^{-1} \quad (2)$$

gde σ_R^2 predstavlja Rojtovu varijansu koja se koristi za određivanje intenziteta optičkog signala usled atmosferske turbulencije, a definiše se kao:

$$\sigma_R^2=1.23C_n^2k^{7/6}L^{11/6}. \quad (3)$$

Parametar C_n^2 označava indeks refrakcije koji se koristi kao mera za jačinu turbulencije. Za horizontalne putanje propagacije parametar C_n^2 se smatra konstantnim sa srednjim vrednostima od 10^{-17} $m^{-2/3}$ do 10^{-13} $m^{-2/3}$ za kanale od slabe do jake turbulencije, respektivno. Parametar k je talasni broj, koji se definiše kao $k = 2\pi/\lambda$ sa talasnom dužinom λ, dok je L rastojanje između predajnika i prijemnika, odnosno dužina propagacije optičkog signala.

Srednja verovatnoća greške po bitu u zavisnosti od fluktuacije intenziteta optičkog signala kada se prenos u FSO sistemu vrši preko DPSK može se izraziti kao [11]:

$$P_e=\frac{1}{2}\int_0^\infty e^{-\frac{P_T}{\sigma_N}}f(I)dI, \quad (4)$$

gde P_T predstavlja srednju optičku snagu na prijemu, dok je σ_N varijansa kanalnog šuma. Funkcija $f(I)$ predstavlja gustinu verovatnoće (PDF) primljenog signala određene raspodele koja se koristi za opisivanje modela kanala. U ovom slučaju je u pitanju Gamma-Gamma raspodela predstavljena sa (1).

Srednja verovatnoća greške po bitu u zavisnosti od fluktuacije intenziteta optičkog signala kada se prenos u FSO sistemu vrši preko BPSK može se izraziti kao [11]:

$$P_e=\frac{1}{2}\int_0^\infty \operatorname{erfc}\left(\frac{P_T}{\sigma_N}I\right)f(I)dI, \quad (5)$$

gde je $\operatorname{erfc}(\cdot)$ komplementarna funkcija greške [10, Eq. 8.250.4], a $f(I)$ predstavlja funkciju gustine verovatnoće Gamma-Gamma raspodele.

III. ANALITIČKI REZULTATI

Zamenom PDF za Gamma-Gamma model (1) u (4) dobija se:

$$P_e=\frac{(\alpha\beta)^{\frac{\alpha+\beta}{2}}}{\Gamma(\alpha)\Gamma(\beta)}\int_0^\infty I^{\frac{\alpha+\beta}{2}-1}e^{-\frac{P_T}{\sigma_N}I}K_{\alpha-\beta}\left(2\sqrt{\alpha\beta I}\right)dI. \quad (6)$$

Kako bi se izračunao izraz u zatvorenom obliku za ABER, modifikovana Beselova funkcija druge vrste $K\upsilon(\cdot)$ se predstavlja preko Meijer G funkcije na sledeći način [10, Eq. 9.34.3]:

$$K_\nu(x)=\frac{1}{2}G_{0,2}^{2,0}\left[\frac{x^2}{4}\middle|\begin{matrix}-\\(\nu-2),\ -(\nu-2)\end{matrix}\right]. \quad (7)$$

Takođe, koristi se i relacija za transformaciju eksponencijalne funkcije u Meijer G funkciju [12, Eq. 8.4.3]:

$$e^{-x}=G_{0,1}^{1,0}\left[x\middle|\begin{matrix}-\\0\end{matrix}\right]. \quad (8)$$

Primenom (7) i (8), izraz za izračunavanje ABER-a pri DPSK (6) se svodi na:

$$P_e = \frac{(\alpha\beta)^{\frac{\alpha+\beta}{2}}}{\Gamma(\alpha)\Gamma(\beta)} \int_0^\infty I^{\frac{\alpha+\beta}{2}-1} \times G_{0,1}^{1,0}\left[\frac{P_T}{\sigma_N} I \middle| \begin{matrix} - \\ 0 \end{matrix} \right] \times \times \frac{1}{2} G_{0,2}^{2,0}\left[\alpha\beta I \middle| \begin{matrix} - \\ \frac{\alpha-\beta}{2}, -\frac{\alpha-\beta}{2} \end{matrix} \right] dI \quad . \tag{9}$$

Primenom [13, Eq. 07.34.21.0011.01] u (9) dobija se rešenje u zatvorenom obliku za ABER za slučaj prenosa korišćenjem DPSK modulacione šeme:

$$P_e = \frac{(\alpha\beta)^{\frac{\alpha+\beta}{2}}}{2\Gamma(\alpha)\Gamma(\beta)} \left(\frac{P_T}{\sigma_N} \right)^{-\frac{\alpha+\beta}{2}} \times \times G_{1,2}^{2,1}\left[\frac{\alpha\beta}{\frac{P_T}{\sigma_N}} \middle| \begin{matrix} 1-\frac{\alpha+\beta}{2} \\ \frac{\alpha-\beta}{2}, -\frac{\alpha-\beta}{2} \end{matrix} \right] \quad . \tag{10}$$

Zamenom PDF za Gamma-Gamma model (1) u (5) dobija se:

$$P_e = \frac{(\alpha\beta)^{\frac{\alpha+\beta}{2}}}{\Gamma(\alpha)\Gamma(\beta)} \int_0^\infty I^{\frac{\alpha+\beta}{2}-1} \operatorname{erfc}\left(\frac{P_T}{\sigma_N} I \right) K_{\alpha-\beta}\left(2\sqrt{\alpha\beta I} \right) dI \, . \tag{11}$$

Kako bi se izračunao izraz u zatvorenom obliku za ABER, komplementarna funkcija greške erfc(·) se predstavlja preko Meijer G funkcije [14, Eq. 06.27.26.0003.01]:

$$\operatorname{erfc}(x) = 1 - \frac{x}{\sqrt{\pi}} G_{1,2}^{1,1}\left[x^2 \middle| \begin{matrix} 1/2 \\ 0, \ -1/2 \end{matrix} \right] \, . \tag{12}$$

Primenom (7) i (12), izraz za izračunavanje ABER-a pri BPSK (11) se svodi na:

$$P_e = \frac{(\alpha\beta)^{\frac{\alpha+\beta}{2}}}{2\Gamma(\alpha)\Gamma(\beta)} \int_0^\infty I^{\frac{\alpha+\beta}{2}-1} \times \times \left[1 - \frac{P_T I}{\sigma_N \sqrt{\pi}} \times G_{1,2}^{1,1}\left[\left(\frac{P_T}{\sigma_N} I \right)^2 \middle| \begin{matrix} 1/2 \\ 0, \ -1/2 \end{matrix} \right] \right] \times \times G_{0,2}^{2,0}\left[\alpha\beta I \middle| \begin{matrix} - \\ \frac{\alpha-\beta}{2}, -\frac{\alpha-\beta}{2} \end{matrix} \right] dI \quad . \tag{13}$$

Primenom [13, Eq. 07.34.21.0012.01] dobija se rešenje u zatvorenom obliku za ABER u slučaju BPSK modulacione šeme:

$$P_e = \frac{1}{2} - \frac{1}{2\sqrt{\pi}\alpha\beta\Gamma(\alpha)\Gamma(\beta)} \frac{P_T}{\sigma_N} \times \times H_{3,2}^{1,3}\left[\left(\frac{P_T}{\alpha\beta\sigma_N} \right)^2 \middle| \begin{matrix} \left(\frac{1}{2},1\right), \ (-\alpha,2), \ (-\beta,2) \\ (0,1), \ \left(-\frac{1}{2},1\right) \end{matrix} \right] \tag{14}$$

gde $H_{p,q}^{m,n}(\cdot)$ predstavlja Fox H funkciju, koja je, ustvari, generalizacija Maijer G funkcije. Fox H funkcija se u specijalnom slučaju svodi na Maijer G funkciju [13, Eq. 07.34.26.0008.01].

IV. NUMERIČKI REZULTATI

Za potrebe numeričkog proračuna posmatran je FSO sistem na talasnoj dužini λ = 875 nm. Razmatrana su tri tipa atmosferske turbulencije: slaba, umerena i jaka, sa indeksima refrakcije $C_n^2 = 6 \cdot 10^{-15}$ m$^{-2/3}$, $C_n^2 = 2 \cdot 10^{-14}$ m$^{-2/3}$ i $C_n^2 = 1.2 \cdot 10^{-13}$ m$^{-2/3}$, respektivno. Posmatrana su dva slučaja za rastojanja prijemnika od predajnika L=1 km i L=2 km.

U Tabeli 1 date su vrednosti parametara α i β dobijene za slučajeve koji se razmatraju.

TABELA I
VREDNOSTI PARAMETARA ATMOSFERSKE TURBULENCIJE.

C_n^2		$6 \cdot 10^{-15}$	$2 \cdot 10^{-14}$	$1.2 \cdot 10^{-13}$
L=1 km	σ_R^2	0.23	0.77	4.65
	α	10.28	4.80	4.49
	β	8.77	3.08	1.25
L=1.5 km	σ_R^2	0.48	1.63	9.79
	α	6.05	4.02	5.64
	β	4.47	1.89	1.10
L=2 km	σ_R^2	0.82	2.76	16.58
	α	4.68	4.07	6.85
	β	2.93	1.47	1.05

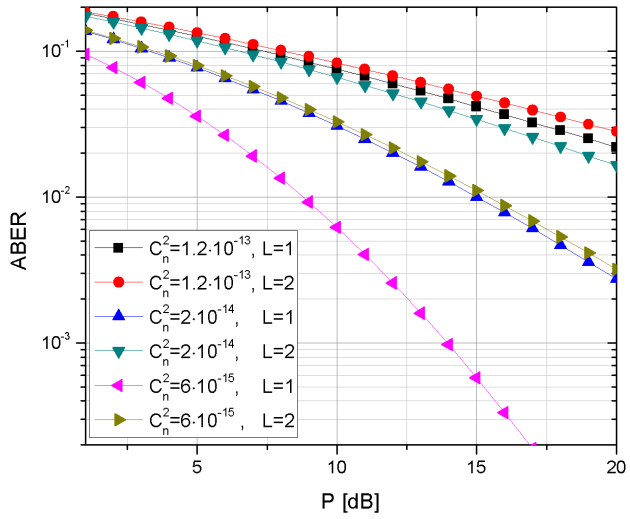
Na osnovu dobijenih analitičkih izraza u zatvorenom obliku za ABER pri DPSK i BPSK modulaciji, (10) i (14), respektivno, predstavljeni su grafici promene ABER u zavisnosti od odnosa $P = P_T/\sigma_N$. Grafici za ABER Gamma-Gamma modela kanala za DPSK i BPSK modulaciju su dati na Sl. 2 i Sl. 3, respektivno.

Sa datih slika se može videti da sa porastom odnosa P dolazi do smanjenja srednje verovatnoće greške po bitu. ABER brže opada za niže stepene atmosferske turbulencije u odnosu na jaku turbulenciju. Sa povećanjem turbulencije dolazi do povećenja ABER-a. Takođe, sa Sl. 2 i Sl. 3 se može videti da veće vrednosti dužine FSO linka dovode do povećanja ABER-a.

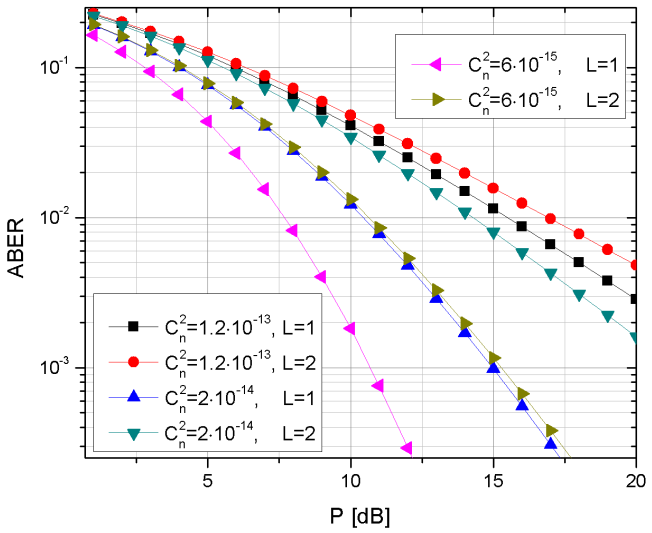
Kod DPSK modulacione šeme vrednosti ABER-a su reda 10^{-1} i kreću se sve do P > 20 dB pri jakoj turbulenciji, pri

umerenoj turbulenciji istog reda su do 15 dB, a pri slaboj turbulenciji do 9 dB. Da bi se ABER smanjio na red 10^{-3} potrebna je znatno viša snaga, za jaku i umerenu turbulenciju znatno više od 20 dB. Za slabu turbulenciju je potrebna snaga od 14 dB kako bi se ABER spustio na red 10^{-3}.

Takođe, može se videti da je srednja verovatnoća greške po bitu kod BPSK modulacije reda 10^{-1} do snage od 15 dB za jaku atmosfersku turbulenciju, a za umerenu turbulencije je do 10 dB. Kod slabe turbulencije ABER je reda 10^{-1} do snage od 7 dB. ABER prelazi iz reda 10^{-2} u red 10^{-3} kod jake turbulencije tek za $P > 20$ dB, kod umerene turbulencije za 15 dB, a kod slabe turbulencije za 12 dB.



Sl. 2. ABER za Gamma-Gamma model kanala pri DPSK modulaciji.

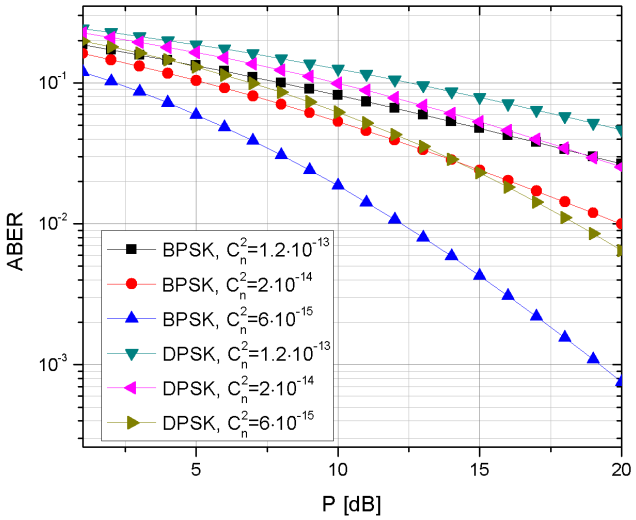


Sl. 3. ABER za Gamma-Gamma model kanala pri BPSK modulaciji.

Na osnovu dobijenih rezultata za srednju verovatnoću greške po bitu može se zaključiti da se bolje karakteristike prenosa dobijaju za BPSK modulacionu šemu. Kod BPSK modulacije je potrebno mnogo manje snage (tj. odnosa srednje optičke snage na prijemu i varijanse kanalnog šuma) nego kod DPSK modulacije da bi se dobio isti red ABER-a.

Na Sl. 4 je prikazana promena ABER-a u funkciji od $P = P_T/\sigma_N$ usled slabe, umerene i jake turbulencije za DPSK i BPSK modulacionu šemu. Rastojanje od predajnika do prijemnika iznosi L=1.5 km.

Sa Sl. 4 se može videti da se veće vrednosti ABER-a dobijaju korišćenjem DPSK nego BPSK modulacione šeme. Odnosno, BPSK daje bolje performanse FSO sistema. Takođe, može se videti da kod BPSK, ABER znatno brže opada sa porastom snage nego kod DPSK modulacione šeme. Pri višim odnosima $P = P_T/\sigma_N$ postoje dominantnije razlike ABER-a za DPSK i BPSK modulacionu šemu. Ta razlika je veća za niže stepene atmosferske turbulencije, dok je za jake atmosferske turbulencije razlika približno konstantna duž celog opsega odnosa $P = P_T/\sigma_N$.



Sl. 4. Poređenje ABER-a za DPSK i BPSK modulaciju.

V. ZAKLJUČAK

U radu su predstavljene i analizirane dobijene vrednosti ABER-a za signale modulisane DPSK i BPSK modulacionom šemom koji se prostiru kroz FSO kanal modelovan sa Gamma-Gamma raspodelom u funkciji od intenziteta. Dobijeni rezultati su grafički predstavljeni kako bi se video uticaj slabe, umerene i jake atmosferske turbulencije i dužina FSO linka na kvalitet prenosa signala.

Koristeći predstavljene rezultate može se predvideti ponašanje realizacija FSO sistema za različite modele modulacionih formata i u različitim propagacionim okruženjima, što omogućava projektantima sistema mobilnih prenosa da za željene performanse sistema naprave racionalna sistematska rešenja.

ZAHVALNICA

Ovaj rad je rađen u okviru istraživačkih projekta Ministarstva nauke i tehnološkog razvoja Republike Srbije: TR32023 i TR35026.

ABSTRACT

In this paper, the average bit-error rate of the signal in the free-space optical system modulated with differential phase shift keying and binary phase shift keying scheme is calculated and analyzed. The average bit-error rate is determined in the case of an atmospheric channel modeled with a Gamma-Gamma distribution in function of signal intensity. The results are presented both analytically and graphically, depending on the rate of the average received optical power and the channel noise variance for different lengths of the free-space optical link and the strength of the atmospheric turbulence. The quality of the signal was analyzed based on the average bit-error rate for weak, moderate and strong atmospheric turbulence.

Average Bit Error Rate at Modulated Signal Transmission in FSO System

Achilles - MARS: Modular Chess System

Vladan Vučković

***Abstract*— This paper has intention to describe the original construction and infrastructure of the modular chess system Achilles (version 2019) - MARS consisting and connecting several complex subsystems. The central part of this system is high-performance 30 million per position distributed chess engine Achilles 2019. The system MARS is an old system renewed in 2014 and now connected to Achilles as the interactive module and option to play against professional chess players.**

***Index Terms*—Artificial Intelligence, Computer Chess, Electronics.**

I. Introduction

During May, 1997 the field of research in artificial intelligence happened to be an important event. In a direct duel IBM chess supercomputer Deep Blue beat world champion grandmaster Garry Kasparov. It was the first event of its kind, the first sign of possible machine intelligence supremacy over the human intelligence in certain specific areas of human activity. Considering the doubts about the result, many researchers in this field started to scrutinize this very interesting field. After the match, IBM showed no more interest in computer chess, so there were no more ways to test this chess supercomputer and its chess power.

IBM Deep Blue vs. Kasparov rematch has never happened again. After 1997, some researchers started to construct machines with intention to repeat the success of IBM Deep Blue. A joint feature of many of these projects is the orientation of standard PC technology and the X86 machine instruction set as the basis of the chess computer. With intensive development of multithread and multicore technologies which enable the use of internal parallelism in the CPU has become possible to construct programs with grandmaster chess rating on standard PC machines. On the other hand, local area network PC clusters opened up new possibilities of distributed processing data and thereby enhanced power compared to the software on a single processor. At any rate, the simultaneous development of technology, accelerating CPU speed and architecture in the sense of parallelization has brought huge benefits to computer chess.

Development of the FPCGA logic circuits opened the possibility to implement some critical parts of chess algorithms in hardware, which is largely utilized in the system Hydra. Hydra was a leading chess system in the certain period of development, and its successes were crowned with a convincing victory over the grandmaster Michael Adams, with score of 5.5 - 0.5 (2005). The direction to which lead the combination of PC architecture and FPCGA hardware circuits with this system became very popular. However, similar to the IBM Deep Blue, the Hydra proved to be a complex and expensive system for development and maintenance. PC technology which primarily have processing power only concentrated in CPUs, has considerably more intense development comparing to FPCGA, so it was proved in a short time that software modifications are significantly faster than hardware. After a while, mainstream direction for the optimal chess system was entirely based on multiprocessor and network PC technology. Today's computer chess technology development especially in the ICGA computer chess championships shows the absolute domination of this direction. Also, the modern PC chess engines have reached the grandmaster playing strength.

However, 1997 chess match was undoubtedly the initial for the author, and gave the directions for further research and the start of working on creating its own system of chess grandmaster strength. To start the project of such great scale with no initial material resources and organized institutional support, or opportunities for fast commercialization, for an individual seemed like an insurmountable task. However, in the laboratory environment, with PII 400 Mhz, somewhere around 2000 year, author had begun this extensive work. In subsequent years the author has developed all of the components for the complex cluster chess system, the entire structure, and application and communication software. Since 2001, when the program *Geniss Axon* debuted on single processor, the system evolved in parallel multiprocessor program *Achilles* and in January 2007 definitely overcome the chess grandmaster strength and scored its first victory against a grandmaster in the official tournament. If we look at the ELO rating directly, Axon-Achilles progresses with 1400 ELO points in its 15 years of development.

In the meantime, the program has played a lot of official matches and tournaments, with rating FIDE chess players, connected to the world's largest chess server *Chessbase* and through it have played 3 *FreeStyle* tournaments. At last tournament, Achilles haven`t lose a match (with one win and all others matches draws). It is also important to mention the collaboration with German company *Arena* following the authors PhD theses, which was defended on 24.10.2006, in the field of artificial intelligence and computer chess – the first of that kind in author's country.
The next big event was a match against grandmaster Igor Miladinovic in July 2007, which ended with the 3.5-0.5 victory of Achilles system. The author continued developing his cluster chess system to the newest version which defatted GM Miroslav Miljkovic in two games TV match (1.5-0.5).

This paper has intention to describe the original construction of modular cluster chess system Achilles (version 2019) consisting and connecting several complex subsystems, including MARS. The system core is high-

Vladan Vučković is with the Faculty of Electronic Engineering, University of Niš, 14 Aleksandra Medvedeva, 18000 Niš, Serbia (e-mail: vladanvuckovic24@gmail.com; vladan.vuckovic@elfak.ni.ac.rs).

performance 30 million per position distributed chess engine and details of its construction is presented in Section 2. The second module is presented in Section 3 - named MARS. It is an old system renewed in 2014 and now connected to *Achilles* as the module and option to play against professional chess players. This paper will be concluded with final remarks.

II. ACHILLES 2019 SYSTEM

Nowadays, there are a set of standard algorithms including MiniMax, Alfa-Beta, Negamax, PVS, Null Move for constructing powerful chess engines [1]. Also, there are other supporting and background algorithms responsible for maximizing the engine play strength. Common feature of these algorithms is that all of them have MiniMax procedure as basic code. Also, there are some pioneering efforts to mimic the grandmaster way of thinking in chess [2].

By definition the MiniMax function is recursive search-tree algorithm supporting the artificial decision-maker in logic games generally. Using algorithms to search that content implementing MiniMax procedure, the value of the terminal nodes is prolonged in reverse direction - through the tree to the root node. Even in the earliest stages of computer chess research a significant negative effect that may occur in the final stage of evaluation nodes was observed. This effect is called *horizon effect* because of fatal errors that could be generated trying to evaluate terminal dynamic positions [3].

To minimize time needed for calculation of the complex tree search in parallel computer environment, **we introduce the method of the candidate moves analogue to the human thinking process in chess.** Simplified, we reduce the set of playable moves at the root node only to few moves using the complex heuristic. Then the parallel machines process only the sub-trees generated from these moves.

The search trees are almost completely independent, in order that is possible to implement the parallel search for each candidate move using the authors' Achilles cluster chess engine as the basic infrastructure [4]. This implementation accelerates the complete process and increases the depth of the searching at the same time.

A. The Parallelization Method Using Original Methods Of The Candidates Move

Transition on working in multiprocessor environment led to the need of solving the sequence of problems on conception, implementation and communicational levels [5],[6]. The use of the parallel system, which consists of gathering of standard single processor PC machines connected by LAN network, implements new solutions which are not covered enough in the literature.

Exploring this area, the author discovered the new theoretical conception which was the base for making a completely new parallelization algorithm on distributive machines using vector parallelization methods. If we observe the basic chess engine plan [5], which is covered on multiple levels in this paper, we can register clear separation of 3 phases: the main, ALFA_BETA/PVS/null-move algorithm [7], relies on quiescence tracer terminal knots, which invokes evaluator in its every knot.

(basic tree >> quiescence searcher >> evaluator)

In fundamental plan the linear conception of the chess engine is clearly visible and that conception is actually based on the reduction principle – the basic position is reduced through the main tree to the sequence of the terminal nodes, which are further reduced with quiescence procedure which then declines to the sequence of static nodes which are evaluated.

But, the human chess master has different approach:

(basic tree >> candidate move selection >> calculation of limited selected lines)

Our new conception, that follows last direction, can be efficient only if new processors are used in different lines - therefore in multiprocessor environment. The main problem here lies in the fact that communication problems approximately grows with the square of number of processors and that is not favorably. On the other hand, according to the suggested new conception operation of all processors is undependable and asynchronous in a way that from a hardware perspective it is only necessary to establish a classic distributive network between the processors, without the need for multiprocessor motherboards.

B. Achilles – parallel chess system structure

Achilles chess system represents the parallel system of the new generation which is based on distributed parallelization with preselecting of candidate moves [6]. The first version, developed in 2005, consisted of 8-processor system, based on AMD X64 machines, operated on 1,8 Ghz and on Axon II program in separate knots, generates over 95% of cases, one external vector level, which means intensification the basic machines play level in practical game for over 200 ELO points. The parallel machine plays on the level which can achieve ratings of over 2800 ALO points in matches with shorter time control (up to 25 minutes per player). From the theoretical aspect, if the network with 82=64 processors would be at disposal, a machine with 2 external levels could be implemented by the same method of parallelization, so that increase of the power in relation with the rating of the Axon II program would be approximately 400 ELO points; this means that a parallel machine of such type could play with strength of over 3000 ELO points. The visual design of the Achilles system which performs distributed parallelization is shown in Fig. 1:

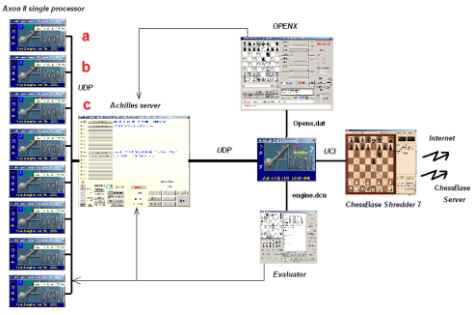

Fig. 1. Achilles engine diagram.

The connection with separate Axon II machines which operate on single processor systems is performed via LAN. This form of communication and synchronization [8] allows

that machines do not have to be on the network with the same IP address, which also allows practical possibility for development of parallel systems with denary processors (Fig.2). Solving communicational problems for Achilles program system, the author conceived a universal system for coded chess transfer using standard UDP (*Universal Datagram Protocol*) protocols.

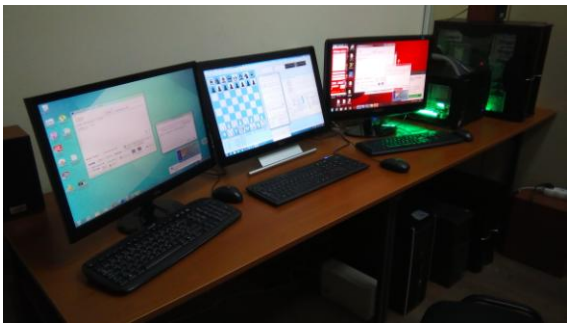

Fig. 2. Internal LAN connected Achilles cluster core.

C. Candidate moves distribution

In Achilles.2019 parallel infrastructure, candidate move principle implementation is rather simple. For example, if we use the game tree with three candidate moves (a, b, c) from the MiniMax tree root are simply redistributed to the first 3 nodes in Achilles system (Fig.1.).

In previous section we analyzed the game tree, so all three branches following the candidate moves could be calculated independently and concurrently. The acceleration is almost linear, depending on position. The Achilles could run concurrently many of candidate moves depending on the numbers of physical PC nodes in system [9]. The system GUI presented in Fig.3 is able to run up to 5 candidate moves in parallel.

Fig. 3. Achilles GUI with cluster control panels.

III. CHESS DEMONSTRATION SYSTEM MARS

Electronic devices for displaying scores in many sport branches, including athletic, swimming; winter and other sports which are in connection with surveying first appeared in the last quarter of the 20th century, based on technology to develop to updated digital electronics nowadays.

Approximately at the same time, the idea about automatic translation and demonstration in real time chess game, from the stage of important matches was born. On the first few there was an electronic chess semaphore supplied by sensor table. It was used at the world championship match Spassky–Petrossian in Moscow, 1969, and it was designed by Hungarian engineer Barfai. At the same time this match was demonstrated in Central Chess Club on one other board, designed by prof. Gleb Hlebutin from The Perm University. Displayed chess pieces between two boards were very different, much better than on the Russian display, but Hungarian system was supplied by the quickest sensor table.

After the match SSSR–The Rest of the World, organized in Belgrade 1970, an original idea to design chess demonstration board by the same principle as composition of the digits on the 7-segments deflector was born. We have found acceptable solution for chess esthetics and technology reproductive in one 10-segments deflector rosette. See down shown figures; each segment is supplied by two colored bulbs to represent white and black piece symbols (Fig.4).

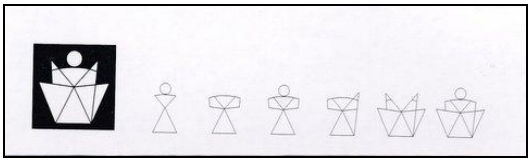

Fig. 4. Original solution for MARS demo-board pieces.

The first experimental used during the match Korchoy–Spassky was very successful, but for my assistants and me here at Electronic factory in Nish, Serbia, a problem to find satisfactory solution for sensor chess table appeared. The experiment have lead from different essays – resistance squares, read-relay, Hall sensors and inductive coupled oscillators circuits in the end. One of the main conditions was not to attain any difference between ordinary wooden chess pieces and at the same time provide invisible built-in sensors. The same rule was applied in designing of the table, respecting FIDE rules of proportion pieces diameter on square base – approximately 2 : 3. At the same time it was presented by newspaper and announced in one sensor TV chess demonstration system in Central Italian Chess Club in Milan, designed by Dottore De Bellis. Subsystems of the MARS (*Multifunctional Automatic Running Chess System*) are:

1) *Display*, implemented in classical track bulb technology, size 2 by 2 meters on pedestal with black and white collapsed times and move counters, and in-built power sources for energetic and electronic circuits.

2) *Tournament chess wooden table* with sensors manufactured by first class wood and well contrasted veneer in accordance with FIDE rules, supplied with hidden sensor system for piece recognition, control card and linked to control unit; and PC-486 as the Control Unit, with additional A/D convertor, as well as conventional SW for testing, initialization system and the main function – transmission and displaying tournament chess game in real time and authentic tournament conditions. There are possibilities for immediately replaying and printing games. MARS system has been well known for forty years now and it had been used on many chess events, including two matches at The Word Championship and two Olympics, too.

A. Conception of the digital sensor

The recognition of twelve (6 white + 6 black) different chess pieces is based on twelve resonant frequencies arranged by oscillator circuits built in each chess piece. The same kind of pices is trimmed at the same frequency. The

experiment defined range for the given problem conditions is from 490 to 610 kHz, by increment of 10 kHz. This is the most linear part of the frequency U(f) characteristics for all twelve piece oscillators and sensors matrix 8 x 8 squares positioned under chess table at distance of 7±0.3 mm. The best electromagnetic energy interchange between passive oscillators and sensors happens when the both spools are of the similar spool inductivity (in our case 1 mH approximately). Oscillators in the pieces are designed by high frequency tin phone wires on self keeping spool with one core in the middle and soft ferrite core for resonant frequency trimming. Sampling rate is 2000 per sec or 3 moves per sec. During experiments with different models of spool a few problems appeared. The first one was the impossibility of manufacturing circuits with similar varying characteristics. This problem was solved by careful sensor selection and finding the best position on table matrix to avoid any interferences. The second problem was to solve recognitions gaps between neighboring squares. The temperature stabilization of each passive oscillator in the chess pieces was of the greatest importance, because resonant frequencies depend a lot on temperature stabilization. The proper solution was found by ceramic heat stabilized capacitor, all heat isolated by wax. The last, but not the simplest problem appeared in reproduction of several hundreds of chess pieces in low series laboratory manufactured.

One of the best SW improvements was designed with one initial system utility, which assured 12 x 64 referent levels for all different pieces and chess table square, saved and simply modified by system on reset procedure. This utility is provide by real-time control of this referent level matrix to avoid unregistered unstable signals and blinking of the chess symbols on PC screen and simultaneous on large display, too. The inductive coupled sensor schema, showed bellow (Fig.5):

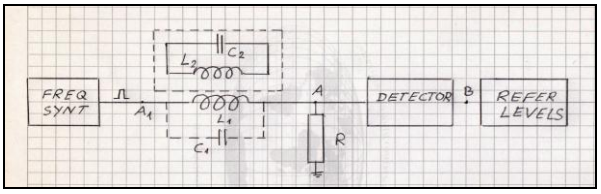

Fig. 5. Original sensor solution for MARS chess board.

IV. Conclusion

This paper presented some of original improvements embedded into the basic MiniMax procedure with direct implementation in author's Achilles computer chess program. Parallel version of the MiniMax procedure, based on candidate move principle, improves basic function and increases the total playing strength of the chess engine. There are some similar theoretical approaches, but according to the author's knowledge, there are no published data for the implementation of the results.

This idea exploits the independences in game tree calculating, as shown in the second Section, to accelerate the game tree calculation in distributed environment. To simplify, after determination of the candidate moves, all of them are distributed to different nodes in Achilles cluster.

After that, the game tree for each candidate move is calculated concurrently. This method is similar to human grandmaster way of thinking and makes decisions during the game of chess. The solution is proved in direct implementation in *Achilles* tournament practice (Fig.5). The future prospect will be to increase the amount of embedded chess knowledge in the phase of candidate move generating.

According to some tests, parallel system *Achilles.2019* has ELO rating above 3100. According to modern tendencies in computer chess, there is plenty of room for further improvement of the system by adding more processors up to maximum capacity, increasing the speed of operation of basic modules using faster multiprocessors, complete switching to 1Gbit network, and improving the level of the *Axon.2019* software, especially its evaluation function.

The Potential of Using EEG Data in Evaluation of Visual Short-Term Memory Test Results

Milos Antonijevic, Miodrag Zivkovic, Sladjana Arsic, Aleksandar Jevremovic

***Abstract*— In this research we tried to determine the possible correlation between participant' emotional state while doing the Visual short-term working memory test in regard to the test results he achieved. We have analyzed data gathered from thirteen subjects doing the test with two images. First results show that, by analyzing EEG data, we can achieve accuracy of 61.66% in classifying instances in regard to Correctness of the answer class. Also, by comparing overall changes in participant's emotional state, we were able to conclude that there is a significant decrease in stress, engagement, relaxation and focus when participant switched from viewing the image to answering the questions.**

***Index Terms*—visual short-term memory, human-computer interaction, classification, EEG.**

I. Introduction

The main goal of this research is to determine the possible correlation between participant' emotional state while doing the Visual short-term working memory test in regard to the test results he achieved.

For the purpose of this paper, we have gathered data of human-computer interaction by using two sensors: EEG device and computer mouse. For synchronized sensor data processing we used developed HCI-MAP (Human-computer Interaction Monitoring and Analytics Platform) architecture. In this paper, we described our first results of the quantitative and qualitative analyses based on EEG data.

Visual short-term memory (VSTM) is defined as the ability to remember a small amount of visual information, such as colours, shapes and similar, during a short period of time [1]. The multicomponent model of working memory was introduced by Baddeley and Hitch [2,3]. The latest version of the model [4] consists of three systems, which include components for keeping and processing information.

Neuropsychological assessment enables the testing and assessment of VSTM. The most frequently used practices include classic direct and indirect numbers test from Wechsler's scale, NEPSY test by Korkman, Kirk and Kemp (from 1998), continuous performance test (CPT), memory malingering test (TOMM), visual organization test (VOT), test of variables of attention (TOVA) and Tower of London test. These tests measure not only visual short-term memory, but also short-term memory, reaction speed, working memory, visual scanning, the perception of the environment, remembering of the context, naming, distinguishing and speed of data processing [5].

VISMEM is very important and frequently used test and it is created using the classic TOMM test [6]. The test consists of showing an image to the subject for the limited period of time. During this time, the subject has a task to look at the image and memorize the context and remember as many details from the image as possible. After the given time expires, the image is removed and the subject gives answers to different questions about the image [7].

Electroencephalography (EEG) is a non-invasive method of tracking changes in electrical voltage of brain neurons during a defined time interval. EMOTIV EPOC+ device [8] was used for measuring the variability of emotional characteristics of the subject, depending on the changes in the surrounding environment. The manufacturer has developed the algorithms for extracting values of six emotional states (Interest, Engagement, Excitement, Stress, Relaxation, and Focus) from raw EEG data that we used in this research [9].

II. Related Work

In the study in [10], the authors investigated the emotional states of students, represented in the form of frustration and excitement, that occurred as a result of feedback information gathered from intelligent tutoring systems (ITS). By analysing the obtained data, the authors developed a system that enabled student emotions to be anticipated and the feedback information to be modified accordingly. Similarly, emotional reactions to different visual stimuli were examined in two independent works [11,12].

The goal of the experiment described in [13] was the detection of the level of pleasure. The authors also tested a method for correcting the robot's behaviour in order to increase the pleasure level. Although the experiment was carried out on a small number of participants (four males), a correct classification was achieved in an average of 79.2% of cases.

In one of our papers, we described some steps towards applying artificial intelligence and EEG signals for the improvement of electronic assessments [14]. The first analyses point to the possibility of using certain question types in electronic tests in order to influence the psychological state of students during assessments. For example, by inserting "funny" questions with one obvious correct answer,

M. Antonijevic is PhD Candidate with the Informatics and Computing Department, University Singidunum, Danijelova 32, 11000 Belgrade, Serbia (e-mail: mantonijevic@singidunum.ac.rs).

M. Zivkovic is with the Informatics and Computing Department, University Singidunum, Danijelova 32, 11000 Belgrade, Serbia (e-mail: mzivkovic@singidunum.ac.rs).

S. Arsic is with Academy of Vocational Studies, 35230 Cuprija, Serbia (e-mail: sarsic101@gmail.com).

A. Jevremovic is with the Informatics and Computing Department, University Singidunum, Danijelova 32, 11000 Belgrade, Serbia (e-mail: ajevremovic@singidunum.ac.rs).

this system can decrease the students' stress. Furthermore, the most interesting questions are the easy ones, while the focus of the student can be increased by using "impossible" questions with no correct answers.

III. Applications

For collecting and synchronizing data from different sensor devices and client applications, in this research we used HCI-MAP (Human-Computer Interaction and Monitoring Platform) platform [15]. We have developed a separate application for each sensor with the possibility to send data to the platform over the HTTP(S) protocol and the HCI-MAP API. Each application is implemented as a web application which uses the same interface for sending data (Fig. 1).

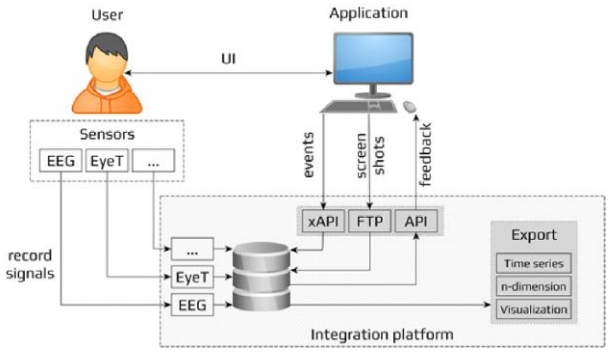

Fig. 1. The HCI-MAP architecture.

HCI-MAP platform is used for synchronization of gathered data from client applications and various sensors; data aggregation and processing in real time; and returning of obtained results in suitable formats for further analysis by computer or interpretation by humans. Besides the sensors, using the same interface, a platform can receive information from user applications.

VSTM application has been implemented as a modern interactive Web application. Used technologies include HTML5, CSS and JavaScript. The application contains three main sections: initialization screen, a screen with the image to be memorized and questions. User has a limited time to remember as many details from the image as possible. After the available time expires, the image will be removed and questions will be shown (Fig. 2).

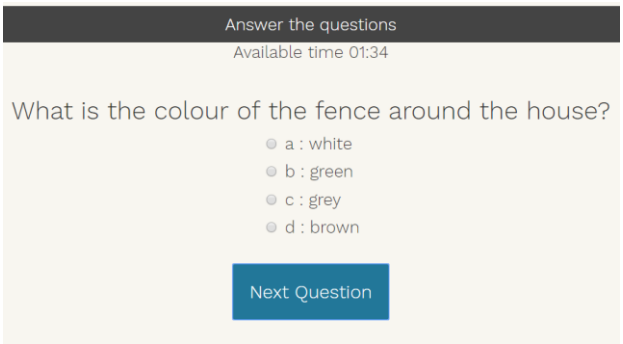

Fig. 2. Screen with a question in VSTM application.

IV. Experiment

Thirteen subjects, divided into two groups, took part in the experiment. Each subject was presented with two images during two recording sessions, without taking a break. The first image is shown in an isolated environment, and the second image is shown in front of the audience. The first group of subjects was presented with image A as the first image, and image B as the second image. The second group of subjects was presented with reversed order of images (image B first, image A second).

Fig. 3. Participants wearing EEG equipment during the experiment.

At the beginning of the testing, the subject is presented with an image for one minute. After that, the subject has two minutes to answer 10 questions about image details.

Due to a communication problems, we have 23 valid data sets for analyses (eleven full sets and one containing partial data from participant 12 when viewing image A second in a row).

V. Results

Gathered data was organized by participant number, question number, and correctness of the answer.

In this paper, we tried to classify data using Correctness of the answer class. In this case, an instance can belong to the one of three classes - viewing the IMAGE, correct answer (TRUE) or wrong answer (FALSE). We did not use *time duration* feature in any of classification algorithms because the time interval for viewing the image (which is 60 seconds) is greatly bigger from the intervals of answering the questions. It should also be noted that we are dealing with imbalanced dataset (number of instances belonging to different classes is significantly different).

Having that in mind, it can be said that there are not any significant classification results achieved using *Correctness of the answer* attribute as class. The best result is achieved by using **K-nearest neighbors classifier**, **with k = 3**, where we have more correct than incorrect classifications in two classes - IMAGE and TRUE (Table 1), while with all other used classification algorithms there are more correct than incorrect classifications in only one class (TRUE). K-nearest neighbors

classifier gives 61.66% of correctly classified instances using cross-validation and 61.63% of correctly classified instances with 66% training set.

TABLE I
CORRECTNESS OF THE ANSWER, K-NEAREST NEIGHBORS CLASSIFIER (K = 3) RESULTS

A. Cross-validation

IMAGE	TRUE	FALSE	<-- classified as
16	5	2	IMAGE
5	119	32	TRUE
3	50	21	FALSE

B. Training set with 66% of data

IMAGE	TRUE	FALSE	<-- classified as
4	1	1	IMAGE
3	43	12	TRUE
2	14	6	FALSE

After performing the classification attempts, we have tried to analyze the changes in emotional state features by doing qualitative data analysis. When analyzing EEG data, we have tried to determine the relation between individual feature and the class by comparing its average values for each of three possible classes (IMAGE, TRUE, FALSE). After that, we have selected the features with the biggest difference in average values and tried to group them based on belonging to the same emotional state. We made a comparison between the class *Viewing the image*, on one side, and *Wrong* and *Correct answer* classes on the other (Table 2).

TABLE II
COMPARISON OF FEATURE' AVERAGE VALUES FOR CLASS VIEWING THE IMAGE AND CLASSES WRONG AND CORRECT ANSWER

Average Difference in %	Feature	Emotional state
-32.28	Stress Max	STRESS
-25.29	Eng Max	ENGAGEMENT
-15.85	Rel Max	RELAXATION
-13.58	Foc Max	FOCUS

The results from the Table 2. show that there is a significant decrease in **stress**, **engagement**, **relaxation** and **focus** when the participant switched from viewing the image to answering the questions. For example, maximal stress value was, in average, 32.28% higher while user was viewing the picture.

VI. CONCLUSION

For this paper, we gathered data from thirteen subjects and two used sensors for HCI data collection - EEG device and computer mouse. Raw EEG data was then transformed to six emotional states (Interest, Engagement, Excitement, Stress, Relaxation, and Focus) that were used in different classification attempts in regard to the *Correctness of the answer* class. The best result is achieved by using K-nearest neighbors classifier with the accuracy of 61.66%.

In our qualitative analysis, we were able to conclude that there is a significant decrease in (average) stress, engagement, relaxation and focus when participant switched from viewing the image to answering the questions.

Our future work will include both quantitative and qualitative analysis of possible correlation between EEG data and the order of the image that was presented to the user, i.e. if the user was in the presence of the audience during the testing or not. Also, we will try to determine if there is correlation between participant's emotional state and the type of the image he was viewing during the test (image A or image B).

Deep Learning in Development of Model-Dependent Diagnostic: Recognition of Detector Characteristics in Measured Responses

Miroslava Jordović Pavlović, Dragan Markushev, Slobodanka Galović, Marica Popović

***Abstract*— Deep learning has successfully been implemented in various domains, including photoacoustics. The collection and creation of massive datasets creates new possibilities. Deep learning methods, when applied on massive datasets, are able to extract very useful patterns. This can lead to solutions to many problems. In this paper we discuss and develop deep learning application for the recognition of a detector influence pattern on recorded responses of a measurement chain in model-dependent experimental measurements. This enables the fast calibration of the method, which is necessary for its further application in the characterization or scanning of the examined objects with satisfactory accuracy. Frequency gas-microphone photoacoustic measurements were taken as the case study. The paper presents three models for the solution of instrument influence on true signals in photoacoustic experiments. We analyze the influence of neural network depth and the number of outputs on the prediction accuracy, and then we discuss the choice of the optimal solution.**

***Index Terms*—Deep learning; regression; massive dataset; photoacoustics; model-dependent diagnostic; microphone.**

I. INTRODUCTION

Deep learning is the area of machine learning which has seen the most intensive growth in the past few years. By bringing new techniques, algorithms and implementations, deep learning has produced impressive results. These methods have dramatically improved the state-of-the-art in speech recognition, visual object recognition, object detection, and many other domains [1]. Generally, deep learning is applicable in many fields of science, medicine, business, and in other real-world problems. Deep learning algorithms can potentially be used in every field of medicine, from drug discovery to clinical decisions. In those applications, like many others, deep learning is far ahead of other machine learning algorithms. Deep convolutional networks have been proven as a good solution for medical image classification, localization, detection, segmentation, and registration [2].

Deep learning in bioinformatics has many applications: sequence analysis, biomolecular property prediction, biomedical image processing and diagnosis [3].

Another reason for the present and future successes of deep learning is that it requires very little engineering by hand, so it can easily take advantage of increases in the amount of available computation and data. Deep-learning methods are representation-learning methods with multiple levels of representation, obtained by composing simple but non-linear modules, each of which transform a representation at one level (starting with the raw input) into a representation at a higher, slightly more abstract level. With the composition of a significant number of such transformations, very complex functions can be learned. Methods may very well discover interesting structures in large datasets [1][4][5]. Those are the reasons why they are very suitable for application in many domains.

This paper will show that deep learning is applicable in model-dependent diagnostic techniques with no calibration method, which enables the exclusion of measurement chain influence and in particular the influence of the microphone characteristics. This influence is not at all simple and eludes the usual kinds of differential calibration and standardization on the referential sample. Having said that, characterization done by those methods cannot give the exact properties which could satisfy fundamental scientific research. The case study was carried out for gas-microphone frequency photoacoustic technique. Justification of deep neural network application in photoacoustics relative to shallow neural networks is presented.

II. DEEP LEARNING IN PHOTOACOUSTICS

Physical parameters that configure in the physical model of the photoacoustic response are mostly nonlinearly dependent, very often with unknown and unavailable characteristics of the transformation process of the examined physical quantity in the electric signal. It is expected that the development and application of neural networks in photoacoustics and all similar model-dependent methods which use detectors of a common purpose is a good decision because deep learning is able to

approximate any nonlinear mapping with very high accuracy and reliability, and in that manner recognize and extract pattern of influence of individual parameters on true signal enabling calibration of the method. Also, classification models of different nonlinear mappings could be designed with very high accuracy using deep neural networks, which are applicable in the selection of different source influences on the true signal.

Neural networks are present in photoacoustics and other model-dependent measurement techniques which have been developed for scientific research and biomedical diagnostics for a very long time.

In [6], a shallow neural network is used for the reconstruction of the optical profile of optically gradient materials based on the frequency, magnitude and phase of the measured PT (photothermal) response.

In paper [7] shallow neural network with forward signal propagation was designed and used to simultaneously determine main physical parameters, such as: thermal diffusivity, thermal expansion coefficient and thickness, from transmission, frequency modulated photoacoustic response of the sample.

Examples of deep learning application in photoacoustics for the past few years are numerus.

Paper [8] presents deep convolutional network application for noise removal in photoacoustic recognition of images. Photoacoustic imaging is a method for the visualization of point-like targets. Using this method, detection of anatomical features or metal implants in the human body is possible, which can further be used in cancer detection, monitoring blood vessel flow, detecting and guiding surgeries, etc. Laser beam transmission in the presence of highly echogenic structures has consequences for the creation of a reflection artifact that may appear as a true signal. Deep convolutional networks turn out to be a good solution for the classification of a true signal from other artifacts with high accuracy and reliability.

A deep learning framework for image reconstruction in photoacoustic tomography (PAT) is presented in [9]. A sparse data problem is discussed. A direct and highly efficient reconstruction algorithm based on a deep convolutional neural network was developed. Neural network weights are adjusted prior to the actual image reconstruction based on a set of training data. The proposed reconstruction approach can be interpreted as a network that uses the PAT filtered backprojection algorithm for the first layer, followed by the U-net architecture for the remaining layers. Numerical results demonstrate that the proposed deep learning approach reconstructs images with a quality comparable to the state-of-the-art iterative approaches for PAT.

In [10] the authors used an MLP (Multy Layer Perceptron) for the simultaneous determination of the laser beam spatial profile and relaxation time of the polyatomic molecules in gases in real time within trace atmosphere gas monitoring. The spatial profile of the laser beam is variable, so its simultaneous determination contributes to the precision of the photoacoustic experiment, because it will correct the resulting variations. The same authors go a step forward in [11], so a feedforward MLP recognizes both the spatial profile of the laser beam and the values of the laser fluence, which contribute to additional precision in the measurement of different pollutant concentration in a wide range of values in a urban and rural environment.

However, as far as we know, neural networks have not yet been applied to the recognition of the influence of processes that are happening inside the detector. Data used for characterization are dependent on those processes. This influence cannot be understood as noise, but as a systematic influence which depends on the detector, and two completely identical detectors do not exist in practice. Accordingly, detector recognition is a kind of measurement set calibration, particularly in situations of detector changes when higher gain or a different measurement range is needed for different materials and structures or because of the failure of the existing detector in the serial measurements of the same sample. Such a calibration is a necessary step for a further inverse problem solution, apropos the determination of the examined sample characteristics with an accuracy required for fundamental research, which is significantly higher than the accuracy required for the application of some materials and structures or for biomedical diagnostics. In this paper the methods are based on deep neural networks which are able to effectively and very quickly recognize detector influence so that the calibration of the used experimental set can be done as suggested.

III. MASSIVE DATASET REGRESSION MODELS FOR DETECTOR PARAMETER PREDICTION

Our aim is to incorporate computational intelligence, especially deep learning, in the so-called "intelligent measurement system", which will be able to perform complex commands. We expect that such a system will be able to learn and to adapt to specific problems and to maintain high accuracy, reliability, and measurement rate. In the beginning, our intelligent measurement system will have the possibility of signal autocorrection relative to instrument influence. Although the case study was done on gas-microphone photoacoustic frequency measurements, the method application can easily be extended to a great number of model-dependent measurement systems with variable detectors.

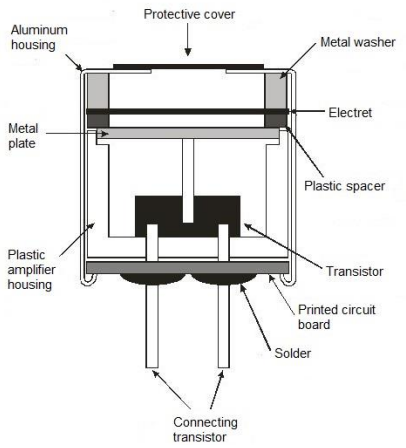

Fig.1. Schematic diagram of a cell of minimal volume.

We previously created a simple and cheap photoacoustic

measurement device [12], Fig.1. The common characteristic of of experimental signals due to the electronic or acoustic properties of the used instruments in the frequency domain [13], Fig.2. Based on the analysis of a great number of executed measurements on different materials and a comparison with the theoretical predictions which assume the detector to be ideal, it can be concluded that the microphone as the basic part of the detector measurement system brings most of the disturbances into the experiment.

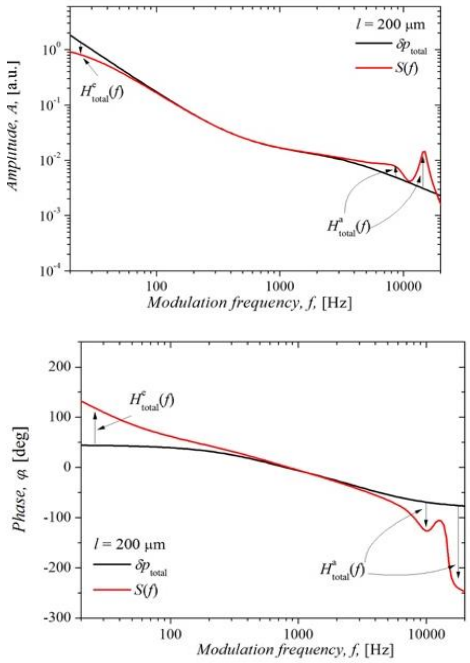

Fig. 2. Simulated a) amplitude and b) phase of the total photoacoustic signal (black line) and distorted experimental signal (red line)

A database of 67500 records was obtained from a well-known theoretical model. We obtained a massive dataset, and it is in precisely such datasets that deep learning recognizes interesting and useful structures, as well as patterns of non-linear dependence. The dataset was structured and labeled. The theoretical data corresponded to the commercial microphone ECM30B. Based on the statistical analysis of the collection of experimental measurements, it was concluded that frequency f_2 is the most stable one compared to the observed parameters, and three values were taken for network training: the central value 25 Hz and two values which are ± 5 % of the central value (23,75 Hz and 26,25 Hz). Also based on the statistical analysis, it was concluded that 10 values should be taken for each of the frequencies f_3 and f_4, distributed at equal distances in the range 8930-9866 Hz and 13965-15432 Hz, respectively. The least stable parameters are the damping factors of the second order low-pass filter, and they were presented with 15 values which were irregularly distributed from 0.015 to 0.99. Some of the curves from this dataset are presented in Fig. 3 (2250 lines). Every curve is presented with 200 points, and every point is presented with two characteristics, an amplitude and phase. In this way, one record in the database is presented with 400 all photoacoustic measurement systems is the high distortion features, 200 amplitudes and 200 phases. The dataset was first shuffled and then divided into a training set of a total of 57500 records or 82.6% of the total number of recordings, a validation set and a test set both of 5000 records or 8,7% of the total number of recordings. In this way, the training, validation and test sets were obtained randomly.

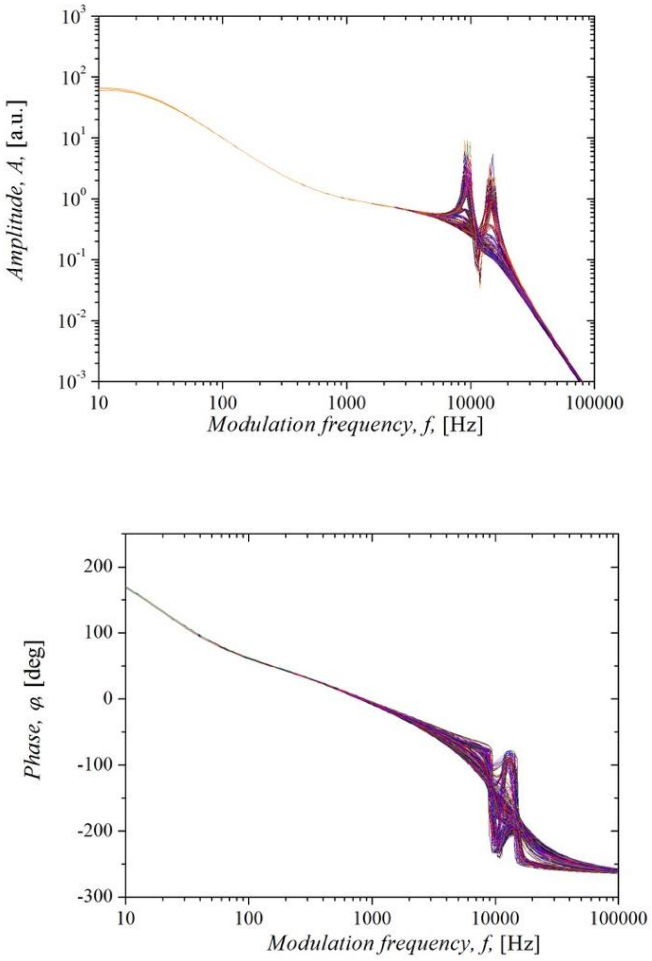

Fig.3. Curves: a) amplitude and b) phase of distorted photoacoustic signals with different microphone characteristics from the dataset used for network training [14].

Our aim is the development of a regression model for the prediction of five specific microphone parameters connected to its electronic and geometric features, which are not determined by the producers and could not be found in the specifications for the particular microphone. Based on our analysis of the theoretical models of the microphone as a sensor and a converter of pressure changes into an electrical signal, as well as those carried out on electrical measurements, it was shown that a five-parameter description of the detector influence on every detected signal is enough. In that way, microphone influence on the experimental signal can be determined. Now it is possible to correct the experimental signal in order to reach a “pure” signal, generated only from the excited sample. An MLP was our choice because of higher accuracy.

In this paper we present three regression models. The first model has an MLP with three layers, two of which are hidden, the first one with 30 neurons, and the other with 17 neurons, and one output layer with 5 neurons. The second model has 5 MLPs with three layers, two hidden, the first one with 30 neurons and the second with 17 neurons, and one output layer with 1 neuron. The third model has an ANN (Artificial Neural Network) with one hidden layer with 47 neurons, and is a shallow neural network. The network outputs represent the targeted microphone parameters: f_2, the characteristic microphone frequency connected to its RC characteristics, f_3, f_4 characteristic acoustic resonances of the microphone, and ξ_3 and ξ_4 reciprocal quality factors. The characteristics of a lock-in amplifier, whose role is played by the sound card described with parameter f_1, is considered known (f_1=15Hz). The input vector has 400 features, Fig. 4

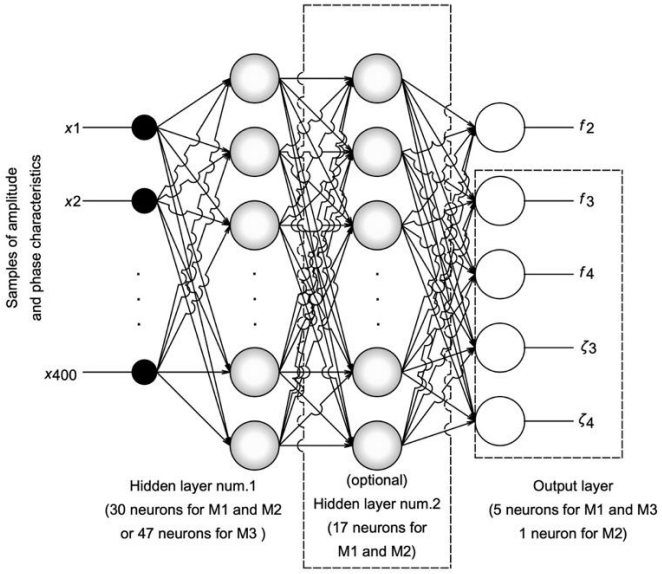

Fig. 4. Structure of Model1, Model2 and Model3

The normalization of the input vector was achieved by dividing each element x_i of the input vector by the maximum absolute value, determined over all the examples at the "i" frequency. This normalization type proved itself as the best solution for our model, then some others. With the application of this normalization type and without a value change in the other parameters, an acceptable value for the accuracy of the model was obtained in the iterative process of model parameter selection. We tested two more types of normalization, normalization obtained by subtracting the mean value of all examples at the "i" frequency from each element x_i and by dividing it by a standard deviation, as well as N2 or the Frobenius norm, but the results were not acceptable. The output vector y is normalized in a similar manner.

We chose a tanh activation function and the Xavier algorithm for weight initialization. [15]

We applied supervised learning for the model training. The Adam algorithm for error function evaluation was applied in order to achieve optimal weight values in the backprop [16]. The optimization is intensified by the Mini-batch technique, which is applied when the dataset is big enough (as it is in this case). This technique provides visible results of parameter optimization even in the first epoch, thanks to the division of the given dataset into smaller ones, which are treated as a whole, and applies error function evaluation on these smaller datasets. The learning rate for all the models has the same value of 10^{-4}.

The open source platform for machine learning, Tensorflow, was used for the realization of the models. Tensorflow is very popular for the realization of deep neural networks. It is based on a data flow graph. The graph nodes represent mathematical operations, while the graph edges represent the multidimensional data arrays (tensors) that flow between them.

Metrics for the models were defined, the same for all three models: deviation from the accurate value is less or equal to 5%, and that corresponds to the photoacoustic experiment. Model accuracy was analyzed relative to the set metric. The error function value on the training set and the validation set are similar, so we can conclude that model generalizes well and is not overfitted.

In accordance with Table1, it was concluded that the best results were achieved with Model 2, and the worst with Model 3. By dividing the same number of neurons into two layers, we got an accuracy approximately 2% higher in Model 1 than in Model 3. This difference will be bigger if the network is trained on experimental values, because theoretical models present idealizations, i.e. an approximation of real conditions. Is 2% small enough not to make a difference between the models? It depends on the application, for the photoacoustic experiment for industrial application it is significantly high. The importance of neural network depth for learning was proven by the increase of the accuracy of the model with more layers, under the same conditions (learning rate, number of epochs). Model 2 proves the fact that the deeper the neural network is, the better the recognition of behavior patterns in the data. Reducing the deviation from the accurate values in Model 2 in relation to Model 1 shows that the multilayer neural network can approximate the nonlinear output quite well. In Model 2 the neural network concentrates all its power on one output and achieves a very high accuracy for 3 of the 5 microphone parameters, as much as 99.99%, while training lasts for a far smaller number of epochs.

TABLE I:
A COMPARATIVE ANALYSIS OF THREE REGRESSION MODELS FOR THE PREDICTION OF THE MICROPHONE PARAMETER

	Accuracy		Cost		Numbers of epochs
Model 1	98.59%		0.000001		5000
Model 2	99.99%,99.99%,99.99%,99.61%, 99.596%		<0.000001,<0.000001,<0.000001,0.000001, 0.000001		1500,1500,1500,3000,3000
Model 3	0.969833		0.000003		5000
Average deviation from the accurate value expressed in the percentage of the accurate value on the training set					
Parameter	f_2	f_3	f_4	ξ_3	ξ_4
Model 1	0.02025029	0.08571574	0.03485037	1.0117933	0.59135133
Model 2	0.00367374	0.04975093	0.02321718	0.44225055	0.28317332
Model 3	0.03180477	0.1299281	0.06766562	1.9676312	1.1875261
Average deviation from the accurate value expressed in the percentage of the accurate value on the validation set					
Parameter	f_2	f_3	f_4	ξ_3	ξ_4
Model 1	0.02028082	0.08540299	0.03530468	0.998583	0.60733956
Model 2	0.00359443	0.05007159	0.02289878	0.4521597	0.31682032
Model 3	0.03162626	0.12913962	0.06732392	1.9448547	1.1696345
Average deviation from the accurate value expressed in the percentage of the accurate value on the test set					
Parameter	f_2	f_3	f_4	ξ_3	ξ_4
Model 1	0.02026834	0.0861348	0.0351213	0.9855594	0.5777709
Model 2	0.0037558	0.04898341	0.02315352	0.45252872	0.2967481
Model 3	0.03270168	0.13082047	0.06930758	1.9330658	1.2145972
Prediction time					
	CPU time		Computation_time(CPU +load time)		
Model 1	14 ms		31 ms		
Model 2	14 ms		5x30 ms		
Model 3	12ms		29ms		

In Model 1 the neural network splits its power to the five outputs, so the accuracy of this model is smaller. The same MLPs in Model 2 for different microphone parameters achieve different accuracies. This difference is just more proof that the network approximates the real situation very well. Parameters $\xi_3\, i\, \xi_4$ are very unstable photoacoustic quantities which depend on many other parameters. The theoretical model is not able to approximate the parameters very well. The neural network discovered this instability in the data.

IV. Conclusion

In this paper we discussed deep learning application in the calibration of model-dependent measurement techniques with nonlinear detector influence on the measured signal. Few examples of successful application were presented. The analysis of three regression models for microphone parameter predictions in photoacoustic experiments was presented. It was shown that higher accuracy was achieved by models with two hidden layer neural networks compared to a model with one hidden layer neural network, for the same total number of neurons. Based on this, it can be concluded that it is the depth, not the size of the neural network that matters. In the development of the regression model for the purpose of correcting the measuring chain influence in photoacoustic experiments, we selected a two hidden layer neural network structure, not one with more hidden layers, because the achieved accuracy was satisfactorily high. We accomplished the set metric. However, we intuitively know that models with a higher depth will be our actual research direction for some of future applications in model-dependent measurements, especially for the case of complex nonlinear dependences of input and output quantities.

For the purpose of a "smart" measurement system development, we chose Model 1 as the most practical solution for our needs. The application of this regression model for calibration of experimental set could be generalized on similar problems in other measurement or transmission problems. We consider Model 1 and Model 2 as the real choices relative to the given requirements.

ACKNOWLEDGEMENTS

We would like to thank to Ministry of Education, Science, and Technological Development of the Republic of Serbia for the financial support for this research through Project Nos. III45005. Special thanks also to college Drasko Furundjic, Institute Mihailo Pupin, for practical suggestions during the research.

Player Skill Modeling and Feature Selection for a Video Game

Zoran Ž. Ćirović and Nataša A. Ćirović

***Abstract*—E-sports has increased significance, with growing number of professional players and monetization potential, thus the player skill modeling in strategy games has long been a subject of interest for researchers. In this paper we use publicly available video game telemetry data from StarCraft 2 to explore the player skill modeling and development of expertise. The analysis includes selection of statistical features for original dataset and their application to a classifier. The statistical features are obtained from the original data, applying statistical functions: mean, standard deviation, minimum, maximum, inter-quartile range, skewness, kurtosis. On such obtained set of statistical features, we applied feature ranking using t-test hypothesis, then feature subset selection is done using suboptimal searching techniques. We tested the obtained results on standard *k*-NN classifier.**

***Index Terms*—Video game skill learning; Feature selection; Feature ranking; *k*-NN classifier**

I. Introduction

HAVING in mind the enormous popularity of e-sports today, and that these skills must be acquired by practice, the significance of prediction of parameters that can establish the level of acquired skills is clearly of great importance for the gain in interaction with players. Additionally, e-sports is already generating significant revenues and the potential of further monetization in the next few years can reach up to $3 billion, [1].

Thus, the significance of player modeling, expression of human characteristics and prediction that can establish the level of acquired skills is clearly of great importance for the gain in interaction, [1], [2].

In real-time strategy (RTS) games the players do not play in turns, thus motor skills with a keyboard and mouse are an integral component of the game. One such game is StarCraft 2, that supports semi-professional and professional players, that often have a decade or more of RTS experience, [3].

Furthermore, it is reasonable to expect that the development of skill learning expertise would resemble the development of expertise in less related domains, such as education (e.g. VR surgery skills training, [4]) or health (e.g. personalizing games for rehabilitation of patients [2]).

Great popularity, as well as profitability, of gaming yields the increased research of the player modeling, [2], [5]. Some of the research directions belong to the cognitive science [4], [6]. Others are in the domain of machine learning, for e.g. Ravari et al. compare the relative importance of match and player skill and style features for the purpose of winner prediction [7], and Avontuur et al. deal with determining the player's league as early in the game as possible, [8].

Chen et al. [9] researched classification applying various clustering techniques and dimension reduction, over the dataset in [4].

With the increased amount of information available today, the problem of handling big datasets appears. Reducing the number of dimensions in an adequate way has become extremely important. This is done by using feature selection techniques, [10], [11]. In order to choose a good feature set, we require a way of measuring the ability of a feature set to discriminate accurately between two or more classes.

In our research we use the video game telemetry data from StarCraft 2 from the publicly available dataset collected by Thompson et al. [4].

The goal of our research is to determine the features that best describe the skill levels, for modeling player of StarCraft 2, using the dataset from [4]. Having in mind previous research, we applied a new process of feature selection by combining ranking and searching algorithms. Such hybrid technique of feature selection can include many statistical functions for feature extraction, considers the nature of the features and it can be implemented to similar applications, e.g. skill acquirement. We tested it with the standard *k*-NN model and gained significant accuracy for relatively small number of features.

II. Data Processing

Data processing block diagram is shown in Figure 1. Input vectors are first collected, then in the preprocessing part, transformed into feature vectors that are more suitable for further processing.

Next, feature selection is performed. The last part of processing is the classifier, where the selected features are used in two separate phases: (i) in the training phase – for modeling activities, and (ii) in the testing phase. If the dataset is not big enough, then the procedure of cross validation is applied.

Nataša A. Ćirović is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar Kralja Aleksandra, 11000 Belgrade, Serbia (e-mail: natasa@etf.bg.ac.rs).

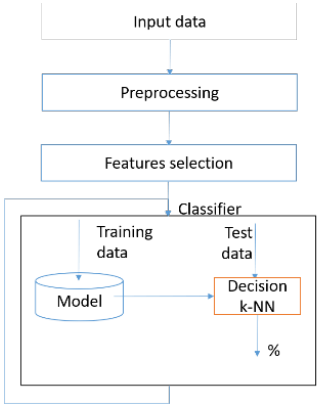

Fig. 1. Data processing block diagram.

A. *Preprocessing*

Data preprocessing block diagram is shown in Figure 2. In order to achieve equal contribution of all features in classification, normalization of input vectors should be implemented [13]. If the expected feature distribution is standard Gaussian, and the variance is not too small, standardization should be implemented instead [14].

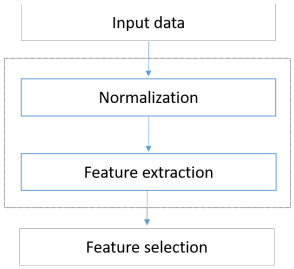

Fig. 2. Block diagram of preprocessing.

If statistical data is formed in the preprocessing phase, then framing of input vectors is performed. Framing is grouping of vectors in order to obtain statistical feature vectors. In framing overlapping is mandatory, in order to include the sudden changes in data.

B. *Statistical features*

A collection of statistical functions used for creation of statistical features is shown in Table I [15], [16]. A more precise definition of some of the features is given by (1) to (3).

TABLE I
SET OF ANALYZED FEATURES

	Description
Avg	Mean value
Std	Standard deviation
max	Maximum value
min	Minimum value
iqr	Interquartile Range
SK	Skewness
K	Kurtosis

$$iqr = Q_3 - Q_1, \tag{1}$$

$$SK = \frac{n}{(n-1)(n-2)} \sum \left(\frac{x_i - Avg}{Std} \right)^3, \tag{2}$$

$$K = \frac{n(n+1)\sum (x_i - Avg)^4 - 3\left(\sum (x_i - Avg)^2\right)^2 (n-1)}{(n-1)(n-2)(n-3)\,Std^4}, \tag{3}$$

where Q_1 and Q_3 are mean values of the first and last quartile, respectfully.

III. FEATURE SELECTION

Feature selection reduces the dimensionality of feature space, removes redundant, irrelevant or noisy data. Some of the benefits for the applications are: (i) model simplification; (ii) more efficient use of the model, both in long-term training and in testing or exploitation phase; (iii) generalization of features is emphasized, increasing robustness and reducing the influence of excessive overfitting, [10]-[12]

The straightforward algorithm is to test all possible subsets of features thus determining the one that gives the best results for the classifier. This is the process of complete search and it is not feasible in the process of calculation and it is can be specific to the used classifier. The alternative is to use a combination of some feature selection techniques, i.e. determining a subset of the complete set of features by applying a metric that defines the quality of the selected subset.

There are several classifications of feature selection methods. Based on the number of variables considered:

- Univariate methods, variable ranking - consider the input variables one by one;
- Multivariate methods, variable subset selection - consider entire groups of variables jointly (e.g. greedy search algorithms).

Based on the usage of the classification model in the feature selection process:

- Filter: evaluate quality of selected features, independent from the classification algorithm that will use them;
- Wrapper: require application of a classifier (which should be trained on a given feature subset) to evaluate this quality;
- Embedded methods: the feature selection method is built in the model (or rather its training algorithm) itself (e.g. decision trees).

A. *Feature selection based on ranking methods*

Feature selection based on ranking methods can be used as a method for individual independent features selection. Thus, certain criterion is used. By ranking we can determine the significance of individual features, but not the significance of a subset of features. Some of the criterion that can be used for ranking are:

- T-test – Absolute value two-sample t-test with pooled

variance estimate;
- Entropy – Relative entropy, also known as Kullback-Leibler distance or divergence;
- Bhattacharyya – Minimum attainable classification error or Chernoff bound.

B. *Sequential feature selection search*

Sequential feature selection search algorithms are a family of greedy search algorithms, which are of multivariate type.

Some of the methods are:
- Sequential Forward Selection;
- Sequential Backward Selection;
- Sequential Floating Forward Selection;
- Sequential Floating Backward Selection.

The methods are iterative, and in each step, the best feature is selected, based on the applied criterion. The process is repeated as many times as the number of features we want to select or get appropriate accuracy.

IV. Dataset

For obtaining the experimental results the dataset was collected by Thompson et al. [4], from 3,340 players of RTS video game - StarCraft 2, across 7 distinct levels of skill called leagues (Bronze, Silver, Gold, Platinum, Diamond, Masters, Professional). Every record contains 18 different features. The data is gathered by remote measurement without affecting the players in any way. Besides the first two inputs in the record that are used for identification (GameID and LegueIndex), the features are [4]:

Age: Age of each player (integer);

2. HoursPerWeek: Reported hours spent playing per week (integer);

3. TotalHours: Reported total hours spent playing (integer);

4. APM: Action per minute (continuous);

5. SelectByHotkeys: Number of unit or building selections made using hotkeys per timestamp (continuous);

6. AssignToHotkeys: Number of units or buildings assigned to hotkeys per timestamp (continuous);

7. UniqueHotkeys: Number of unique hotkeys used per timestamp (continuous);

8. MinimapAttacks: Number of attack actions on minimap per timestamp (continuous);

9. MinimapRightClicks: number of right-clicks on minimap per timestamp (continuous);

10. NumberOfPACs: Number of PACs per timestamp (continuous);

11. GapBetweenPACs: Mean duration in milliseconds between PACs (continuous);

12. ActionLatency: Mean latency from the onset of a PACs to their first action in milliseconds (continuous);

13. ActionsInPAC: Mean number of actions within each PAC (continuous);

14. TotalMapExplored: The number of 24x24 game coordinate grids viewed by the player per timestamp (continuous);

15. WorkersMade: Number of SCVs, drones, and probes trained per timestamp (continuous)

16. UniqueUnitsMade: Unique unites made per timestamp (continuous);

17. ComplexUnitsMade: Number of ghosts, infestors, and high templars trained per timestamp (continuous);

18. ComplexAbilitiesUsed: Abilities requiring specific targeting instructions used per timestamp (continuous).

Here PAC stands for Perception Action Cycle. Think of a PAC as when a player moves the camera and takes at least one action. Within a PAC there is a calculated number of actions, latency time between those actions, and gap of time between the next PAC.

V. Experimental Results

For examining if the selected subset of features is suitable, we use the standard *k*-NN classifier. For normalization of the input data we use minmax scaling function.

A. *Experiment 1*

Firstly, we created a *k*-NN classifier, using the 18 original input features, after normalization, from the dataset. The achieved error was 33.96%. The used classifier is defined for $k = 3$, where k is the number of nearest neighbors. For other values of k the results did not vary significantly (around 1%). The model is tested on different samples then the once used for training, using cross validation with 5 folds. Even though the number of features is small, we tried to throw out less significant features and got a gain of only 3.33%, i.e. the error is 30.63%.

B. *Experiment 2*

Statistical data processing is realized by grouping normalized input data in frames of length 30, with overlapping between frames. We used statistical functions shown in Table I for creation of statistical features. Thus, we got total of $18 \cdot 7 = 126$ statistical features. Next, we investigated 7 statistical groups separately, and all together, using the same classifier. The error rates are shown in Fig. 3.

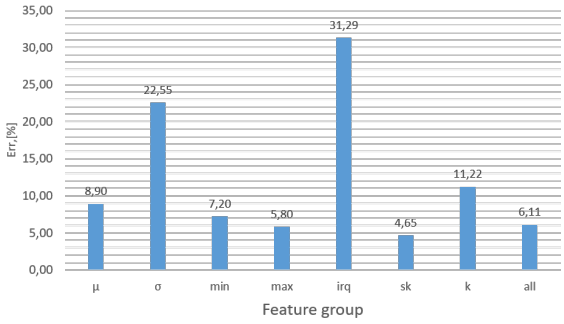

Fig. 3. Error rates for statistical features groups.

C. *Experiment 3*

Next, the analysis of feature significance for each skill level was done with T-test as the ranking criterion. Fig. 4 and fig. 5 show the 40 best ranked features for input variables, for skill levels 2 and 6, respectfully.

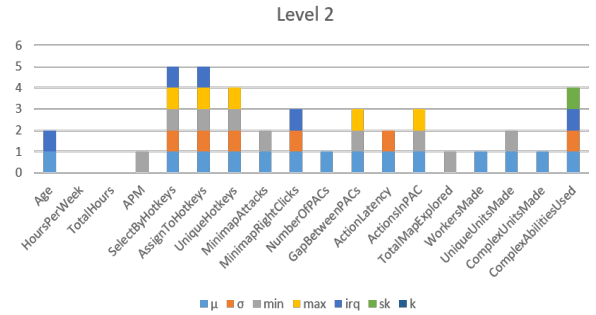

Fig. 4. Best 40 features for Level 2, for input variables.

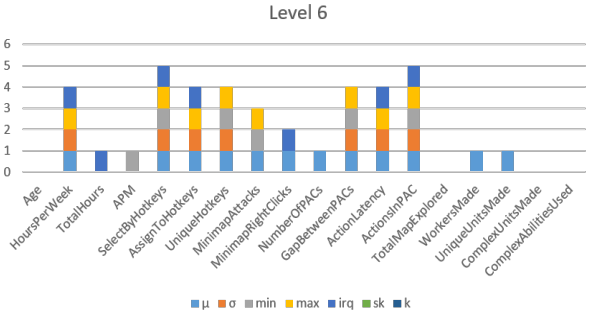

Fig. 5. Best 40 features for Level 6, for input variables.

The obtained results provide an individual ranking for each feature. For example, the Age feature is important for the starting level, but it is totally insignificant for higher levels. On the contrary, the feature SelectByHotkeys is highly ranked for all levels.

Fig. 6 and fig. 7 show the 40 best ranked features for statistical functions, for skill levels 2 and 6, respectfully.

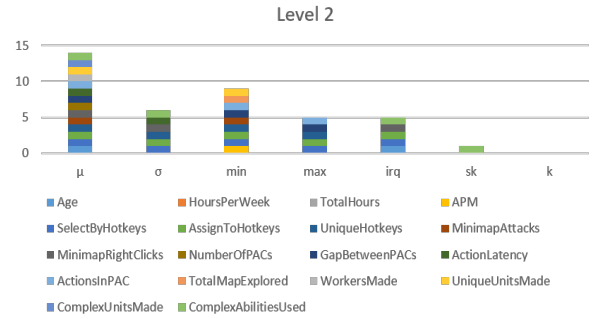

Fig. 6. Best 40 features for Level 2, for statistical functions.

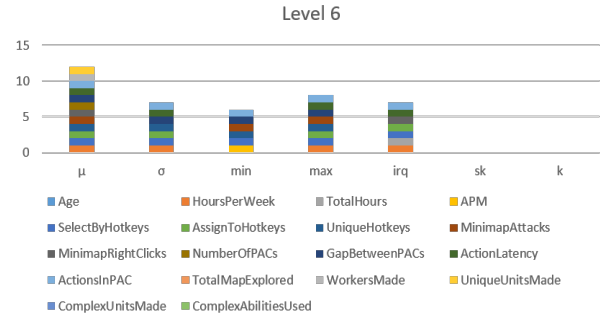

Fig. 7. Best 40 features for Level 6, for statistical functions.

We can observe that the group of features based on irq, skewness and kurtosis show different significance, depending on other features involved in the entire feature vector and skill levels.

Obviously, in this way it is not possible to define a unique group of features for all skill levels. For this reason, we investigated joint set of selected features for all skill levels in the next experiment.

D. *Experiment 4*

For every skill level we chose smaller number of best ranked features, *M*. Final feature set is a union of selected features for each level, *N*. Results for different *M* are shown in Table II. By implementing feature selection for all skill levels, we gain higher accuracy.

TABLE II
ERROR OF CLASSIFICATION FOR BEST *N* FEATURES

M	3	5	7	10	15
N	17	19	23	36	47
Err, [%]	2.58	2.42	4.03	4.03	3.89

E. *Experiment 5*

Last experiment is refining the selection of features obtained in the previous experiment. Using Sequential Forward Selection SFS for $M = 15$, ($N = 47$), we choose the best subset of 17 features. The error rate in this case is 2,03%.

The selected features are:

- Mean: 1) APM: Action per minute; 2) SelectByHotkeys; 3) AssignToHotkeys; 4) UniqueHotkeys; 5) GapBetweenPACs; 6) ActionLatency;
- Std. dev.: 7) Age 8) SelectByHotkeys; 9) GapBetweenPACs;
- Min.: 10) HoursPerWeek 11) SelectByHotkeys; 12) AssignToHotkeys; 13) UniqueHotkeys; 14) MinimapAttacks;
- Max.: 15) MinimapAttacks; 16) NumberOfPACs; 17) ActionLatency.

VI. CONCLUSION

We investigated input variables gathered from players of one RTS game, with the aim to determine the characteristics of players that can best describe their skill level. We compared the experimental results to the initial experiment implemented using the standard *k*-NN classifier for $k = 3$, on the original dataset. The achieved error in this case was 33.96%.

We implemented the statistical processing of the input variables with 7 statistical functions, thus we got statistical features. Based on this, we considered classification on 7 groups of statistical features, and all together. The statistical extraction provided gain in accuracy, with the error rate going from 4.65% to 31.29% for individual groups, and 6.11% for all features together. The obtained results show the significance of the statistical feature extraction in this case.

Using the feature selection ranking method, we selected the

best features for each level. The obtained results provide an individual ranking for each feature. Results show different significance for different groups of features, Fig. 4-7. In this way it is not possible to define a unique group of features for all skill levels.

In order to determine the significant features for all skill levels, we created a union of previously selected 15 best features of each level, obtaining the set of 47 different features. On this set we implemented the greedy search algorithms to obtain the subset of 17 best features. On this subset the *k*-NN classifier provides the error rate of 2.03%. We can observe that among the best 17 features there are no features from all statistical groups.

By combining selection methods of ranking and greedy search we can get significant improvements in classification of skill levels.

With the obtained feature subset, we can determine the skill level of the player with accuracy of approx. 98%.

The procedure of feature selection is efficient, considers the nature of the features and it can be implemented to similar applications, e.g. skill acquirement.

In future work we plan to verify our results with other classifiers. Also, we plan to do a comparative analysis using other feature selection techniques.

Semantic Technology-Based Platform for Automated Assessment of Information Systems Course Projects

Nenad Petrovic, Milorad Tosic and Valentina Nejkovic

***Abstract*— When it comes to computer science education, it has been recognized that practical programming assignments (projects and exercises) are essential element. However, in recent years, the number of students enrolled to bachelor degree computer science and information technology courses has increased dramatically, bringing new challenges for universities and educational institutions. Many problems in courses with huge number of participants are related to the quality of student assignment/exercise evaluation, as it is time-consuming and error-prone process. Therefore, the automation of student assignment evaluation is seen as a solution. While there are many existing tools and platforms that tackle this problem, most of them are limited only to exercises for introductory courses. In this paper, we focus on aspects of automated assessment of student projects based on Java and MySQL, developed in context of the third year bachelor degree Information Systems course at Faculty of Electronic Engineering, University of Nis in Sebia. As an outcome of this research, we propose the platform architecture based on semantic technology and present a tool for automated project assessment based on static code analysis aiming the usage in blended learning environments.**

***Index Terms*—education; semantic technology; static code analysis**

I. Introduction

Assessment is of utmost importance for educational activities, as it provides feedback whether the goals of education are achieved or not to both the students and teachers.

Continuous assessment during a course can be highly beneficial, as it can directly enhance the learning process by providing early feedback on the quality of students' exercise solutions [1, 2, 3]. However, providing timely feedback on student programming exercises and helping them think about the mistakes they made is time-consuming and requires huge effort, especially when it comes to classes with large number of students, as it is the case nowadays at universities where computer science and information technology courses are taught. In recent years, we have witnessed a huge growth of number of computer science and information technology university students worldwide. Exactly the same trend is notable locally in Serbia as well, reflecting the global trends [4]. As the class size grows, the amount of work related to assessment is often limited in some way, which may affect the evaluation quality. Therefore, the automation of assessment process is seen as a possible solution [3]. Automatic assessment tools not only speed-up the evaluation process, but could also improve the quality and fairness of the assessment.

In past, most platforms for automatic programming exercise assessment were based on the externally observable behavior of the code, treating it as a black box. While this approach might be acceptable for exercises in introductory-level courses where the correct output for particular test inputs is known in advance, it is not suitable for more complex student projects where there might be countless possibilities of the outputs which still might be considered valid and positively evaluated. This is the case in courses where the assignments have more open formulation that leaves a certain degree of freedom and creativity to students, such as Software Engineering, Information Systems and Web Programming. In assignments for these courses, it is often required that students implement some business logic aspects that could require in-depth semantic analysis of the code meaning if assessed automatically, rather than simple comparison to pre-defined correct outputs for given inputs. Moreover, most of the existing automatic assessment platforms are often limited to one programming language, while the projects in previously mentioned courses might involve usage of many tools, programming languages and technologies.

In this paper, we focus on automated assessment of Information Systems course students' projects on third year of bachelor degree (Faculty of Electronic Engineering, University of Nis, Serbia) that are based on Java and MySQL. As an outcome, we propose a semantic framework, platform architecture and present a case study where our tool prototype for static semantic code analysis (process of examining source code without the execution) is used to confirm the effectiveness of the proposed approach in blended learning environment.

II. Related work

There are many existing solutions for automatic assessment of student's Java program code. Some of them rely only on the results obtained during the execution of pre-defined tests, the others only take into account the static code analysis, while there are also solutions that involve both the dynamic

Nenad Petrovic, Milorad Tosic and Valentina Nejkovic are with the Faculty of Electronic Engineering, University of Niš, Aleksandra Medvedeva 14, 18000 Niš, Serbia (e-mail: nenad.petrovic@elfak.ni.ac.rs, milorad.tosic@elfak.ni.ac.rs, valentina.nejkovic@elfak.ni.ac.rs).

and static aspects, which is the case in more recent works. However, it is identified that the most of these solutions are targeting introductory computer science courses (Algorithms and Programming, Data Structures, Programming Languages, Object-oriented Programming) where student project structure is quite simple. Moreover, most of these are mainly designed to be integrated with MOOCs, where the project assessment is solely based on the automatic assessment, while we aim to provide a solution that will support the educational process in blended learning environment where the final assessment would still involve teacher at certain points. Despite the fact that MOOC platforms have achieved great success around the world, especially for low-cost corporate training and certification, when it comes to the teaching practice in universities, this model does not necessarily have good results [5]. Blended learning and flipped classroom learning techniques that combine online resources and technology in various ways with personal engagement between faculty and students have shown much better outcome [4]. In what follows, some of the existing solutions for automated students' programming exercise assessment will be mentioned.

In [6] and [7], grading systems for Java introductory programming courses was presented that grades submissions both dynamically (based on JUnit framework) and statically (based on graph representation of the program and quality measured by software metrics). These solutions performed well, but they are limited to basic procedural programming exercises. In [3], a similar approach was used, providing more sophisticated feedback. The solution for static analysis of students' Java programs presented in [8] is based on software engineering metrics and structural similarity. However, that framework does not implement semantic analysis and is still limited to introductory exercises. Moreover, the framework presented in [9] offers libraries for both the static and dynamic Java program assessment and it copes well with object-oriented programming exercises, but still does not cover the assessment of the assignments that have more complex structure and involve the usage of many different tools and technologies. On the other side, the approach shown in [2] is based model-based black-box testing to assess both the functional correctness and algorithmic complexity of students' exercises in the introductory-level programming courses.

The main advantage of our solution, compared to previously mentioned work is the ability to perform in-depth semantic analysis of students' program code based on semantic code annotations in order to detect program properties and support for courses with projects that have more complex structure (not limited only to introductory-level courses) that might involve the usage of many different programming languages, tools and technologies.

The idea of the adopted approach originates from [10, 11], where parsing and semantic code annotation were used for design-time analysis of robotic experiments written in a domain-specific language. For parser development, Xtext[1] framework was used. It enables the generation of corresponding parser using a simple, but powerful grammar definition language.

[1] https://www.eclipse.org/Xtext/

III. Semantic Framework

Semantic analysis of digital artifacts is a process of understanding their meaning based on context. In cases when applied to program code, it is required both to parse it and store the knowledge extracted from the code in suitable way, so the reasoning mechanisms can be applied to infer knowledge from the existing facts, while traditional databases just enumerate all available facts.

For this purpose, we use ontologies. An ontology is an explicit and formal description of knowledge about a domain of interest, the core of which is a machine-processable specification with a formally defined meaning [12]. Resource Description Framework (RDF) is a formal language for specification of structured information that is often used to formally describe ontologies [12, 13]. It is a data model that provides a way to express simple statements about resources, using named properties and values [12, 13]. In context of RDF, classes are used to define types of things and categories. In addition to defining the classes of things within the ontology, it is also possible to define specific properties that characterize those classes of things. Relations and facts about the classes, their properties and relations are stored as triplets within the RDF triple store for both the ontology definition and its instances. SPARQL is a semantic query language that provides possibility to retrieve and manipulate the data stored within the RDF triple store [12, 13].

Within our framework, the ontologies are used to represent the knowledge about various aspects about both the static and dynamic properties of student projects. Static properties of the project refer to the presence of the necessary project artifacts and their meaning in project context. On the other side, the dynamic properties are related to the behavior of the application during the execution. In Fig. 1, an overview of the ontologies behind our framework is given.

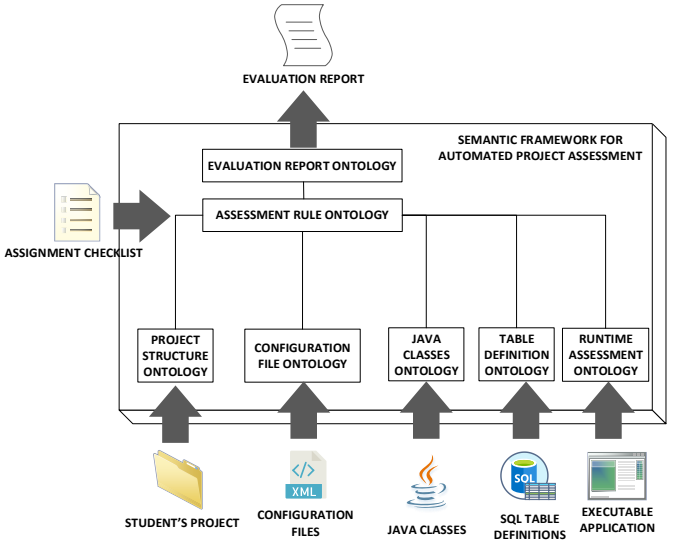

Fig. 1. Ontologies behind the semantic framework for automated assessment of student projects

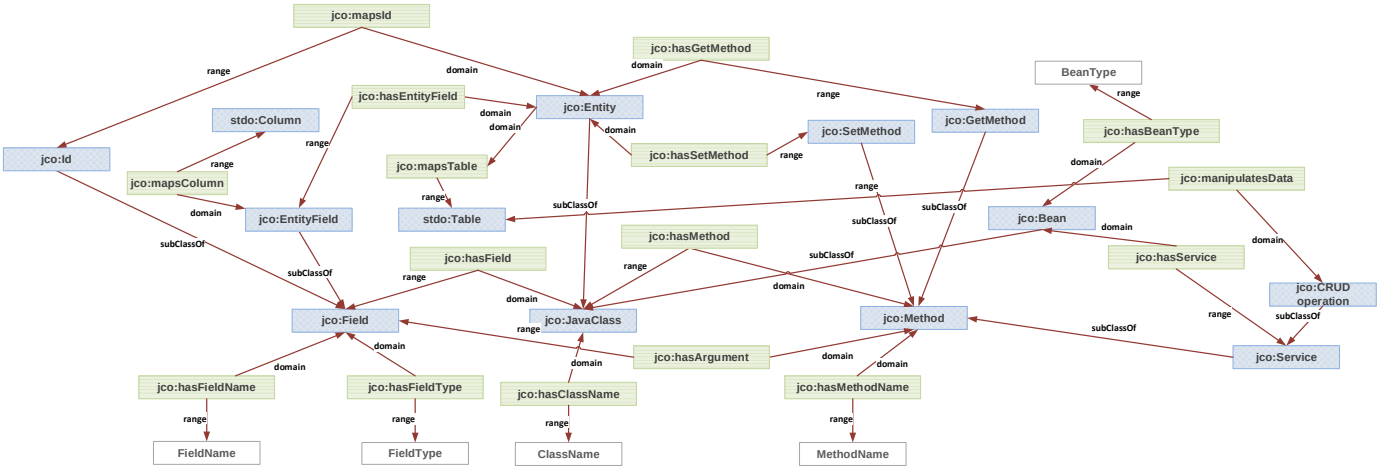

Fig. 2. An excerpt from the Java Classes Ontology that is used for static code analysis

Project Structure Ontology represents the knowledge about the structure of student's project and which are the assets that need to be contained within the project. In scope of this framework, we focus on Java EE Maven projects that are using Hibernate for object persistence and Enterprise Java Beans for business logic. Configuration File Ontology is used to store the knowledge about the structure of specific configuration files, such as pom.xml for Maven projects and persistence.xml. Java Classes Ontology describes the structure of various types of Java classes, such as Entity classes used for JPA/Hibernate ORM mapping and EJB for business logic implementation. For example, Entity classes are used for object persistence and must map to a valid database table and corresponding columns, identifier and contain getter/setter methods. This way, we provide the means for static, semantical Java code analysis based on pre-defined queries in order to detect whether certain conditions are satisfied within the student's code. In Fig. 2, an excerpt from the Java Classes Ontology is given. Table Definition Ontology holds the knowledge about the representation of SQL data definition statements that are used for creation of the database that is a part of the project. While all the previously mentioned ontologies refer to the static aspects of project assessment, Runtime Assessment Ontology should contain the knowledge about the application behavior obtained during the execution, based on pre-defined tests. Moreover, the Assessment Rule Ontology (depicted in Fig. 3) represents the course instructor-defined evaluation criteria for both the static and dynamic project aspects used for assessment.

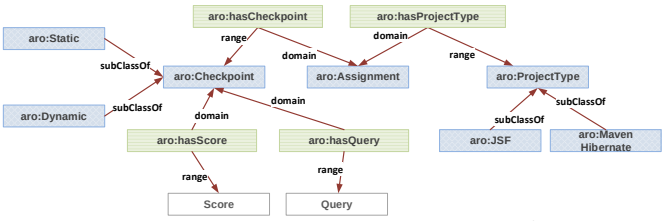

Fig. 3. Assessment Rule Ontology holding the teacher-defined evaluation criteria

These evaluation rules are defined as a list of checkpoints that project needs to satisfy. Each checkpoint has its score value and the corresponding assert written as a SPARQL query that needs to be executed against the RDF triple store to determine whether the considered student project satisfies the given criterion either static or dynamic. Additionally, the information about the project type can be used in order to check if a particular project complies with the required structure requirements and contains all the necessary elements for the specific project type (Java Web Application, Maven Hibernate etc.). An example SPARQL query for a checkpoint that determines whether the Java entity class correctly maps the table name and identifier to SQL table, for an assignment that involves object-relational mapping, is given in Listing 1.

```
PREFIX stdo: <http://www.tasorone.com/tsc/resources/stdo/>
PREFIX jco: <http://www.tasorone.com/tsc/resources/jco/>
SELECT ?entity ?table
WHERE {
  GRAPH <http://www.example.com/project1> {
   ?entity jco:mapsId ?id.?table stdo:hasIdentifier ?id.
    ?entity jco:mapsTable ?table_name.?table stdo:hasName
?table_name.
  }
}
```

Listing 1. An example SPARQL query for a checkpoint in assignment that involves object-relational mapping

Finally, the Evaluation Report Ontology stores the knowledge necessary to generate the assessment feedback, such as the list of checkpoints that are satisfied/not satisfied within the student's project and achieved scores for each of them.

IV. Assessment Platform Overview

In this section, the complete overview of the platform for automated assessment of student projects (illustrated in Fig. 4) is given, its main components are described and underlying mechanisms explained.

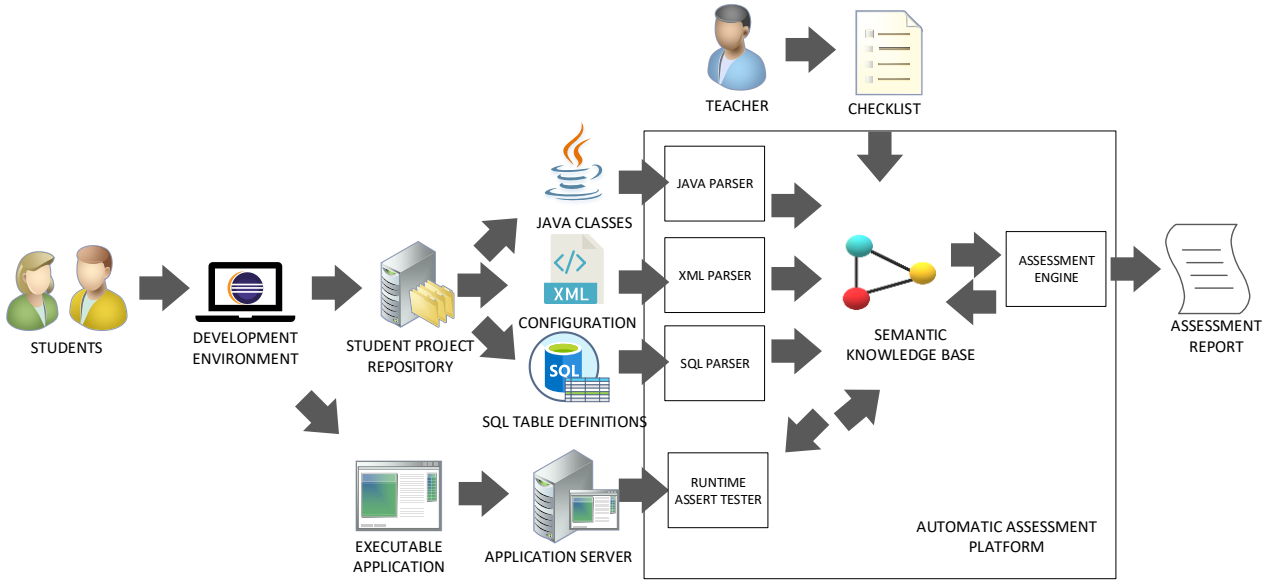

Fig. 4. Overview of the platform for automated student project assessment

The students develop the project artifacts using an integrated development environment (such as Eclipse) and, optionally, some additional tools (DBMS, Web/database server) depending on the concrete course requirements. The

projects with all the related artifacts are stored in remote student project repository (SVN, for example) that is synchronized with the student's development environment. Once the student decides to submit the assignment, the automated assessment process starts.

First, all the project artifacts that represent a source code (Java classes, XML configuration files, SQL table definitions) are recognized within the project directory and parsed using the corresponding parser. For each of them, during the parse tree traversal, the information of interest is extracted and stored within the semantic knowledge base, so it can be later used by the reasoning mechanisms for project assessment. This way, the static assessment of student project source code is performed. On the other side, the executable artifacts of the project are transferred to the application server that is able to run them. The execution is performed according to the pre-defined tests and led by the runtime assert tester component that inserts the triplets about the runtime application behavior to the knowledge base.

The project assessment (both static and dynamic) is performed according to the checklist defined by the course teacher. It consists of checkpoints that represent the conditions that both the source code and executable project artifacts need to satisfy, while each of them affects the final project score at certain percentage.

The final project score is calculated by the assessment engine. The assessment engine executes the queries corresponding to the assessment checkpoints and sums up the score obtained for each of them. Moreover, the corresponding triplet about the checkpoint assessment is inserted in triple store. The score calculation algorithm is given as simplified Java-alike code in Listing 2. Once the final score assessment is done, the results are showed as an assessment report which contains the scores for each of the checkpoints, so the students can be aware of their mistakes and improve their work for next submission or further assignments.

```
int assessment(String student_id,String assignment_name){
Checkpoint[] checkpoints=getAllCheckpoints(assignment_name);
int total_score=0;
foreach(Checkpoint checkpoint in checkpoints)
{
  int current_cpoint_score=0;
  boolean condition_satisfied=executeQuery(checkpoint.query);
  if(condition_satisfied)
  {
     total_score=total_score+checkpoint.score;
     current_checkpoint_score=checkpoint.score;
  }
insertTriplet(checkpoint,"isAssessed",current_cpoint_score);
}
insertTriplet(student_id,"hasAchieved",total_score);
return total_score;
}
```

Listing 2. Automatic project assessment algorithm

V. Case Study

As a case study, we consider automated assessment of student assignments developed as an outcome of previous cycle (spring 2018) of Information Systems Course that we teach on third year of bachelor degree. Each student receives a problem from random domain as an assignment, such as e-commerce, ticket booking, information system for school/university/library, mobile operator software platforms and many others. The task is to design and develop an information system according to the given requirements, using Java EE and MySQL technology. When it comes to object-relational mapping, JPA and Hibernate are used. However, the mapping issues are not the main focus of this course, so the students were not obliged to do complex relationship mappings. It was acceptable to implement just two tables, all the CRUD operations implemented and some of them used within the business logic functions. Despite the fact that the solutions' requirements and complexity may vary from case to

case, the project structure requirements common for all the assignments are:

- The project is based on Java EE technology[2]; it should be managed and built using Maven[3]
- MySQL[4] database server is used for data storage
- Hibernate/JPA should be used for object persistence using annotated entity classes
- Wildfly[5] is used as an application server
- Enterprise Java Beans (EJB)[6] is used for implementation of business logic
- A console client application that implements a usage scenario covering all the functional aspects of the application

For each of the previously given checkpoints, SPARQL queries were defined by the project evaluator to determine whether the conditions at the level of provided source code assets are satisfied. The architecture of the information system that has to be developed by students in our course is illustrated in Fig. 5.

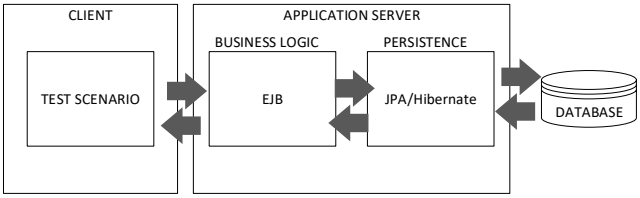

Fig. 5. Overview of the assignment for Information Systems course

VI. Evaluation and Results

In academic year 2017/18, we had 226 enrolled students. However, not all of them were able to complete the project, while some of them were disqualified due to plagiarism. Therefore, 200 students submitted the complete project, while two students among them had different assignments related to research work and were not relevant for this case study. For evaluation purposes, we have selected 50 student projects randomly from this set (out of 198) and imported into the automatic assessment platform.

In Table I., the evaluation results are given. The first column presents the name of each checkpoint that was scored within the project. The second column provides information about the maximum score that can be achieved for each of the checkpoints. The third column shows the average score for each of the checkpoints obtained during manual project evaluation by course instructor. On the other side, the fourth column displays the average results of automatic assessment platform for each of the checkpoints. Finally, the last column shows the absolute difference of the grades obtained manually and using automated assessment.

According to the results presented in Table I, it can be immediately noticed that the overall average score is lower in case of automatic assessment. The same stands for each checkpoint separately, except the last one, where the score obtained using our platform is higher than the case of manual evaluation. The automatic assessment platform was generally stricter than the evaluator due to fact there were some student files which were not parsed properly, due to wrong character formatting and syntax errors, especially when it comes to XML configuration files (the first two checkpoints), while these errors were still acceptable for human evaluator. On the other side, for the test scenario, the evaluation platform was less strict, due to fact that this part dramatically varies from case to case, making very difficult to automatically detect whether the student has implemented the most appropriate scenario for the considered information system and is graded more subjectively than other parts, when it comes to manual evaluation. Furthermore, in case of manual evaluation, the instructor has also considered the runtime aspects of the applications in the test scenario (running properly or no), while our platform performed solely static code analysis. Entity classes and ORM mapping checks perform quite well, with slightly lower grade than in case of manual assessment, also due to fact that some files were not parsed properly due to wrong text formatting. When it comes to EJB and business logic checkpoint, the highest grading difference has been noticed, as in case of human-based assessment also the complexity of the project was also considered, so the students have achieved some extra points despite the small errors in code.

The fact that the average grade is approximately 12,3% lower in case of automated assessment is acceptable, especially if we take into account that manual assessment by human evaluator lasted (in most cases) from 6 to 10 minutes for a single project, while it is around 90 seconds for the automatic assessment. Therefore, the assessment speed-up is at least 4 times. This is what makes the platform suitable for continuous assessment, as course instructors are not available 24 hours for tutoring of the students' projects, while the automatic assessment platform would be always available online.

TABLE I
Comparison of Average Grade Obtained Manually and Using Automatic Assessment Tool

Checkpoint	Max. points	Manual eval.	Auto-eval.	Grade diff.
Maven config	**3**	2.81	2.16	0.65
Deploy. config	**3**	2.32	1.75	0.57
Entity classes	**5**	4.12	3.78	0.34
EJB/business logic	**5**	4.41	2.92	1.49
Test scenario	**4**	3.08	3.67	0.69
Overall score	**20**	16.74	14.28	2.46

VII. Conclusion and Future Work

In this paper, a semantic approach to automatic assessment of students' programming assignments was presented. According to the evaluation results, it was shown that this approach was effective when it comes to assessment of student projects developed in context of Information Systems

[2]https://www.oracle.com/technetwork/java/javaee/overview/index.html

[5] http://wildfly.org/
[6] https://www.oracle.com/technetwork/java/javaee/ejb/index.html

course (third year of bachelor degree) at Faculty of Electronic Engineering, University of Nis. Despite the fact that the solution seems quite promising, there is still space for improvements in future.

First, the platform still lacks the implementation of the module that is responsible for runtime program evaluation. It is planned in near future to implement and integrate this module at it will be most probably based on JUnit framework. Despite that our platform performs quite well even relying only on static code analysis, our expectation is that the assessment accuracy will be increased, as we will include also the evaluation of behavioral aspects of the program.

Secondly, it is planned to adopt data mining techniques within the learning environment (as described in [14]) in order to enable adaptability and provide more sophisticated feedback to students based on their behavior patterns, combined with approach similar to [3].

Moreover, we would like to provide support for more programming languages and technologies, especially when it comes to Web programming. The efforts needed for adding the support for new technologies would involve parser construction and corresponding language-specific ontologies that would enable the semantic annotation of program code. It is also required to consider integration with plagiarism detection mechanisms at least within the scope of student project repository (including previous course cycles) that would ensure that students' solutions are original.

Finally, it is planned to use the extended version of the platform during the next cycle of Information Systems Course we teach (spring 2020), so the students will be able to have continuous feedback during the project development before the final evaluation done by the teachers. After that, we will compare the final course outcome with previous cycles where the automatic assessment tool was not used.

ACKNOWLEDGMENT

This work has received funding from the European Union's Horizon 2020 Framework Programme for Research and Innovation under the Grant Agreement No 645220, project RAWFIE (Road-, Air- and Water- based Future Internet Experimentation) and the Serbian Ministry of Education, Science and Technological Development (project III47003).

Secret keys generation from mouse and eye tracking signals

Milan Milosaljević, Saša Adamović, Aleksandar Jevremović

***Abstract* — This paper presents a new approach to generating cryptographic keys, based on local mutual randomness of mouse and eye move tracker sensor signals. The cross-correlation analysis of the longitudinal and transverse components of these sensor signals confirms a sufficient level of mutual randomness, which is originally the starting point for the protocol for generating secret cryptographic keys with the help of a public discussion. Experiments show that in this way you can generate random sequences of good cryptographic properties, with speed up to 20 bits/minute for the typical interaction with web pages.**

***Index Terms*— cryptographic keys, common randomness, eye tracker signals, mouse signals.**

I. Introduction

Generating random numbers has a long history in several different disciplines: from computer simulations of probabilistic phenomena [1], cryptography [2], to artificial intelligence [3]. In the latter case, the ability to generate random sequences is related to the free will of an artificial entity, and therefore its pretension to be fully human. In [3] generating random sequences is suggested as one possible test of artificial intelligence, similar to the Turing test [4]. Generating random strings for the needs of different cryptographical services is the central and most sensitive link in the cybersecurity chain [2]. Therefore, it is not surprising that the most relevant results from this domain appear in the field of cryptography. In this context, the seminal works of Ahlswede and Csiszár [5], Maurer [6] and Csiszár and Narayan [7] draw particular attention.

The basic idea of this approach is to extract signals of sufficiently large entropies on the physical layer of today's communication systems. There are two basic directions in this field, [6]:

(i) First, extracts these signals from sources independent of communication channels (source model),

(ii) Second, extracts these signals from the noise of the present communication channels (channel model).

As illustrated in Figure 1, a source model for secret-key agreement represents a situation in which three parties, Alice, Bob, and Eve, observe the realizations of a DMS - Discrete Memoryless Source (XYZ, P_{XYZ}) with three components. The DMS is assumed to be outside the control of all parties, but its statistics are known. By convention, component X is observed by Alice, component Y by Bob, and component Z by Eve. Alice and Bob's objective is to process their observations and agree on a key K about which Eve should have no information.

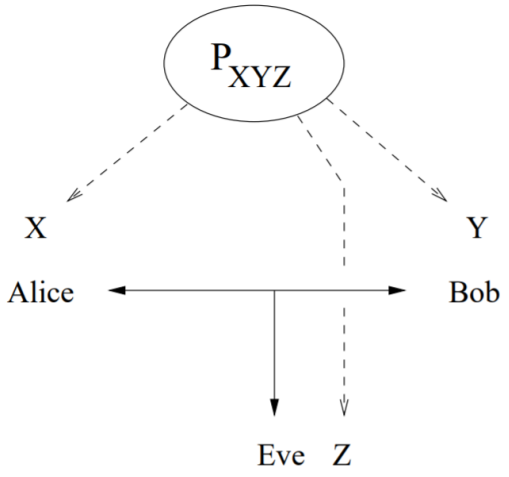

Fig.1. Secret-key agreement by Public Discussion from Common Information [7], [8].

Alice and Bob can exchange messages over a noiseless, two-way, public and authenticated channel. That is, all messages are overheard by Eve and the existence of the public channel does not provide Alice and Bob with an explicit advantage over Eve. The rules by which Alice and Bob compute the messages they exchange over the public channel and agree on a key define a four stage key distillation strategy, [9]:

1. *Randomness sharing*. Alice, Bob, and Eve observe n realizations of a DMS (XYZ, P_{XYZ}).

2. *Advantage distillation*. If needed, Alice and Bob exchange messages over the public channel to process their observations and to "distill" observations for which they have an advantage over Eve.

M. Milosavljevic is with the Technical Faculty, Singidunum University, Belgrade, Serbia E-mail: mmilosavljevic@singidunum.ac.rs

S.Adamović is with the Informatics and Computing Department, University Singidunum, Belgrade, Serbia E-mail: sadamovic@singidunum.ac.rs

A. Jevremović is with the Informatics and Computing Department, University Singidunum, Belgrade, Serbia E-mail: ajevremovic@singidunum.ac.rs

3. *Information reconciliation*. Alice and Bob exchange messages over the public channel to process their observations and agree on a common bit sequence.

4. *Privacy amplification*. Alice and Bob publicly agree on a deterministic function they apply to their common sequence to generate a secret key.

The largest achievable key rate is defined as key capacity and is given by

$$C_K=\max\{I(X;Y), I(X:Y|Z)\}, \quad (1)$$

where I(X;Y) denotes mutual information between X and Y, while I(X:Y|Z) denotes the same quantity conditioned by Z. In the special case, when Eva is totally independent from Alice and Bob, or equivalently, when Z is independent from X and Y, maximal key capacity is equal to

$$C_{k\,max} = I(X;Y). \quad (2)$$

Based on this facts, we propose application of key distillation protocol for generation of random sequences, based on DMS (XY, P_{XY}) with two components X and Y. Our primary goal is proof of proposed scheme when X and Y represents signals obtained from mouse cursor points and gaze tracker, measured during web browsing, see Fig.2.

II. Source of Randomness

To collect the eye tracking data, we used an inexpensive eye tracking device, made by a Danish startup company - The Eye Tri. The eye tracker was connected to a PC via USB3.0 interface. The technical specification of the eye tracker is the following:

- Sampling rate: 30 Hz
- Accuracy: 0.5° (average)
- Spatial resolution: 0.1° (RMS)
- Latency: < 20 ms at 60 Hz
- Calibration: 5, 9, 12 points
- Operating range: 45 cm – 75 cm
- Tracking area: 40 cm × 30 cm at 65 cm distance
- Screen sizes: Up to 24 inches
- API/SDK: C++, C# and Java included
- Data output: Binocular gaze data

The biggest advantage of the device used for our tests is its price - it costs around USD100. However, the low sampling rate makes this device unusable for analyzing the saccades, or for some other professional purpose (though, it is very effective for monitoring human-computer interaction). Some professional devices of this type provide a sampling rate of 1KHz (or even higher), so our assumption is that by using those devices the performances (in terms of time required to collect enough eye tracking data) of our solution would go up by more than sixteen times. However, having in mind that mouse movements are another limiting factor of the performance, this has to be verified experimentally.

The software used to collect the data from the eye tracking device was a combination of a custom Java-based desktop application (which was in charge of collecting gaze and mouse cursor points locally) and the HCI-MAP cloud-based platform [9]. The main purpose of using the HCI-MAP platform is to perform a time synchronization between the different sensors (eye trackers, EEG devices, applications, etc.), thus to collect the data from multiple sources in a time synchronized manner, and to use cloud computing resources to further process the data. However, for the real-life application of the approach proposed in this paper, all of the processing would be done locally, since there is no need for cloud-based processing, and the data should not leave a local computer because of the security reasons.

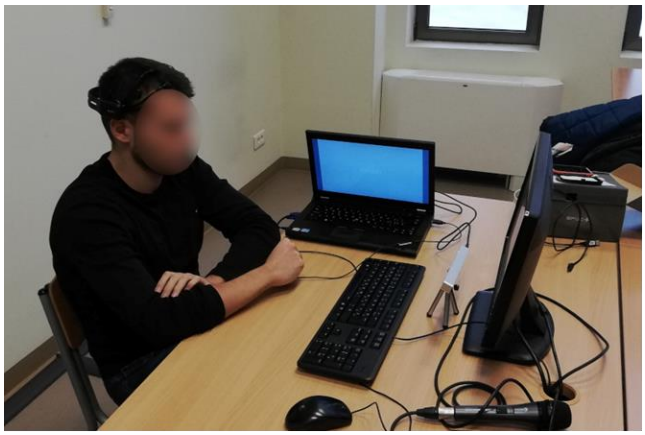

Fig. 2. Experimental settings during recording of measurement signals.

Our DMS is actually 4 dimensional (x_mouse,y_mouse,x_eye,y_eye), where (x_mouse,y_mouse) denotes coordinates of mouse pointer, while (x_eye,y_eye) measure coordinates of gaze.

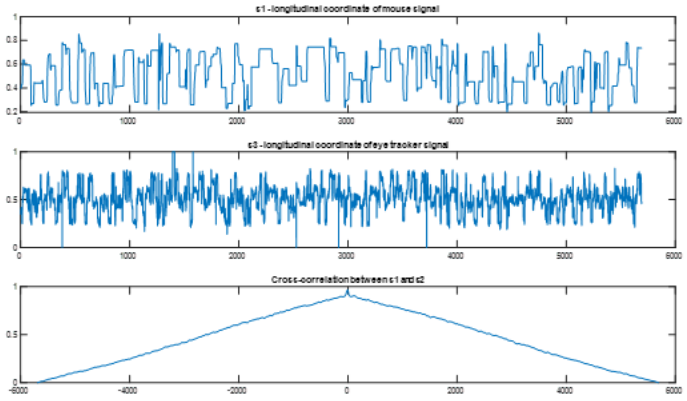

Fig. 3. Time domain behavior of tracking signals (longitudinal components) along with cross-correlation function. Time shift which maximizes cross correlation is found to be 5.

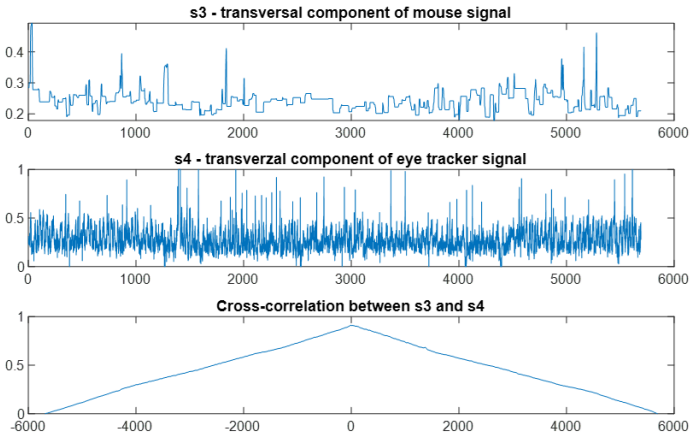

Fig. 4. Time domain behavior of tracking signals (transversal components) along with cross-correlation function. Time shift which maximizes cross correlation is found to be 4.

We show obtained signals in Fig.3 – Fig.6.

III. PROTOCOL

After measuring the tracker signals, its quantization and coding, four binary sequences are obtained at the Alice and Bob side. Then follow the standard steps of the source model secret-key agreement procedure, described at Introduction of this paper. As a measure of randomness we use Mean Shannon Block Entropy (MSBH), where average is taken over block size from 1 to 7. At the end of each round we apply a universal hash function [10], actually multiply given binary sequence with sparse random (0,1) matrix. Column-wise sparsity is 5%, while all algebraic operation are seen as operation over Galois Field GF(2).

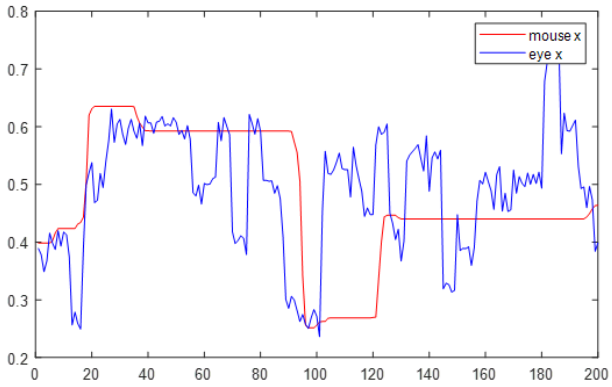

Fig. 5. Illustration of longitudinal components of tracking signals

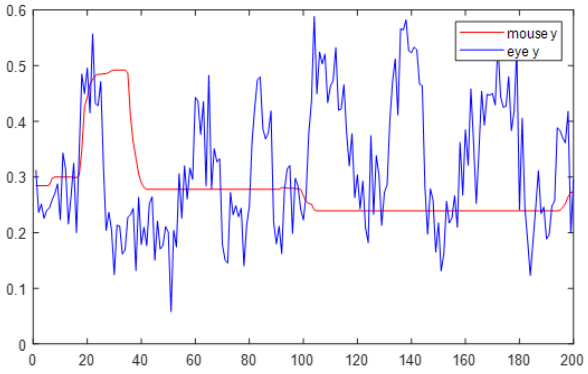

Fig. 6. Illustration of transversal components of tracking signals

IV. EXPERIMENTAL EVALUATION

Table I gives a summary of the basic results obtained for sensory signals (x_mouse, x_eye). Row named „Original“ denotes MSBH of rounds output, row named „Hashed“ stands for MSBH of universally hashed original sequences, while „Random“ denotes MSBH of random sequences generated by built in pseudorandom generator of MATLAB package of the same length.

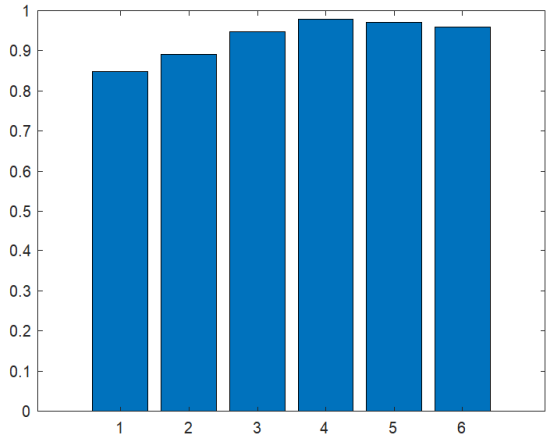

Fig. 7. Average Shannon block entropy evolution across 6 rounds of key distillation from x_mouse and x_eye signals.

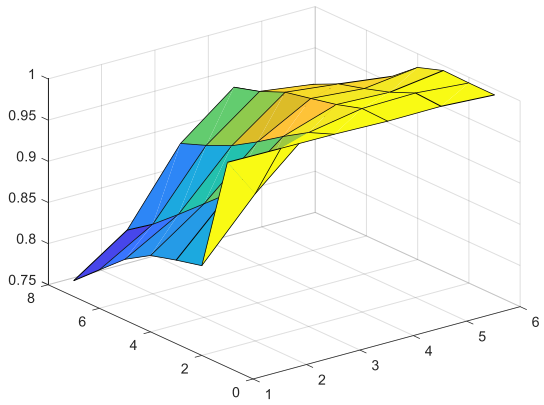

Fig. 8. Shannon block entropy evolution across 6 rounds and 1 to 7 block sizes of key distillation from x_mouse and x_eye signals.

Table I Summary of results for signals (x_mouse,x_eye)

	Round 1	Round 2	Round 3	Round 4	Round 5	Round 6
Original	0.8010	0.8140	0.8580	0.9430	0.9790	0.9740
Hashed	0.9946	0.9948	0.9943	0.9938	0.9889	0.9754
Random	0.9946	0.9947	0.9942	0.9932	0.9892	0.9723

Experimental results show that universal hashing purifies randomness. We introduce measure of gain in randomness obtained by universal hashing:

HashGain=sum((HM-HMHash)/sum(HMHash))*100 [%]

where HM means MSBE of original while HMHash denotes MSBE of hashed original.

The HahGain for pairs (x_mouse, x_eye) is - 4.9852 %. Negative sign means that hashing causes raising of randomness and consequently raising of MSBH.

From all this facts we can conclude, that proposed source of randomnes and distillation algorithm give sequences with very good random properties, even better than standard pseudorandom generators built in many famous software products, like MATLAB.

V. Conclusion

This paper presents a new protocol for generating secret cryptographic keys based on common randomness with an unlimited public discussion over an authenticated channel. The source of common randomness lies in the signals of mouse and eye tracker, which is not so rare in today everyday use. Experimental results prove feasibility of proposed approach. Obtained cryptographic keys are better at standard randomness tests compered to standard pseudo random generator approach.

Acknowledgment

This work has been supported by the Serbian Ministry of Education and Science (projects III44006, ON174008, III 47018 and TR32054). We would also like to thank prof. Panayiotis Zaphiris and prof. Andri Ioannou for providing us the eye tracker equipment and valuable advices for this research.

Klasifikacija akvatičnih larvi insekata korišćenjem duboke konvolucione neuronske mreže i prenesenog učenja

Aleksandar Milosavljević, Đurađ Milošević i Bratislav Predić

***Apstrakt*—U radu je opisan metod za klasifikaciju tri vrste larvi hironomida (*Chironomidae*: *Diptera*, *Insecta*) na osnovu slika dobijenih pomoću mikroskopa i binokularne lupe. Kao klasifikator je iskorišćena duboka konvoluciona neuronska mreža ResNet-50 arhitekture koja je obučavana na 80% skupa slika, dok je preostalih 20% korišćeno za validaciju. S obzirom na relativno mali broj trening uzoraka, primenjena je tehnika prenesenog učenja (eng. *transfer learning*), tako da se krenulo od mreže koja je prethodno obučena na ImageNet trening skupu uz promenu vršnog klasifikatora mreže. Obučavanje je vršeno u dve faze. U prvoj fazi je obučavan samo vršni klasifikator na osnovu karakteristika ekstrahovanih propuštanjem slika kroz prethodno istrenirani konvolucioni deo mreže. Nakon toga je vršeno „fino podešavanje" obučavanjem celokupne mreže. Da bi se dodatno anulirao problem male količine trening podataka, primenjene su tehnike proširivanja podataka (eng. *data augmentation*) i odbacivanja (eng. *dropout*). Primenom pobrojanih tehnika ostvarena je idealna klasifikacija kako trening tako i validacionog skupa. Odgovarajući rezultati su prezentovani u radu.**

***Ključne reči*—Duboko učenje; konvolucione neuronske mreže; klasifikacija slika; preneseno učenje; pojačavanje podataka; akvatični insekti; hironomida.**

I. Uvod

Klasifikacija slika predstavlja problem gde se na osnovu skupa slika za koje je poznata odgovarajuća kategorija izgrađuje model koji je u stanju da za neke nove slike predvidi kategoriju sa određenom tačnošću. Sam zadatak nije jednostavan zbog različitih varijacija koje su prisutne na slikama. Varijacije mogu biti u položaju kamere u odnosu na objekat, veličini objekta na slici, same varijacije u izgledu jedinki neke klase, deformacije slike, zaklanjanje od strane drugih objekata, razlike u osvetljenju, kao i sadržaj pozadine.

Za rešavanje ovog problema tipično se koristi pristup zasnovan na podacima. Umesto da pokušavamo da opišemo svaku od klasa koja treba da se identifikuje, koristimo veliki broj primera za svaku od klasa kako bi obučili određeni model (klasifikator) da bude u stanju da ih identifikuje. Da bi mogli da ocenimo kvalitet obučenog modela pri klasifikaciji novih uzoraka, od polaznog skupa se uzima određeni deo koji se koristi u svrhu validacije.

U našem slučaju, problem je identifikacija vrsta akvatičnih insekata koje su važne za procenu kvaliteta površinskih voda. Jedna od najznačajnijih grupa u biomonitoringu voda su larve iz familije *Chironomidae* (*Diptera*: *Insecta*). Velika raznolikost vrsta i značajna uloga u ekosistemu čini ovu grupu ključnom u procesu bioprocene. Međutim, komplikovana identifikacija vrsta u okviru hironomida koja je vremenski zahtevna, uz obavezno angažovanje eksperata, značajno poskupljuje njihovu implementaciju u rutinske monitoring programe, propisane pravnom regulativom svake države [1].

Tradicionalni pristup problemu klasifikacije slika se zasnivao na „ručnom" projektovanju različitih ekstraktora karakteristika slike (eng. *features*) na osnovu koji bi se obučavao klasifikator [2, 3, 4, 5]. Iako su se veštačke neuronske mreže i ranije koristile [6], veliki napredak u ovoj oblasti nastupa uvođenjem konvolucionih neuronskih mreža (KNM) [7]. KNM kombinuju tri arhitekturne ideje pomoću kojih se ostvaruje određeni nivo invarijantnosti na translaciju i distorziju: lokalna receptivna polja, deljene težina i prostorno poduzorkovanje (eng. *subsampling*) [8]. KNM dolaze u žižu interesovana 2012. godine nakon pobede mreže pod nazivom AlexNet [9] na takmičenju *ImageNet Large Scale Visual Recognition Challenge* [10] (u daljem tekstu skraćeno ImageNet). AlexNet je ostvarila top-5 grešku od 15,3% što je bilo za 10,8% bolje od drugo plasiranog rešenja. Ovakav rezultat je bio moguć zahvaljujući obučavanju korišćenjem grafičkih procesora (GPU) što se smatra prekretnicom za razvoj dubokog učenja (eng. *deep learining*). U nekoliko narednih godina zabeležen je drastičan napredak dubokih KNM i poboljšanje rezultata na ImageNet takmičenju. Pobednik 2013. je mreža ZFNet [11] sa top-5 greškom 14,8%. Značaj ovog rešenja je prevashodno u tehnici za vizuelizaciju mapiranjem naučenih filtara u slike. Naredna godina donosi veliki napredak i dva značajna rešenja. VGGNet [12] postiže top-5 grešku od 7,3% uz promovisanje jednostavnosti i dubine. Pobednik 2014. godine sa top-5 greškom od 6,7% je GoogLeNet [13] koji pored značajno boljeg rezultata beleži i smanjenje parametara za 12 puta u odnosu na AlexNet. Naredne godine ResNet [14] beleži top-5 grešku od 3,6% što je gotovo duplo bolji rezultat u odnosu na prethodnu godinu. ResNet arhitektra je inspirisana filozofijom VGGNet-a uz uvođenje rezidualnog pristupa u učenju kako bi se olakšalo

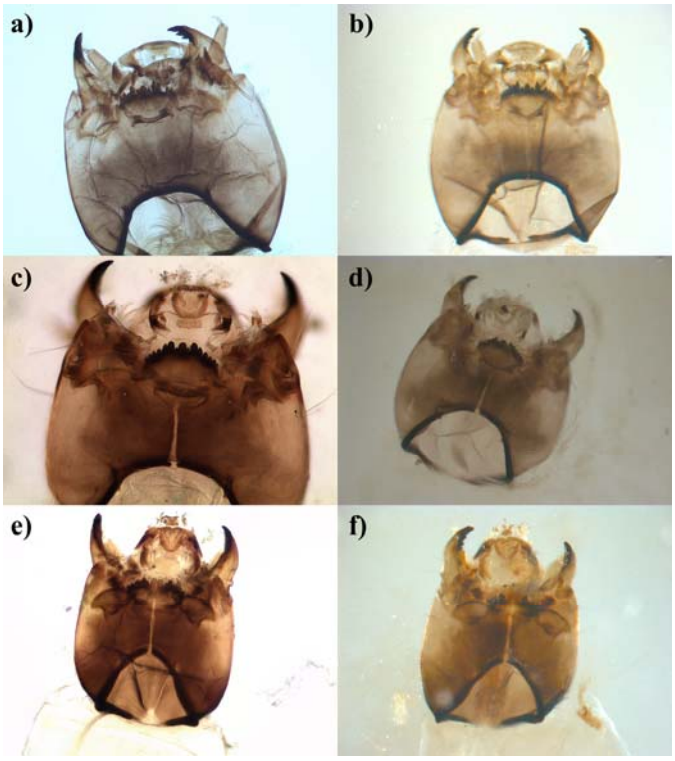
Bratislav Predić – Elektronski fakultet, Univerzitet u Nišu, Aleksandra Medvedeva 14, 18000 Niš, Srbija (e-mail: bratislav.predic@elfak.ni.ac.rs).

obučavanje dubokih mreža. Mreža koja je pobedila 2015. je varijanta ResNet-a sa 152 sloja. Za potrebe klasifikacije vrsta larvi hironomida mi smo koristili ResNet-50 varijantu koja ima 50 slojeva.

Značaj ImageNet takmičenja nije samo u originalnom zadatku koji podrazumeva klasifikaciju slika u 1000 kategorija. S obzirom da retko koja realna primena može da po broju uzoraka parira ImageNet skupu (oko 1.200.000 trening uzoraka), ideja je da se mreže utrenirane na ImageNet skupu koriste kao polazna osnova za dalje obučavanje. Odgovarajući pristup se naziva preneseno učenje (eng. *transfer learning*) [15, 16] i predstavlja osnovu predloženog rešenja.

Rad je organizovan na sledeći način: poglavlje 2 sadrži opis skupa podataka koji je korišćen i načina na koji je formiran. U poglavlju 3 dat je opis predloženog metoda uključujući i detalje konkretne implementacije. Ostvareni rezultati i odgovarajuća diskusija dati su u poglavlju 4. Konačno, u zaključku (poglavlje 5) je dat rezime i naznačeni su pravci daljeg istraživanja.



Sl. 1. Primeri slika glavenih čaura larvi hironomida (ventralni aspekt). Slike (a), (c) i (e) su načinjene pomoću mikroskopa, dok su slike (b), (d) i (f) dobijene korišćenjem lupe. Na slikama (a) i (b) su predstavnici vrste *Chironomus riparius*, na slikama (c) i (d) vrste *Chironomus nudiventris*, dok su na slikama (e) i (f) pripadnici vrste *Microtendipes pendellus*.

II. SKUP PODATAKA

Za analizu podataka korišćene su tri različite vrste larvi hironomida, i to dve vrste istog roda: *Chironomus riparius* (Meigen, 1804) i *Chironomus nudiventris* (Ryser, Scholl & Wuelker, 1983), dok je treća vrsta *Microtendipes pedellus* (De Geer, 1776), koja pripada istoj podfamiliji (*Chironominae*) kao prethodno navedene vrste. Pre fotografisanja, larve su kuvane u kalijum hidroksidu (KOH) kako bi se povećala elastičnost i sprečilo pucanje glavenih čaura prilikom montiranja mikroskopskih preparata. Korišćeno je 200 jedinki po taksonu i sve su pozicionirane tako da se obezbedi ventralni aspekt glavene čaure koji je najinformativniji u pogledu *species*-specifičnih morfoloških karakteristika. Svi identifikacioni ključevi, koji se baziraju na morfološkim karakteristikama koriste uglavnom strukture usnog aparata (*mentum*, *mandibule* i *labrum*) koje se nalaze na ventralnom delu glave hironomida. Nakon što su mikroskopski preparati montirani, usledilo je njihovo slikanje korišćenjem dva različita optička instrumenta sa kamerom: mikroskop i binokularna lupa (DM2500 Leica System microscope; Leica DFC490 digital camera, Wetzlar, Germany). U zavisnosti od veličine larve, svaka jedinka je zumirana tako da ceo objekat (glavena čaura) stane u vidno polje optičkog instrumenta. Na mikroskopu i lupi smo prilikom slikanja koristili uveličanje u opsegu od 60 do 100 puta. S obzirom da je prilikom fotografisanja korišćen 3D objekat (glavena čaura), upotrebili smo metodu „z-stack“ kako bi slika bila oštra u svim delovima vidnog polja. Tačnije nakon formiranja 6 slika istog objekta sa različitim uveličanjem, usledilo je spajanje slojeva po *z* osi.

Broj dobijenih slika po vrstama u zavisnosti od načina akvizicije prikazan je u Tabeli I. Podela skupa podataka na trening i validacioni skup je izvršena po principu 20% podataka se odvaja za validaciju. Da bi validacioni skup po strukturi oslikavao celokupan skup, za validaciju je izdvajan svaki peti uzorak za svaku od klasa i za svaki od metoda akvizicije (lupa i mikroskop). Pošto su isti uzorci slikani mikroskopom i lupom, za validaciju su birani uzorci čiji broj pri deljenju sa 5 nema ostatak. Odgovarajući broj ukupnih trening i validacionih uzoraka je takođe dat u Tabeli I.

TABELA I
STRUKTURA SKUPA PODATAKA

Vrsta	Br. slika mikroskop	Br. slika lupa	Br. slika za obučavanje	Br. slika za validaciju
Chironomus riparius	172	196	295	73
Chironomus nudiventris	190	189	304	75
Microtendipes pendellus	179	181	289	71

III. OPIS METODA

Ostvarivanje robusnosti u režimu ograničenog broja trening uzoraka nameće korišćenje sledećih tehnika pri projektovanju i obučavanju klasifikatora:

1. Preneseno učenje
2. Odbacivanje
3. Proširivanje podataka

Preneseno učenje predstavlja osnovnu tehniku koja omogućava korišćenje dubokih KNM za rešavanje problema sa relativno malim skupom podataka. Zasniva se na korišćenju prethodno utrenirane mreže na nekom velikom skupu podataka, kao što je npr. ImageNet skup. Treniranje na ImageNet skupu obezbeđuje da mreža izgradi hijerarhiju različitih karakteristika koje se mogu naći na fotografijama generalno i koje je pogodno iskoristiti za klasifikaciju novih fotografija. Da bi takav transfer bio moguć, potrebno je zameniti vršni deo mreže zadužen za klasifikaciju i utrenirati ga koristeći niz karakteristika koje identifikuje duboka KNM. Uobičajeno je da se deo KNM ispred klasifikatora naziva enkoder. U zavisnosti od prirode novog skupa ovakav pristup može da bude i sasvim dovoljan. Međutim, u našem slučaju ulazni podaci ne predstavljaju nešto što se tipično nalazi na fotografijama, zbog toga je bilo neophodno izvršiti dvofazno obučavanje. Nakon obučavanja klasifikatora u prvoj fazi, u drugoj fazi je vršeno fino podešavanje cele mreže. Fino podešavanje nije ništo drugu do obučavanja celokupne mreže, kako klasifikatora tako i enkodera. Termin fino se koristi da naznači korišćenje vrlo malih koeficijenata učenja kako bi se što manje narušile polazne vrednosti parametara.

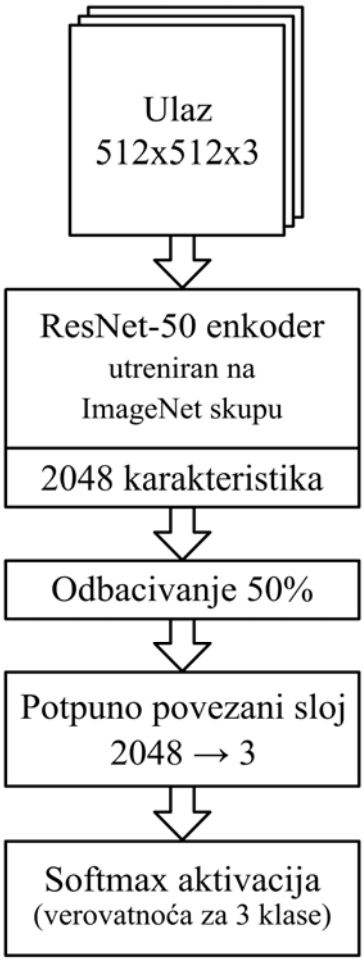
Druga tehnika koja je iskorišćena kako bi se povećala robusnost klasifikatora je odbacivanje [17]. Odgovarajući sloj je dodat nakon enkodera, tako da se u svakom koraku obučavanja odbacuje određen procenat (u našem slučaju 50%) karakteristika na osnovu kojih se vrši klasifikacija uzoraka. U fazi testiranja i eksploatacije mreže se uzimaju u obzir svi izlazi, ali se vrši skaliranje vrednosti za odgovarajući procenat odbacivanja. Na ovaj način se postiže u proseku isti nivo izlaza koji smo imali kod treniranja. Efekat koji se postiže primenom odbacivanja je da klasifikator mora da se oslanja na više različitih karakteristika pri određivanju kategorije. Na ovaj način se izbegava preterano prilagođavanje modela (eng. *overfitting*), a samim tim i bolji rezultati na validacionom skupu.

Obučavanje neuronske mreže da klasifikuje slike zahteva nalaženje karakteristika koje određuju odgovarajuće klase. Taj proces zahteva veliku količinu trening uzoraka kako bi se izolovale ključne karakteristike klasa i dobio klasifikator otporan na različite varijacije koje na slikama mogu da se jave. Kada imamo manju količinu trening podataka, a koristimo model velikog kapaciteta, dešava se model vrlo brzo „zapamti“ sve trening uzorke, ali zato daje loše rezultate na validacionom skupu. Tipično korišćena tehnika koja služi da se ovo izbegne je proširivanje podataka. Proširivanje podataka podrazumeva primenu nasumičnih transformacija nad ulaznim slikama tako da se u svakom trening ciklusu mreži predoči nešto što ranije nije „videla“. U zavisnosti od prirode skupa podataka, tipične transformacije uključuju okretanje, rotaciju, translaciju, skaliranje, zakošavanje, promenu osvetljaja i kontrasta, itd.

A. Arhitektura mreže

Vodeći se prethodno obrazloženim principima, za klasifikaciju larvi hironomida usvojena je arhitektura zasnovana na ResNet-50 [13] enkoderu prikazana na slici 2.

Na izbor ResNet-50 mreže utrenirane na ImageNet skupu kao enkodera je uticalo nekoliko faktora: dobri rezultati na ImageNet skupu, veličina mreže u pogledu broja parametara, memorijsko zauzeće u toku treniranja, brzina obučavanja, kao i dostupnost modela u korišćenom programskom okruženju. ResNet arhitektura generalno vrlo često predstavlja dobar inicijalni izbor zbog dobrog odnosa preciznosti i brzine obučavanja.



Sl. 2. Šematski prikaz korišćene arhitekture zasnovane na ResNet-50 mreži. Izlaz predstavlja raspodelu verovatnoća da je tekući uzorak primerak vrsta *Chironomus riparius*, *Chironomus nudiventris* i *Microtendipes pendellus*.

ResNet-50 enkoder poseduje 23.587.712 parametara, dok na izlazu daje 2048 karakteristika. Izlazi se dobijaju korišćenjem globalnog usrednjavanja (eng. *global average pooling*) po izlaznoj mapi karakteristika koja za korišćeni ulaz dimenzija 512x512 piksela iznosi 16x16x2048.

Na dobijenih 2048 izlaza iz enkodera se primenjuje odbacivanje sa faktorom 50%. Ovo u praksi znači da se u fazi obučavanja polovina, tj. 1024 nasumično izabranih izlaza postavi na nulu. Tako modifikovani izlazi enkodera se dovode na potpuno povezani sloj sa 3 neurona gde svaki izlaz odgovara jednoj klasi. Sloj poseduje 6.147 parametara koji se obučavaju u prvoj fazi. Na izlaze se primenjuje *softmax* aktivaciona funkcija (1) čime ovaj sloj dobija ulogu

klasifikatora karakteristika koje daje ResNet-50 enkoder. Izlazi *softmax* funkcije predstavljaju verovatnoće da je tekući uzorak pripadnik neke od klasa. Ovo praktično znači da pojedinačni izlazi imaju vrednosti iz intervala [0, 1] i da je zbir svih izlaza jednak 1.

$$S(y_i) = \frac{e^{y_i}}{\sum_j e^{y_i}}. \quad (1)$$

B. Implementacija i obučavanje mreže

Za implementaciju predložene arhitekture iskorišćen je programski jezik Python i biblioteka Keras [18]. Keras je biblioteka visokog nivoa koja definiše pojednostavljeni interfejs za implementaciju dubokih neuronskih mreža i u našem slučaju se oslanja na TensorFlow [19] biblioteku za realizaciju svih funkcionalnosti.

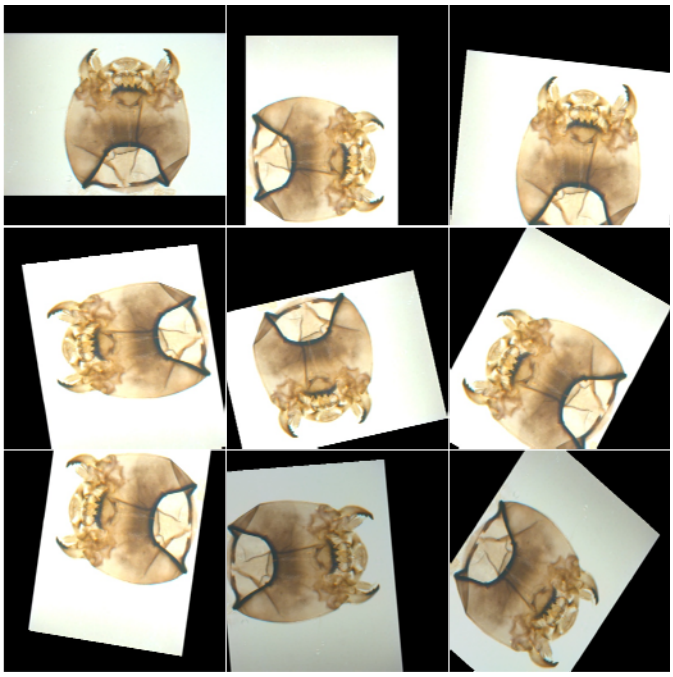
U okviru *applications* modula Keras poseduje nekoliko dubokih KNM arhitektura istreniranih na ImageNet skupu. Instanciranjem klase *ResNet50*, uz odgovarajuće parametre, dobijamo enkoder za naš model. Na izlaz enkodera se nadovezuje *Dropout* i *Dense* sloj sa *softmax* aktivacijom čime se dobija kompletan model. Kako se u prvoj fazi obučavanja težine ResNet-50 enkodera ne menjaju, potrebno je za sve konvolucione slojeve u enkoderu postaviti atribut *trainable* na *False*.

Kreirani model je kompajliran tako da koristi *Adam* [20] algoritam za optimizaciju (*optimizers* modul), *sparse_categorical_crossentropy* tip greške (*losses* modul), dok se kao metrika tačnosti koristi *sparse_categorical_accuracy* (*metrics* modul). Algoritam optimizacije je izabran zbog brze konvergencije, dok su greška za obučavanje i odgovarajuća metrika tačnosti standardni izbor za problem klasifikacije. Varijante ovih funkcija sa prefiksom *sparse_* se koriste kada se klase koje predstavljaju očekivani izlaz zadaju kao celi broj (0, 1 ili 2 u našem slučaju).

Za potrebe proširivanja podataka iskorišćena je Keras ugrađena klasa *ImageDataGenerator* koja se nalazi u *preprocessing* modulu, podmodul *image*. Pri konstruiranju odgovarajućeg generatora slika definišu se opsezi za različite transformacije koje će nasumično primenjivati. U našem slučaju korišćeno je horizontalno i vertikalno obrtanje slike, rotacija do ±90°, translacija do ±15% po oba pravca, promena osvetljaja do ±20%, zakošavanje i skaliranje do ±10%. Ilustracija je data na slici 3. Proširivanje podataka se vrši samo za trening skup, do za potrebe validacije koriste neizmenjene slike.

S obzirom da je korišćen generator slika, za obučavanje mreže koristi se metod *fit_generator*. Dodatna kontrola procesa obučavanja je u Kerasu moguća prosleđivanjem liste *callback* objekata. Odgovarajuće klase se nalaze u modulu *callbacks* i u našem slučaju iskorišćene su: *LearningRateScheduler*, *EarlyStopping*, *ModelCheckpoint* i *CSVLogger*.

LearningRateScheduler obezbeđuje definisanje proizvoljne funkcije za izmenu koeficijenta brzine obučavanja u zavisnosti od tekuće epohe obučavanja. U našem slučaju, ovaj *callback* je iskorišćen za implementaciju tzv. kosinusnog kaljenja (eng. *cosine annealing*) [21]. Kod kosinusnog kaljenja koeficijent obučavanja se smanjuje po kosinusnoj funkciji od neke inicijalne do neke minimalne vrednosti u toku određenog broja epoha koje su definisane periodom ponavljanja. U prvoj fazi obučavanja je korišćena perioda ponavljanja od 10 epoha, sa inicijalnim koeficijentom obučavanja u rasponu od 10^{-3} do 10^{-5}, uz smanjivanje 0,7 puta pri svakoj novoj periodi.



Sl. 3. Ilustracija proširivanja podataka. Prva slika (gore-levo) predstavlja ulaz, dok su ostale slike nastale primenom nasumičnih transformacija.

Kako ime sugeriše, *EarlyStopping callback* se koristi za ranije zaustavljanje procesa obučavanja ukoliko u određenom broju epoha nema napretka po određenom parametru. U našem slučaju je korišćeno 30 epoha i praćena je tačnost na validacionom skupu.

CSVLogger callback se koristi za snimanje greški i tačnosti nad trening i validacionim skupom u toku procesa obučavanja, a u cilju kasnije vizuelizacija ovog procesa.

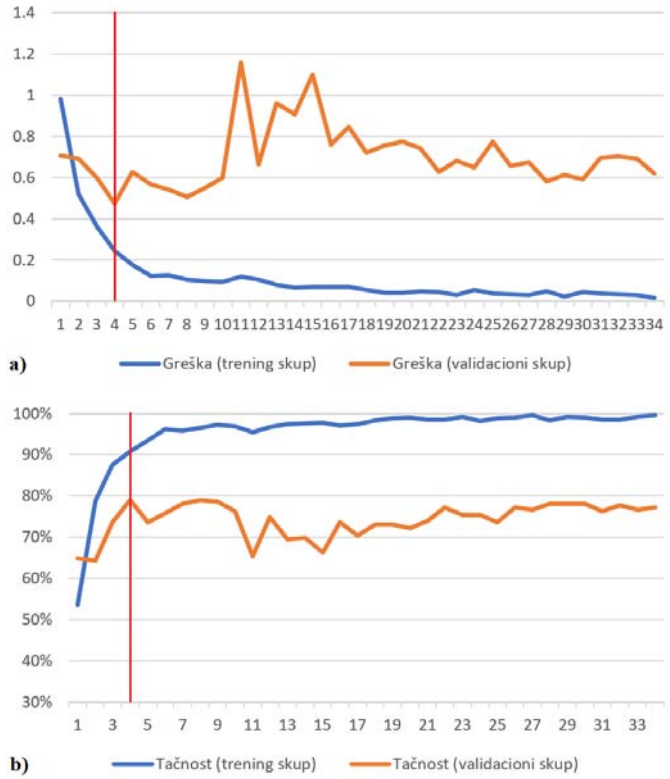
Konačno, *ModelCheckpoint* je iskorišćen za snimanje najboljeg rezultata u pogledu tačnosti postignute nad validacionim skupom. Ovako zabeležen model je iskorišćen za narednu fazu obučavanja, tj. fazu finog podešavanja.

Fino podešavanje je vršeno na gotovo identičan način, uz par sitnijih izmena. Nakon učitavanja modela dobijenog iz prve faze obučavanja, izvršeno je aktiviranje obučavanja za sve slojeve iz ResNet-50 enkodera (*trainable* atribut postavljen na *True*). Da bi se izbegla drastična izmena težina u enkoderu, koeficijent obučavanja se kretao u rasponu od 10^{-5} do 10^{-7}. Konačno, da bi se dobio model koji daje najbolje rezultate na celokupnom skupu podataka, umesto standardnog

validacionog, iskorišćen je kompletan neizmenjen skup podataka. Obučavanje je i dalje rađeno sa proširivanjem podataka trening skupa. Odgovarajući rezultati su prezentovani u narednom poglavlju.

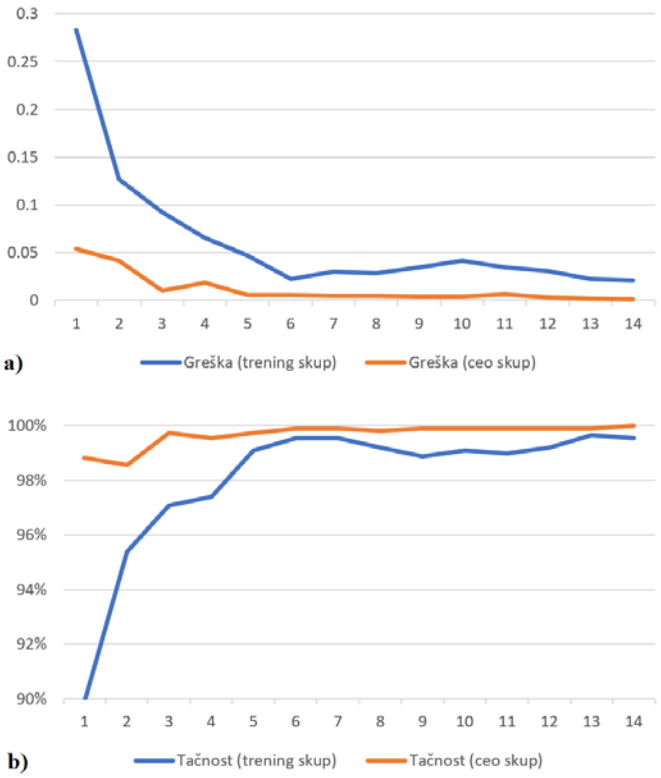
IV. Rezultati i diskusija

Tok obučavanja tokom prve faze prikazan je na slici 4. Prikazano je ukupno četiri grafikona: greška čija je minimizacija vršena i tačnost klasifikacije na trening i validacionom skupu. Obučavanje u prvoj fazi je vršeno u toku 34 epoha. Razlog za taj broj epoha je činjenica da je najbolja tačnost na validacionom skupu ostvarena već u 4 epohi, tako da je obučavanje prekinuto 30 epoha kasnije zbog *EarlyStopping*-a. Odgovarajući model je ostvario 78,99% na validacionom i 90,76% na trening skupu. Treba napomenuti da se zbog proširivanja podataka ne radi o originalnom trening skupu već nasumičnoj transformaciji istog u tekućoj epohi.



Sl. 4. Grafikon greške (a) i tačnosti klasifikacije (b) na nivou trening i validacionog skupa u toku prve faze obučavanja (obučavanje vršnog klasifikatora).

Druga faza obučavanja, fino podešavanje, kao polazni uzima prethodno dobijeni model. Inicijalno je za validaciju korišćen isti skup kao za prvu fazu, međutim pokazalo se da je mreža u stanju da ostvari idealnu klasifikaciju svih uzoraka iz ovog skupa. Ovakva situacija sprečava snimanje novih modela iako je bilo unapređenja na trening skupu. Da bi se izborili sa ovom situacijom, umesto validacije na prethodno definisanom validacionom skupu, vršena je validacija na celokupnom skupu podataka (unija validacionog i trening skupa). Za obučavanje je i dalje korišćen samo trening skup i vršeno proširivanje podataka, tako kod grafikona koji pokazuju tok obučavanja za drugu fazu (slika 5) imamo bolje rezultate za „validacioni“ skup od trening skupa. Razlog za ovu inverziju je i činjenica da se greška i tačnost na trening skupu dobija na osnovu podataka u toku obučavanja, dok se validacija vrši nakog završne epohe, pa je samim tim i mreža u datom trenutku utreniranija.



Sl. 5. Grafikoni greške (a) i tačnosti klasifikacije (b) na nivou trening i celokupnog skupa u toku druge faze obučavanja (fino podešavanje).

Gledajući grafikone za drugu fazu, moguće je uočiti da već nakon prve epohe dolazi do značajnog popravljanja tačnosti na celokupnom skupu (98,82%), dok nakon 14. epohe imamo idealnu klasifikaciju svih uzoraka (100%). Obučavanje je ručno zaustavljeno nakon toga.

V. Zaključak

U radu je opisan eksperiment čiji je cilj bio klasifikacija tri vrste larvi hironomida na osnovu slika dobijenih korišćenjem lupe i mikroskopa. Kao klasifikator iskorišćena je duboka KNM ResNet-50 arhitekture prethodno obučena na ImageNet skupu. Obučavanje je vršeno u dve faze. Prvo je obučavan samo vršni klasifikator, pa je nakon toga vršeno fino podešavanje celokupne mreže. Nakon druge faze su ostvareni idealni rezultati, tj. dobijen je model koji je u stanju da bez greške klasifikuje sve uzorke iz polaznog skupa podataka.

Sprovedeni eksperiment predstavlja samo polaznu studiju, sprovedenu na suženom skupu podataka koji sadrži uzorke

samo tri vrste (*Chironomus riparius*, *Chironomus nudiventris* i *Microtendipes pendellus*). Treba napomenuti da su prve dve vrste jako slične, te da je taj izbor namerno napravljen kako bi se ispitala mogućnost klasifikacije bliskih vrsta. Cilj eksperimenta je bio da pokaže da li primena KNM i dubokog učenja može da da dobre rezultate u detekciji larvi hironomida i kako različiti metodi akvizicije uzoraka utiču na rezultat. Ostvareni rezultati to i potvrđuju.

Dalja istraživanja će se fokusirati na metode za vizuelizaciju karakteristika na osnovu koji se KNM opredeljuje za neku klasu. Takođe, u planu je i proširivanje skupa podataka u pogledu broja klasa, ali i načina pripreme uzoraka.

ZAHVALNICA

Prikazani rezultati dobijeni su u okviru istraživanja na projektima III-43007 i III-47003 koje finansira Ministarstvo prosvete, nauke i tehnološkog razvoja Republike Srbije.

ABSTRACT

In this paper we proposed a method for classification of three species of aquatic insect larvae based on images acquired using microscope and binocular magnifier. As a classifier we used deep convolutional neural network with ResNet-50 architecture. The network was trained using 80% of the sample images while the rest 20% were used for validation. Considering relatively small number of training samples we applied a technique called transfer learning, i.e. we started with a network pretrained on ImageNet set while only changing its top classifier. Training process went in two phases. In the first phase we only trained top classifier based on the features extracted processing images with pretrained convolutional part of the network. After that, we "fine-tuned" the network by training it as a whole. To further tackle the problem of relatively small number of training samples we applied data augmentation and dropout techniques. Using proposed method, we achieved ideal classification for both training and validation sets. The results are reported in the paper.

Classification of aquatic insect larvae using deep convolutional neural network and transfer learning

Identifikacija naslaga soli na seizmičkim snimcima korišćenjem metoda dubokog učenja za semantičku segmentaciju

Aleksandar Milosavljević

***Apstrakt*—Nekoliko oblasti u svetu koje su bogate naftom i zemnim gasom takođe poseduju velike naslage soli ispod površine. Zbog ove veze, otkrivanje preciznih lokacija naslaga soli je izuzetno značajno za kompanije koje se bave istraživanjem nalazišta ovih energenata. Lociranje naslaga soli se vrši na osnovu profesionalnih seizmičkih snimaka koje kasnije analiziraju ljudski eksperti. Rezultati ovakve analize često variraju i podložni su subjektivnosti eksperta koji analizu sprovodi. U cilju automatizacije ovog procesa i postizanja bolje preciznosti, kompanija TGS je sponzorisala takmičenje na Kaggle platformi održano u drugoj polovini 2018. godine [1]. Takmičenje je okupilo 3234 pojedinaca i timova, a u radu su prezentovani rezultati i iskustva autorovog učešća (446 pozicija). Metod predložen u radu se zasniva na obučavanju duboke konvolucione neuronske mreže za semantičku segmentaciju. Arhitektura korišćene mreže je inspirisana U-Net modelom u kombinaciji sa ResNet i DenseNet arhitekturama.**

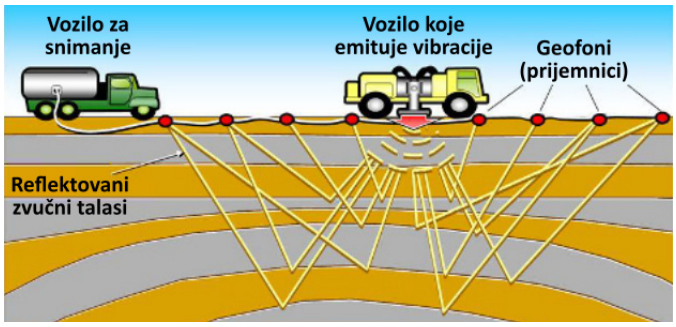
***Ključne reči*—Duboko učenje; konvolucione neuronske mreže; semantička segmentacija; seizmički snimci; naslage soli.**

I. Uvod

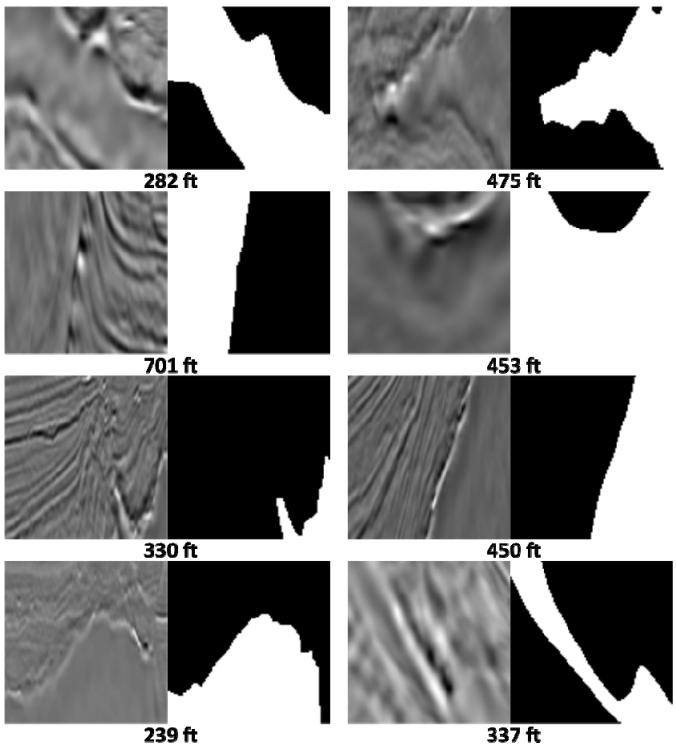
Seizmičko snimanje obezbeđuje vizuelizaciju podzemnih struktura i osnovna namena mu je otkrivanje potencijalnih nalazišta nafte i zemnog gasa. Zasniva se na emitovanju zvučnih talasa koji se odbijaju o podzemne strukture i bivaju detektovani na površini korišćenjem prijemnih uređaja koji se nazivaju geofoni (vidi sliku 1) [2]. Reflektovani zvučni signali se snimaju i kasnije obrađuju kako bi se dobili seizmički snimci koji predstavljaju 3D reprezentacije podzemnih struktura [3]. Seizmički snimci prikazuju granice između različitih tipova stena. Teorijski gledano, jačina odbijenog signala je direktno proporcionalna razlici fizičkih svojstava stena na mestu dodira. Ovo praktično znači da seizmički snimci sadrže informacije o granicama stenovitih naslaga, dok o samim stenama govore vrlo malo [1].

Otkrivanje rezervi nafte i zemnog gasa na osnovu seizmičkih snimaka se zasniva na otkrivanju rezervoarskih stena i u tom pogledu naslage soli igraju značajnu ulogu. Sedimenti soli poseduju karakteristike koje ih čine i jednostavnim i složenim za identifikaciju. Gustina soli je obično oko 2,14 g/cm^3 što je manje od većine obližnjih stena. Seizmička brzina soli je 4,5 km/s, što je obično brže od okolnih stena. Ova razlika uslovljava oštru refleksiju na granici sedimenta soli. Sediment soli je obično amorfnog oblika bez neke specijalne interne strukture, što znači da tipično nema mnogo refleksije unutar samog sedimenta sem ako ne potiče od drugih stena koje su tu zarobljene [1].

Aleksandar Milosavljević – Elektronski fakultet, Univerzitet u Nišu, Aleksandra Medvedeva 14, 18000 Niš, Srbija (e-mail: aleksandar.milosavljevic@elfak.ni.ac.rs).



Sl. 1. Ilustracija principa dobijanja seizmičkih snimaka.



Sl. 2. Primer nekoliko isečaka seizmičke slike, odgovarajućih maski koje definišu sedimente soli (bela boja) i dubina.

Zadatak Kaggle-ovog takmičenja koje je sponzorisala kompanija TGS je bio izrada algoritma koji je u stanju da na osnovu zadatih isečaka seizmičke slike dimenzija 101x101 svaki od piksela klasifikuje kao so ili ne-so. U cilju obučavanja modela obezbeđeno je 4000 isečaka seizmičkih slika i odgovarajuće informacije o tome gde se na slici nalazi so. Testiranje i ocena modela je vršena na 180000 isečaka. Pored samih slika i maski, za svaki od isečaka je obezbeđena informacija o dubini (u fitima) lokacije uzorka. Na slici 2 prikazano je nekoliko parova slika i maski.

Način na koji je postavljen, svrstava problem takmičenja u semantičku segmentaciju. Semantička segmentacija je jedan od ključnih problema računarskog vida i predstavlja naredni korak nakon klasifikacije slike i lokalizacije objekata na slici. Sva tri pobrojana problema se danas veoma uspešno rešavaju korišćenjem dubokih konvolucionih neuronskih mreža (KNM), te je i rešenje predloženo u radu zasnovano na toj tehnologiji.

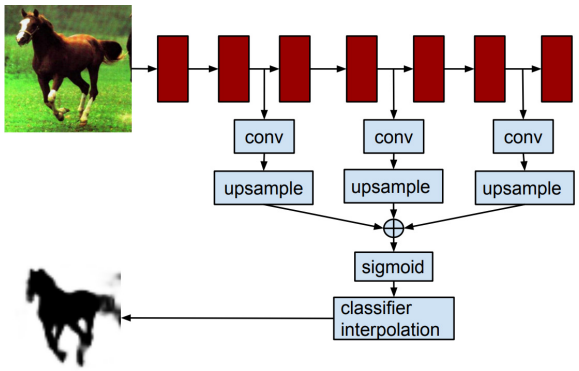
Rad je organizovan na sledeći način: poglavlje 2 sadrži opis postojećih rešenja iz oblasti semantičke segmentaciju i identifikacije naslaga soli. U poglavlju 3 dat je opis predloženog metoda u pogledu arhitekture KNM i detalja konkretne implementacije. Ostvareni rezultati i odgovarajuća diskusija dati su u poglavlju 4, nakon čega sledi zaključak u poglavlju 5.

II. Pregled postojećih rešenja

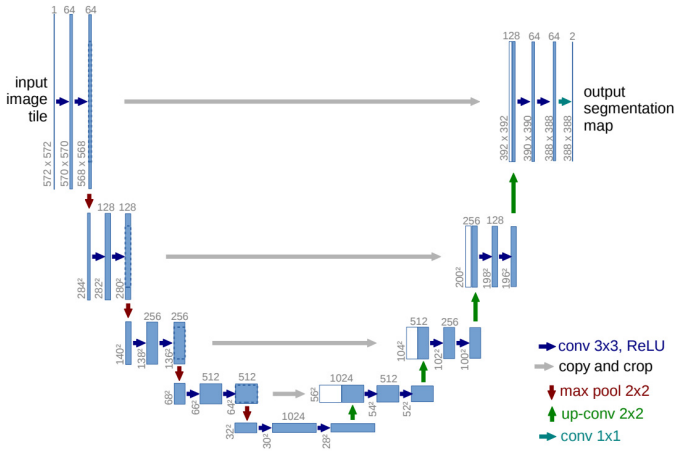
Problem analize seizmičkih slika i identifikacije soli zaokuplja pažnju velikog broja istraživača. Tipično za sve probleme računarskog vida, tradicionalni pristup analizi seizmičkih slika se zasnivao na „ručnom“ projektovanju različitih ekstraktora karakteristika (eng. *features*) i njihovoj kasnijoj analizi. U jednom od prvih radova iz ove oblasti, Pitas i Kotropoulos [4] su predložili metod zasnovan na analizi teksture u cilju segmentacije seizmičkih slika. Metodi zasnovani na korišćenju teksturnih atributa su aktuelni i u novije vreme [5, 6]. Harper i Clapp [7] su predložili proračun i korišćenje različitih seizmičkih atributa za identifikaciju naslaga soli. Izvođenje novih atributa seizmičke slike je pristup korišćen i u radu [8]. Analiza 3D seizmičkih slika je predmet istraživanja datih u [9, 10, 11]. Amin i Deriche [9] predlažu metod zasnovan na korišćenju 3D multidirekcionog detektora ivice. Wu [10] se oslanja na proračun verovatnoće da je nešto so u cilju identifikacije granice naslaga. Di *et al.* [11] predlažu višeatributnu klasterizaciju upotrebom k-means algoritma u cilju identifikacije granice sedimenta soli. Upotreba mašinskog učenja za identifikaciju četiri karakterističnih seizmičkih struktura na bazi različitih seizmičkih atributa ekstraktovanih iz slike je predložena od strane Wrona *et al.* [12].

Primena KNM [13] i dubokog učenja je dovelo do velikih pomaka u poslednjih nekoliko godina u nekoliko oblasti računarskog vida. KNM kombinuju tri arhitekturne ideje pomoću kojih se ostvaruje određeni nivo invarijantnosti na translaciju i distorziju: lokalna receptivna polja, deljene težina i prostorno poduzorkovanje (eng. *subsampling*) [14]. Duboke KNM su sposobne da izgrađuju hijerarhiju karakteristika koja ih čini pogodnim kako za klasifikaciju, tako i za lokalizaciju i semantičku segmentaciju objekata na slikama. Duboke KNM dolaze u žižu interesovana 2012. godine nakon pobede mreže pod nazivom AlexNet [15] na takmičenju *ImageNet Large Scale Visual Recognition Challenge* [16] (u daljem tekstu skraćeno ImageNet). AlexNet je ostvarila top-5 grešku od 15,3% što je bilo za 10,8% bolje od drugoplasiranog rešenja. Ovakav rezultat je bio moguć zahvaljujući obučavanju korišćenjem grafičkih procesora (GPU) što se smatra prekretnicom za razvoj dubokog učenja (eng. *deep learining*). U nekoliko narednih godina zabeležen je drastičan napredak dubokih KNM i poboljšanje rezultata na ImageNet takmičenju. Pobednik 2013. je mreža ZFNet [17] sa top-5 greškom 14,8%. Značaj ovog rešenja je prevashodno u tehnici za vizuelizaciju mapiranjem naučenih filtara u slike. Naredna godina donosi veliki napredak i dva značajna rešenja. VGGNet [18] postiže top-5 grešku od 7,3% uz promovisanje jednostavnosti i dubine. Pobednik 2014. godine sa top-5 greškom od 6,7% je GoogLeNet [19] koji pored značajno boljeg rezultata beleži i smanjenje parametara za 12 puta u odnosu na AlexNet. Naredne godine ResNet [20] beleži top-5 grešku od 3,6% što je gotovo duplo bolji rezultat u odnosu na prethodnu godinu. ResNet arhitektra je inspirisana filozofijom VGGNet-a uz uvođenje rezidualnog pristupa u učenju kako bi se olakšalo obučavanje dubokih mreža. Mreža koja je pobedila 2015. je varijanta ResNet-a sa 152 sloja.

Značaj KNM za klasifikaciju je u tome što se sa relativno malim izmenama mogu primeniti na problem semantičke segmentacije. Potpuno konvoluciona mreža [21] predstavlja upravo takvo rešenje. Zasniva se povećavanju prostorne dimenzije (eng. *upsampling*) mape karakteristika poslednjeg sloja i direktno preslikavanje u piksele mape segmenata. S obzirom da je prostorna komponenta poslednjeg konvolucionog sloja dosta gruba, u cilju dobijanja preciznijih rezultata moguće je formirati hiperkolonu [22] korišćenjem uvećanih konvolucionih mapa različitih dimenzija i obučavati izlaz na osnovu nje (vidi sliku 3). Dodatni konvolucioni sloj ispred sloja za uvećanje služi da izjednači broj kanala kako bi odgovarajuće mape mogle da se saberu i klasifikuju u na nivou svakog piksela.



Sl. 3. Semantička segmentacija korišćenjem hiperkolone (preuzeto iz [22]). Slojevi originalne KNM za klasifikaciju su prikazani crvenom bojom.



Sl. 4. U-Net arhitektura za semantičku segmentaciju (preuzeto iz [24]).

Nešto složenije arhitekture KNM za segmentaciju su predložene u [23] pod nazivom DeconvNet i u [24] pod nazivom U-Net. Na slici 4 prikazana je arhitektura U-Net mreže. Mreža poseduje enkoderski (leva strana) i dekoderski (desna strana) deo. Svaki dekoderski blok započinje konkatenacijom mape dobijene iz odgovarajućeg enkoderskog bloka i uvećane mape iz prethodnog dekoderskog bloka. Sa određenim izmenama, ovakva arhitektura je korišćena i u radu [25].

Zbog dobrih rezultata u drugim oblastima, primena dubokih KNM postaje podrazumevani izbor istraživača u oblasti segmentacije seizmičkih slika i identifikacije naslaga soli. Veliki broj radova [26, 27, 28, 29, 30, 31, 32, 33] u prošloj i tekućoj godini svedoči u korist te tvrdnje. Posebno bih istakli rad autora Babakhin *et al.* [33] koji opisuje prvoplasirano rešenje na TGS-ovom takmičenju [1].

III. Opis metoda

Pre nego se detaljnije pozabavimo opisom konkretnog rešenja, trebalo bi reći par reči o samom takmičenju. Sva Kaggle takmičenja imaju jasno definisano trajanje, pravila, podatke i metriku po kojoj se vrši evaluacija predloženih rešenja. U slučaju TGS-ovog takmičenja skup podataka za obučavanje se sastojao od 4000 slika dimenzija 101x101 i odgovarajućih segmentacionih maski. Test skup čini 180000 slika na osnovu kojih je potrebno predložiti maske čiji kvalitet se evaluira. Podaci o dubini u fitima su dostupni kako za trening tako i za test slike. Rezultati se prosleđuju u vidu CSV fajla gde se za svaku sliku iz test skupa maska kodira po *run-length encoding*-u.

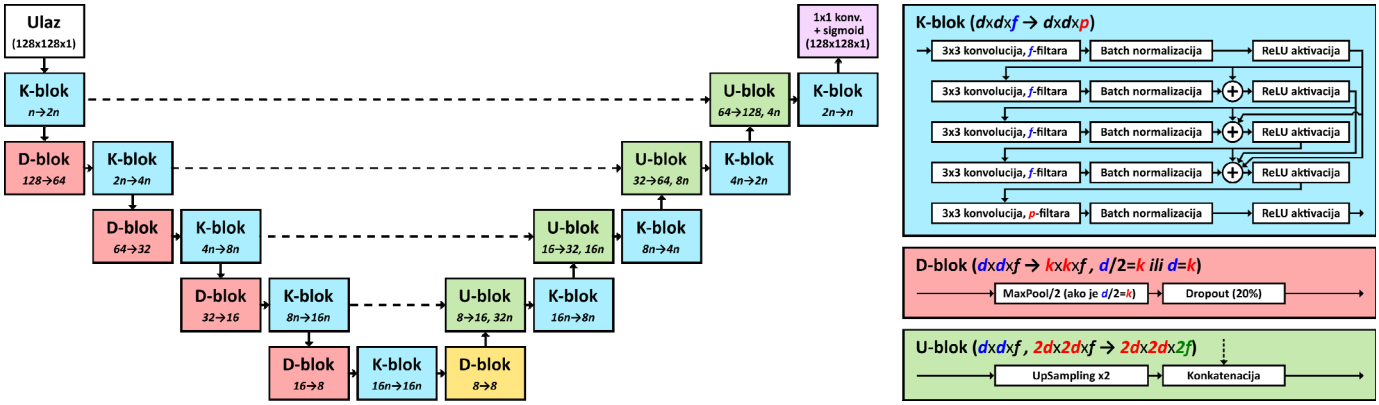
Takmičenje je trajalo od 19. jula do 20. oktobra 2018. godine. Svakog dana je moguće poslati maksimalno 5 rešenja za koje se dobija ocena po metrici koja je definisana za takmičenje. Ocena se vrši na osnovu 34% test podataka i najbolji rezultat određuje poziciju takmičara na javnoj rang listi. Konačni rezultati se objavljuju nakon završetka takmičenja na bazi preostalih 66% test podataka. Ocenjuju se samo dva predložena rešenja koje takmičar izabere. Bolja ocena određuju plasman na konačnoj (privatnoj) rang listi. Napomenimo da je do nedelju dana pre kraja takmičenja moguće vršiti spajanje učesnika u timove čime se njihovi pojedinačni rezultati objedinjuju.

Glavna prednost ovakve organizacije takmičenja je mogućnost da se za kratko vreme isproba i dobije neposredna ocena za veliki broj ideja, kao i da se vidi kvalitet sopstvenog rešenja u odnosu na ostale učesnike uz visok nivo objektivizma.

A. Arhitektura mreže

Na slici 5 je prikazana arhitektura mreže koja predstavlja konačno, tj. najbolje plasirano rešenje autorovog učešća na TGS-ovom takmičenju. Rešenje je zasnovano na U-Net [24] arhitekturi, zapravo je i nastalo modifikacijama U-Net mreže u želji da se popravi rezultat.

Kao što se sa slike 5 vidi, mreža se sastoji od tri tipa blokova (K, D i U). K-blok je najzastupljeniji i ujedno najsloženiji. U osnovi se sastoji se iz 5 konvoluciona sloja veličine kernela 3x3. Generiše se na osnovu dva parametra: ulazni broj filtara (*f*) i izlazni broj filtara (*p*). Prva četiri sloja imaju isti broj filtara (*f*) i „čvrsto su spregnuti“ operacijama sabiranja pre primene ReLU aktivacije, dok poslednji, peti, sloj ima *p* filtara i praktično služi da prilagodi broj filtara željenom izlazu. Specifična sprega slojeva sabiranjem izlaznih mapa je inspirisana ResNet [20] i DenseNet [34] arhitekturama, mada način na koji je izvedena predstavlja



Sl. 5. Prikaz arhitekture predložene KNM za segmentaciju naslaga soli. Mreža se sastoji iz tri tipa blokova (K, D i U) koji su detaljno prikazani sa desne strane. Konačni izlaz mreže se dobija 1x1 konvolucijom, sa jednim filtrom i sigmoidalnom aktivacijom na izlazu. Inicijalni broj filtara je označen sa *n*.

originalni doprinos. Pored konvolucionih slojeva, K-blok uključuje i *batch* normalizaciju i ReLU aktivaciju. Konkretan broj filtara u konvolucionim slojevima K-blokova je određen parametrom *n* koji predstavlja broj filtara u prvom konvolucionom sloju. Vrednosti sa kojima se eksperimentisalo su 16, 24 i 32.

D-blok predstavlja drugi korišćeni tip, a odgovarajući blokovi se nalaze u enkoderskog delu mreže nakon K-blokova. Namena D-bloka je duplo smanjivanje prostorne dimenzije korišćenjem *MaxPool* operacije (izuzetak je poslednji D-blok) i odbacivanje (eng. *dropout*) od 20% u cilju povećanja robusnosti mreže. Odbacivanje se primenjuje samo u fazi obučavanja mreže i predstavlja anuliranje određenog procenta elemenata mape karakteristika koja se dobija nakon operacije smanjivanja.

U-blok je pandan D-bloku u dekoderskom delu mreže. Namena mu je duplo uvećanje prostorne dimenzije mape karakteristika (*UpSampling* operacija) prostim ponavljanjem svake kolone i reda. Drugi zadatak ovog bloka je konkatenacija ovako uvećane mape se izlaznom mapom odgovarajućeg enkoderskog K-bloka (prikazano isprekidanim linijama), a u duhu U-net arhitekture.

Konačni izlaz mreže se formira na osnovu izlaza poslednjeg K-bloka primenom 1x1 konvolucije sa jednim filtrom i sigmoidalne aktivacione funkcije koja obezbeđuje izlaz u opsegu (0, 1) za svaki piksel. Pri formiranju prediktovane maske se odgovarajuće vrednosti zaokružuju na 0 ili 1.

B. Implementacija i obučavanje mreže

Za implementaciju predložene arhitekture iskorišćen je programski jezik Python i biblioteka Keras [35]. Keras je biblioteka visokog nivoa koja definiše pojednostavljeni interfejs za implementaciju dubokih neuronskih mreža i u našem slučaju se oslanja na TensorFlow [36] biblioteku za realizaciju svih funkcionalnosti. Konkretna implementacija koristi Kerasov funkcionalni API, a svaki blok je implementiran u posebnoj Python funkciji.

Od polaznog skupa trening podataka 80% slika je korišćeno za obučavanje, dok je preostalih 20% korišćeno za validaciju. Konkretno, podaci su deljeni u 5 podskupova, pa je obučavano 5 mreža, tako što je u svakoj od njih drugi podskup biran kao validacioni. Konačna predikcija je dobijena nalaženjem srednje vrednosti izlaza svih 5 mreža nakon čega je vršeno zaokruživanje. Da bi trening i validacioni skupovi sadržali reprezentativne podatke polaznog skupa, podeli na 5 podskupova je prethodilo sortiranje uzoraka po broju piksela soli na maski. Nakon toga je raspodela vršena dodelom svakog petog uzorka odgovarajućem podskupu.

Proširivanje podataka (eng. *data augmentation*) je vršeno i u fazi treniranja i u fazi pripreme rezultata. U fazi testiranja, proširivanje je vršeno na dva nivoa. Prvi nivo podrazumeva dupliranje uzoraka iz trening i validacionog skupa tako što se svaka slika i odgovarajuća maska preslikaju po vertikalnoj osi. Drugi nivo podrazumeva nasumične transformacije prostorne translacije, te skaliranje i pomeranje intenziteta. Prostorna translacija koristi osobinu da su slike veličine 101x101, dok je ulaz mreže 128x128. U 25% slučajeva slika se centrira po sredini (translacija od 13 piksela po ove ose). U ostalih 75% slučajeva se slika translira za proizvoljnu vrednost iz opsega 0–27 po jednoj i drugoj osi. Odgovarajuća translacija se vrši i sa odgovarajućom maskom. Popuna ostatka mape se vrši preslikavanjem u ogledalu vrednosti iz slike, odnosno maske. Transformacija intenziteta „skaliranje“ podrazumeva množenje intenziteta slike nasumičnom vrednošću iz opsega 0,8–1,2, dok transformacija „pomeranje“ podrazumeva dodavanje nasumične vrednosti iz opsega ±0,2.

Proširivanje podataka u fazi pripreme rezultata funkcioniše na sledeći način. Za svaku sliku iz test skupa nalazi se odziv mreže za originalnu i preslikanu sliku po vertikalnoj osi. Drugi odziv se preslikava, sabira sa originalnim i odgovarajući rezultat se deli sa 2. Ukoliko se vrši procena maski korišćenjem ansambla mreža, rezultati za svaku od mreža se snimaju (bez zaokruživanja), pa se naknadno usrednjavaju i zaokružuju kako bi se dobile konačne maske.

Obučavanje mreže je vršeno korišćenjem *Adam* [37] algoritma za optimizaciju (modul *optimizers*) i *binary_crossentropy* tipa greške (*losses* modul). Kao metrika tačnosti za izbor najboljeg rešenja korišćena je *binary_accuracy* funkcija iz *metrics* modula. Ova metrika u osnovi pokazuje koliko je piksela procentualno tačno klasifikovano. U informativne svrhe, praćena je i metrika zasnovana na odnosu preseka i unije pozitivnih piksela (eng. *Intersection over Union – IoU*).

Kontrola procesa obučavanja vršena je korišćenjem *callback* objekata. Odgovarajuće klase se nalaze u modulu *callbacks* i u našem slučaju iskorišćene su: *ReduceLROnPlateau*, *EarlyStopping*, *ModelCheckpoint* i *CSVLogger. ReduceLROnPlateau* obezbeđuje smanjivanje koeficijenta brzine obučavanja za zadati faktor ukoliko u određenom broju epoha nema napretka po određenom parametru. U našem slučaju praćena je tačnost na validacionom skupu, a koeficijent obučavanja je množen sa 0,1 ukoliko nema progresa nakon 10 epoha. Inicijalna vrednost koeficijenta je bila 10^{-3}. Za ranije zaustavljanje procesa obučavanja korišćen je *EarlyStopping callback* koji koristi sličan mehanizam. U našem slučaju je čekalo se 30 epoha ukoliko nema unapređenja tačnosti na validacionom skupu da bi se proces obučavanja zaustavio. *CSVLogger callback* se koristi za snimanje greški i tačnosti nad trening i validacionim skupom u toku procesa obučavanja, a u cilju kasnije vizuelizacija ovog procesa. Konačno, *ModelCheckpoint* je iskorišćen za snimanje najboljeg modela u pogledu tačnosti postignute nad validacionim skupom.

IV. REZULTATI I DISKUSIJA

Pre diskusije ostvarenih rezultata, potrebno je da se upoznamo sa metrikom po kojoj su vrednovani rezultati. Na takmičenju je korišćena metrika koja se zasniva na usrednjavanju IoU vrednosti po 10 pragova od 0,5 do 0,95 sa korakom 0,05. Tako, na primer, na pragu 0,5 prediktovani objekat se računa kao pogodak ukoliko je IoU veća od 0,5.

Ukoliko sa *T* označimo masku koja treba da se dobije, a sa *Y* prediktovanu masku. Na svakom pragu *t* preciznost *P(t)* se

računa korišćenjem sledećeg pravila:

$$P(t)=\begin{cases}0, & |T|=0 \wedge |Y|>0\\ 0, & |T|>0 \wedge |Y|=0\\ 1, & |T|=0 \wedge |Y|=0\\ IoU(T,Y)>t, & |T|>0 \wedge |Y|>0\end{cases} \quad (1)$$

Konačno, ocena kvaliteta prediktovane maske M se dobija usrednjavanjem rezultata po zadatih 10 pragova:

$$M=\frac{1}{10}\sum_{k=0}^{9}P(0{,}5+0{,}05k). \quad (2)$$

Pregled rezultata za različite konfiguracije u pogledu broja mreža koje čine ansambl i broja filtara u prvom sloju (parametar mreže n) je dat u Tabeli I. Pored privatnih rezultata koji su osnova za konačno rangiranje, prikazani su i javni rezultati koji su bili vidljivi i u toku trajanja takmičenja. Poređenja radi, u tabeli je prikazan i rezultat pobedničkog rešenja koje je opisano u [33], kao i autorovog prvog prijavljenog rešenja. Inače ukupan broj poslatih rešenja u toku takmičenja za pobednički tim iznosi 316, dok je u autorovom slučaju reč o 42 rešenja.

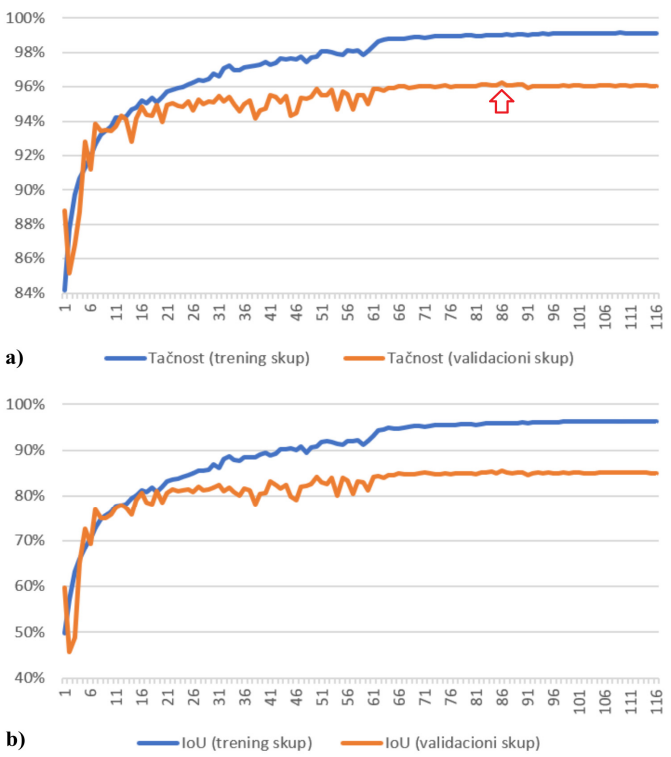
TABELA I
PREGLED REZULTATA ZA RAZLIČITE KONFIGURACIJE

Veličina ansambla	Broj filtara u prvom sloju / broj mreža	Javni rezultat	Privatni rezultat
5	16 / 5	0,82519	0,84525
5	24 / 5	0,82859	0,84771
5	32 / 5	0,83181	0,85087
10	24 / 5, 32 / 5	0,83314	0,85202
25	16 / 15, 24 / 5, 32 / 5	**0,83328**	**0,85241**
Rezultat pobedničkog rešenja		*0,88832*	*0,89646*
Rezultat prvog prijavljenog rešenja		*0,74828*	*0,76996*

U prikazanim rezultatima se mogu uočiti dva trenda. Jedan je da povećanje broja konvolucionih filtara pozitivno utiče na rezultat, a drugi je da se povećanje broja mreža u ansamblu takođe isplati. Inače, pošto korišćenje ansambla od 25 mreža nije baš uobičajena stvar, treba reći da je reč o poslednjem pokušaju da se popravi rezultat objedinjavanjem svega što je prethodno obučeno.

Ono što se iz rezultata ne vidi su svi drugi pokušaji koji nisu urodili plodom. Reč je o pokušajima sa drugim arhitekturama, korišćenjem drugačijih funkcija greške i drugačijih metrika za izbor najboljeg modela prilikom obučavanja, primena postprocesiranja korišćenjem morfoloških operacija, primena drugačijih načina za proširivanje podataka, itd.

Ilustracije radi, na slici 6 dat je prikaz toka obučavanja jedne od mreža u pogledu tačnost i IoU metrike.



Sl. 6. Grafikoni tačnosti (a) i IoU metrike (b) na nivou trening i validacionog skupa pri obučavanju pete mreže sa 32 inicijalna filtra.

V. ZAKLJUČAK

U radu je opisan metod za identifikaciju naslaga soli na seizmičkim snimcima korišćenjem duboke KNM za segmentaciju. Seizmičko snimanje i identifikacija naslaga soli je značajno zbog otkrivanja nalazišta nafte i zemnog gasa, a automatizacija ovog procesa je izuzetnog značaja za kompanije koje se bave istraživanjem nalazišta ovih energenata.

Rad je nastao učešćem autora na Kaggle takmičenju koje je sponzorisala kompanija TGS [1]. U radu je prikazano rešenje koje u konačnom plasmanu zauzelo 446 mesto od 3234 učesnika. U vreme kada je ovaj rad pisan, pojavio se i rad sa opisom prvoplasiranog rešenja [33]. Mnogo značajnije od konkretnog rešenja i plasmana je iskustvo stečeno učešćem u jednom ovakvom takmičenju.

Korišćenje takmičenja kao platforme za podsticaj i ubrzavanje naučnog i stručnog napretka već postaje oprobano rešenje. Setimo se samo do kakvog je napretka u rešavanju problema klasifikacije slika ImageNet takmičenje dovelo u svega nekoliko godina i kakav su uticaj rešenja koja su stasala na njemu imala na širu oblast. Kao učesnik TGS-ovog takmičenja, autor je bio svedok konstantnog pomeranja granica, kao opštih tako i ličnih. Čestitke pobednicima!

ZAHVALNICA

Prikazani rezultati dobijeni su u okviru istraživanja na

projektima III-43007 i III-47003 koje finansira Ministarstvo prosvete, nauke i tehnološkog razvoja Republike Srbije.

ABSTRACT

Several areas of Earth that are rich in oil and natural gas also have huge deposits of salt below the surface. Because of this connection, knowing precise locations of large salt deposits is extremely important to companies involved in oil and gas exploration. To locate salt bodies, professional seismic imaging is needed. These images are analyzed by human experts which leads to very subjective and highly variable renderings. To motivate automation and increase the accuracy of this process, a company TSG has sponsored Kaggle competition that was held in the second half of 2018 [1]. The competition was very popular gathering 3234 individuals and teams. In this paper, we present the author's contribution (446th place). The method presented in the paper relies on training a deep convolutional neural network for semantic segmentation. The architecture of the network is inspired by U-Net model in combination with ResNet and DenseNet architectures.

Identification of salt deposits on seismic images using deep learning method for semantic segmentation

***Abstract*— The objective of this study is to investigate the influence of the polyhedral oligo silsesquioxanes (POSS) structure on the adhesion behavior of composite films onto a metallic surface. The composite films consist of UV cured Bisphenol A glycidylmethacrylate/triethylene glycol dimethacrylate (Bis-GMA/TEGDMA) as matrix and reactive POSS structures as adhesion enhancers. Composites are made with 1, 3 and 5 wt. % of POSS particles. Adhesion is evaluated using the micro Vickers hardness testing method. The contact angle of hybrid films to the brass substrate is measured and compared to the adhesion parameter from micro hardness measurements. The shape and size of the indent are analyzed and correlated to the adhesion quality. Methods used in this paper for estimation of adhesion strength and quality clearly indicate that the best adhesion enhancer of Bis-GMA/TEGDMA matrix is POSS reagent containing both hydroxyl and allyl functional group.**

***Index Terms*— polyhedral oligo silsesquioxanes, hybrid materials, adhesion, acrylate.**

Radon exhalation from fly-ash geopolymer mortar

Luka Rubinjoni, Igor Čeliković, Gordana Tanasijević, Miroslav Komljenović, Boris Lončar

Abstract—Geopolymers are a type of alkali activated binders, inorganic aluminosilicate polymers with amorphous cross-linked structure. Fly-ash is produced in abundance during coal firing, and poses an environmental and health risk in untreated powder form. Fly-ash geopolymer presents a sustainable alternative to Portland cement, due to lower net greenhouse gas emissions. Presence of naturally occurring radioactive elements in fly-ash is one of the factors taken into account when estimating the safety of fly-ash based building materials. Radon, a radioactive noble gas originating from the decay of radium, can leave the material and contribute to internal dose in closed spaces, so radon exhalation is of special interest. Radon exhalation for a standard sample of fly-ash geopolymer mortar was measured.

***Index Terms*— geopolymer; fly-ash; radon exhalation**

The Strategy of Building and Using Simplified Robotic Models in Engineering Projects

Zorica Dodevska, Vladimir Kvrgic, Marko Mihic

***Abstract*—Building robotic models for the purposes of achieving goals in engineering projects, and its usage as a strategy advantage of such projects, are the main topics of this paper. Also, implementation of innovative technologies, like augmented reality (AR) and internet of things (IoT), on simplified robotic models (SRM) are at the focus in the paper. The authors find that the strategy of building and using SRM concept in complex engineering projects is fully justified, particularly before construction of the real objects that can be very expensive and time consuming. The fact that developed solutions (for example, AR apps) can be transferred to the final objects with necessary testing and modification strongly supports the authors' standing in this paper. Uniqueness of this work is reflected in the use of LEGO elements for building physical model of a centrifuge for pilot training, according to the project requirements, and developing an AR/IoT mobile app that could be applied to the real centrifuge. In addition to the strategy based on SRM, the authors stress the importance of such AR development strategy.**

***Index Terms*—Simplified robotic models; strategy; engineering projects; augmented reality; LEGO; centrifuge for pilot training.**
